Zabbix Manual

Welcome to the user manual for Zabbix software. These pages are created to help users successfully manage their monitoring tasks with Zabbix, from the simple to the more complex ones.

Copyright notice

Zabbix documentation is NOT distributed under the AGPL-3.0 license. Use of Zabbix documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Zabbix disseminates it (that is, electronically for download on a Zabbix web site) or on a USB or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Zabbix. Zabbix reserves any and all rights to this documentation not expressly granted above.

1 Introduction

Please use the sidebar to access content in the Introduction section.

1 Manual structure

Structure

The content of this manual is divided into sections and subsections to provide easy access to particular subjects of interest.

When you navigate to respective sections, make sure that you expand section folders to reveal full content of what is included in subsections and individual pages.

Cross-linking between pages of related content is provided as much as possible to make sure that relevant information is not missed by the users.

Sections

Introduction provides general information about current Zabbix software. Reading this section should equip you with some good reasons to choose Zabbix.

Zabbix definitions explain the terminology used in Zabbix, while **Zabbix processes** provides details on Zabbix components.

Installation and **Quickstart** sections should help you to get started with Zabbix. **Zabbix appliance** is an alternative for getting a quick taster of what it is like to use Zabbix.

Configuration is one of the largest and more important sections in this manual. It contains loads of essential advice about how to set up Zabbix to monitor your environment, from setting up hosts to getting essential data to viewing data to configuring notifications and remote commands to be executed in case of problems.

Service monitoring details how to use Zabbix for a high-level overview of your monitoring environment.

Web monitoring should help you learn how to monitor the availability of web sites.

Virtual machine monitoring presents a how-to for configuring VMware environment monitoring.

Maintenance, **Regular expressions**, **Problem acknowledgment** and **Configuration export/import** are further sections that reveal how to use these various aspects of Zabbix software.

Discovery contains instructions for setting up automatic discovery of network devices, active agents, file systems, network interfaces, etc.

Distributed monitoring deals with the possibilities of using Zabbix in larger and more complex environments.

Encryption helps explaining the possibilities of encrypting communications between Zabbix components.

Web interface contains information specific for using the web interface of Zabbix.

Best practices contain useful tips for optimal and secure user experience.

[API](#) section presents details of working with Zabbix API.

[Extensions](#) is a collection of ways for extending Zabbix.

Detailed lists of technical information are included in [Appendixes](#).

[Quick reference guides](#) contain step-by-step guides for accomplishing tasks with Zabbix.

2 What is Zabbix

Overview

Zabbix was created by Alexei Vladishev, and currently is actively developed and supported by Zabbix SIA.

Zabbix is an enterprise-class open source distributed monitoring solution.

Zabbix is a software that monitors numerous parameters of a network and the health and integrity of servers, virtual machines, applications, services, databases, websites, the cloud and more. Zabbix uses a flexible notification mechanism that allows users to configure email-based alerts for virtually any event. This allows a fast reaction to server problems. Zabbix offers excellent reporting and data visualization features based on the stored data. This makes Zabbix ideal for capacity planning.

Zabbix supports both polling and trapping. All Zabbix reports and statistics, as well as configuration parameters, are accessed through a web-based frontend. A web-based frontend ensures that the status of your network and the health of your servers can be assessed from any location. Properly configured, Zabbix can play an important role in monitoring IT infrastructure. This is equally true for small organizations with a few servers and for large companies with a multitude of servers.

Zabbix is free of cost. Zabbix is written and distributed under the AGPL-3.0 license. It means that its source code is freely distributed and available for the general public.

[Commercial support](#) is available and provided by Zabbix Company and its partners around the world.

Learn more about [Zabbix features](#).

Users of Zabbix

Many organizations of different size around the world rely on Zabbix as a primary monitoring platform.

3 Zabbix features

Overview

Zabbix is a highly integrated network monitoring solution, offering a multiplicity of features in a single package.

Data gathering

- availability and performance checks
- support for SNMP (both trapping and polling), IPMI, JMX, VMware monitoring
- custom checks
- gathering desired data at custom intervals
- performed by server/proxy and by agents

Flexible threshold definitions

- you can define very flexible problem thresholds, called triggers, referencing values from the backend database

Highly configurable alerting

- sending notifications can be customized for the escalation schedule, recipient, media type
- notifications can be made meaningful and helpful using macro variables
- automatic actions include remote commands

Real-time graphing

- monitored items are immediately graphed using the built-in graphing functionality

Web monitoring capabilities

- Zabbix can follow a path of simulated mouse clicks on a web site and check for functionality and response time

Extensive visualization options

- ability to create custom graphs that can combine multiple items into a single view
- network maps
- slideshows in a dashboard-style overview
- reports
- high-level (business) view of monitored resources

Historical data storage

- data stored in a database
- configurable history
- built-in housekeeping procedure

Easy configuration

- add monitored devices as hosts
- hosts are picked up for monitoring, once in the database
- apply templates to monitored devices

Use of templates

- grouping checks in templates
- templates can inherit other templates

Network discovery

- automatic discovery of network devices
- agent autoregistration
- discovery of file systems, network interfaces and SNMP OIDs

Fast web interface

- a web-based frontend in PHP
- accessible from anywhere
- you can click your way through
- audit log

Zabbix API

- Zabbix API provides programmable interface to Zabbix for mass manipulations, third-party software integration and other purposes.

Permissions system

- secure user authentication
- certain users can be limited to certain views

Full featured and easily extensible agent

- deployed on monitoring targets
- can be deployed on both Linux and Windows

Binary daemons

- written in C, for performance and small memory footprint
- easily portable

Ready for complex environments

- remote monitoring made easy by using a Zabbix proxy

4 Zabbix overview

Architecture

Zabbix consists of several major software components. Their responsibilities are outlined below.

Server

Zabbix server is the central component to which agents report availability and integrity information and statistics. The server is the central repository in which all configuration, statistical and operational data are stored.

Database storage

All configuration information as well as the data gathered by Zabbix is stored in a database.

Web interface

For an easy access to Zabbix from anywhere and from any platform, the web-based interface is provided. The interface is part of Zabbix server, and usually (but not necessarily) runs on the same physical machine as the one running the server.

Proxy

Zabbix proxy can collect performance and availability data on behalf of Zabbix server. A proxy is an optional part of Zabbix deployment; however, it may be very beneficial to distribute the load of a single Zabbix server.

Agent

Zabbix agents are deployed on monitoring targets to actively monitor local resources and applications and report the gathered data to Zabbix server. Since Zabbix 4.4, there are two types of agents available: the **Zabbix agent** (lightweight, supported on many platforms, written in C) and the **Zabbix agent 2** (extra-flexible, easily extendable with plugins, written in Go).

Data flow

In addition it is important to take a step back and have a look at the overall data flow within Zabbix. In order to create an item that gathers data you must first create a host. Moving to the other end of the Zabbix spectrum you must first have an item to create a trigger. You must have a trigger to create an action. Thus if you want to receive an alert that your CPU load is too high on *Server X* you must first create a host entry for *Server X* followed by an item for monitoring its CPU, then a trigger which activates if the CPU is too high, followed by an action which sends you an email. While that may seem like a lot of steps, with the use of templating it really isn't. However, due to this design it is possible to create a very flexible setup.

5 What's new in Zabbix 7.2.0

See **breaking changes** for this version.

Environment variables in configuration files

Zabbix components now support environment variables that allow configuring components without hardcoding values in configuration files. This makes it easy to manage configurations in dynamic environments, such as Docker, where variables can be passed at runtime to adapt to different setups.

Environment variables are supported by the following Zabbix components:

- **Server**
- **Proxy**
- Agent (**UNIX** or **Windows**)
- Agent 2 (**UNIX** or **Windows**), including **plugins**
- **Web service**
- Zabbix sender (when using the **-c, --config option**)

For details on environment variable configuration, syntax, examples, and limitations, see **Environment variables**.

More efficient low-level discovery

The performance of low-level discovery processes has been significantly improved, ensuring faster discovery, updating, and deletion of entities. As a result, the previously enforced limits have been removed, allowing configurations with an unlimited number of **dependent items** and item dependency levels.

Widgets

Host card

A new **Host card** widget has been added, offering a convenient way to view comprehensive information about a single host at a glance.

Server database

115

Web 0

Availability

ZBX

Monitored by

Zabbix server

class: database

location: new-york

target: mysql

Top items

A new **Top items** widget has been added, replacing the functionality of the deprecated *Data overview* widget.

| Top items | |
|---------------------|---------------|
| Items | Zabbix server |
| CPU idle time | 74.45 % |
| CPU utilization | 25.55 % |
| CPU system time | 12.93 % |
| CPU user time | 8.56 % |
| CPU softirq time | 2.15 % |
| CPU iowait time | 1.02 % |
| CPU guest nice time | 0.00 % |

In addition to functionality inherited from the *Data overview* widget, in *Top items* it is possible to select items by pattern, customize column ordering and highlighting.

Sparkline charts in Item value widget

The **Item value** widget now supports sparkline charts. These compact line graphs provide an at-a-glance overview of value dynamics, making it easier to monitor changes effectively.

Improved column control in Top hosts widget

The **Top hosts** widget now provides more variety for configuring the item value columns:

| Top hosts by available memory % | | | | | | | |
|---------------------------------|---|-----------|---|----------|---|------|-------------------------|
| Host | Available memory | | Available memory in % | Load avg | Contact | | |
| Server node 1 |  | 7.33 GB |  | 95 % |  | 0.86 | admin@company.com |
| Zabbix server |  | 6.66 GB |  | 86 % |  | 0.86 | admin@company.com |
| Server node 2 |  | 3.34 GB |  | 43 % |  | 1.29 | admin@company.com |
| Web server |  | 2.00 GB |  | 26 % |  | 1.58 | web_service@company.com |
| Virtual machine 2 |  | 1.33 GB |  | 13 % |  | 0.86 | vm_admin@company.com |
| Virtual machine 1 |  | 681.99 MB |  | 9 % |  | 1.46 | vm_admin@company.com |

- Numeric item values can be displayed as sparkline charts - the compact line graphs for visualizing value dynamics.
- The binary item value format, not supported previously, can be used to show a thumbnail or a hyperlink to the full size image in the respective column.
- For the text item value format, it is now possible to specify a regular expression upon matching which the column will change background color.

Graph widget enhancements

The **Graph** widget offers two usability enhancements:

- The widget's Y-axis now supports logarithmic scaling, suitable for data that changes rapidly or covers a large range.
- A new configuration parameter *Override host* has been added to enable dynamic host selection from the dashboard or a compatible widget.

Dynamic unit size in Clock widget

The **Clock** widget's digital clock information unit (date, time, time zone) size now dynamically adjusts to fill all available space based on displayed units, widget size, and display scaling. Configuration parameters for setting the unit size have been removed.

Items

- A new item `vmware.vm.hv.maintenance[]` has been added for monitoring VMware virtual machine hypervisor maintenance status.
- The `ssh.run[]` item now supports the `PubkeyAcceptedKeyTypes` SSH option and a new `<subsystem>` optional parameter, which allows the use of SSH subsystems (e.g., SFTP, NETCONF).
- The `systemd.unit.discovery[]` item now returns the macro `{#UNIT.SERVICETYPE}` which specifies the behavior of the service unit (e.g., simple, forking, oneshot, idle, etc.).
- The `system.cpu.util[]` item now supports a new type `spin` on OpenBSD for returning `CP_SPIN` CPU state.

Macros

New macros are now supported:

- `{TIMESTAMP}`, `{EVENT.TIMESTAMP}`, `{EVENT.RECOVERY.TIMESTAMP}`, `{EVENT.UPDATE.TIMESTAMP}`, `{EVENT.CAUSE.TIMESTAMP}`, `{ITEM.LOG.TIMESTAMP}` resolve to the current time in Unix timestamp format;

- {EVENT.UPDATE.ACTIONJSON} resolves to a JSON array containing details of the action(s) performed during a problem update;
- {SERVICE.ID} resolves to the numeric ID of the service that triggered the action.

The following macros have been updated:

- {HOST.PORT} is now supported in the same locations as {HOST.CONN} (except for the trapper item and HTTP agent item *Allowed hosts* field and host interface IP/DNS).
- The macros {FUNCTION.VALUE<1-9>} and {FUNCTION.RECOVERY.VALUE<1-9>} are now supported inside the **expression macros** allowing to reference values of the trigger expressions.

For more details, see [Supported macros](#).

Direct web links to modal forms

Modal forms for a host, item, trigger, etc., when opened, now have their own link making it possible to link directly to the item or trigger in problem-related notification messages or share a link.

For example, a modal form link for an item may look like this:

```
<path-to-zabbix-ui>/zabbix.php?action=popup&popup=item.edit&context=host&itemid=42243
```

Additionally, it is now possible to open any modal form in a new tab. When opened in a new tab, the form is opened on a gray background.

Repository structure

In the official [Zabbix repository](#), packages for versions that haven't been officially released yet are now available in the `.../7.2/unstable` folder, offering early access to the new features. The stable, officially released packages are stored in the `.../7.2/stable` folder, while the *zabbix-release* packages — usable for both stable and unstable versions — are provided separately in the `.../7.2/release` folder.

Starting with version 7.2, the *non-supported* folder has been renamed to *third-party*. This updated folder now contains customized packages specifically for RHEL and its derivative distributions, streamlining access to tailored solutions for these platforms.

6 What's new in Zabbix 7.2.1

Identifying items with highest preprocessing task queue

A `top.peak` property has been added to the **diagnfo** output allowing to identify items with the highest preprocessing task queue.

NVIDIA GPU plugin

A Zabbix agent 2 loadable plugin for monitoring NVIDIA GPU metrics is [now available](#).

Templates

For changes to existing templates and information on new templates, see [Template changes](#).

7 What's new in Zabbix 7.2.2

This minor version has no functional changes.

8 What's new in Zabbix 7.2.3

See [breaking changes](#) for this version.

History, trends and audit log compression settings

The *History and trends compression* block has been renamed to *History, trends and audit log compression* in the Administration > Housekeeping section of the Zabbix frontend, accessible after [installing or updating TimescaleDB](#).

9 What's new in Zabbix 7.2.4

See [breaking changes](#) for this version.

PHP support

The maximum supported version for PHP is now 8.4.

TimescaleDB 2.18 support

The maximum [supported version](#) for TimescaleDB is now 2.18.X.

Host availability status calculation

The [availability](#) status of all host interfaces of a single type (Agent, SNMP, IPMI, JMX) is now determined only by those interfaces that are used by at least one enabled item. It is no longer determined by all interfaces of the same type, regardless of whether any items use them.

Information column in action list

An *Info* column has been added to the [action list](#). If everything is working correctly, nothing is displayed in this column. In case of errors, such as missing action operations or conditions after upgrade/low-level discovery, a warning icon is displayed. You can hover over the icon to see a tooltip with the error description.

Additionally, actions are no longer being disabled:

- if a user deletes objects used in action conditions or operations;
- if objects used in action conditions or operations are no longer discovered by low-level discovery and have been removed (after the *Delete lost resources* period).

Now, when attempting to delete objects that are used in action conditions or operations, the user will receive a corresponding error message. Previously, objects were simply deleted without any warning and the action was disabled, which was not entirely transparent.

User parameter added to Redis Zabbix agent 2 plugin

In the [Redis Zabbix agent 2 plugin](#) configuration file, the `User` parameter now allows specifying a username for authenticating with Redis servers that use Access Control Lists (ACLs), which provides an alternative to using a global administrator password.

Templates

For changes to existing templates and information on new templates, see [Template changes](#).

10 What's new in Zabbix 7.2.5

Asynchronous DNS resolution

The agent poller and SNMP poller can now be configured to use the *c-ares* library (version 1.16.0 or newer) instead of the *libevent* DNS resolver. This allows for potentially faster and more flexible DNS resolution.

To enable *c-ares*, Zabbix must be [configured](#) with the `--with-ares` option.

Note that starting from *c-ares* 1.31.0, DNS caching is enabled by default.

Webhook integrations updated

The following out-of-the-box webhooks now support all event types and have been improved for code efficiency, maintainability, and functionality, with changes reflected in the documentation:

- [Discord](#) - script updated to use Discord API v10; hardcoded custom message format for trigger-based events removed.
- [GitHub](#) - GitHub API version parameter introduced to use a static version instead of the latest; in cases of escalation, existing issues are now updated instead of new ones being created; issue labels and adjustable prefixes in webhook parameters added.
- [GLPI](#) - message templates updated.
- [Jira](#) - trigger and service actions now support mapping of Zabbix event severities to Jira ticket priorities (via parameters `severity_information`, `severity_high`, etc.); support for custom Jira priorities added to all autoregistration, discovery, and internal actions (via parameters `jira_priority_discovery`, `jira_priority_autoregistration`, `jira_priority_internal`); Jira custom fields for ticket creation added to all actions (previously only trigger); problem event messages are now sent to the Jira ticket description, and default OK event messages are now added as comments.

- [Jira Service Management](#) (previously Jira Service Desk) - trigger and service actions now support mapping of Zabbix event severities to Jira ticket priorities; support for custom Jira priorities added to all autoregistration, discovery, and internal actions; Jira custom fields for ticket creation added to all actions (previously only trigger); support added for date and time, radio button, checkbox, single and multiple choice custom fields; URL custom field behavior adjusted; support for ticket labels added and issue name format updated to match the [Jira](#) media type; both private (default) and public comment options now available for escalations; in cases where event severity is updated between escalations, task priority no longer reverts to the original.
- [MS Teams](#) - message templates updated.
- [OTRS CE](#) - support added for closing incidents of resolved problems.
- [PagerDuty](#) - support added for closing incidents of resolved problems; API token moved to user media settings via `{ALERT.SENDTO}`.
- [Slack](#) - deprecated parameter `slack_as_user` removed; templates implemented for messages sent to Slack.
- [Telegram](#) - support for reply messages added.
- [Zammad](#) - previously hardcoded user group “Users” moved to a webhook parameter; event tags no longer created by default.

SMART plugin for Zabbix agent 2 updated

The `smart.disk.get` item key in the [SMART Zabbix agent 2 plugin](#) now returns both raw and normalized values for SMART attributes.

Performance improvements

Trend update performance on TimescaleDB has been increased by using upserts instead of updates.

Zabbix server performance has been enhanced by implementing parallel syncing of trends and avoiding range queries, resulting in faster shutdown times on MySQL, PostgreSQL and TimescaleDB.

Templates

For changes to existing templates and information on new templates, see [Template changes](#).

Improved layout for “Custom on fail” option in item preprocessing

The [item value preprocessing](#) tab’s “Custom on fail” options are now displayed correctly in all supported language localizations. Previously, misalignment in some translations led to configuration ambiguity when setting custom error-handling actions for preprocessing steps. With this fix the control is rendered consistently, and after selecting the “Custom on fail” checkbox the available options are now presented as a dropdown list instead of radio buttons — providing a clearer and more compact interface.

17 What’s new in Zabbix 7.2.6

Preprocessing throughput internal item

A new [zabbix\[preprocessing\]](#) internal item has been added that returns a JSON containing statistics of the values received by the preprocessing manager:

- *queued* - the number and size of queued values that require preprocessing (counter);
- *direct* - the number and size of queued values that do not require preprocessing (counter);
- *queue* - the count of values enqueued in the preprocessing queue (same as `zabbix[preprocessing_queue]`)

Enhanced precision in `net.dns.get` query time

The `net.dns.get` item now reports the `query_time` attribute with microsecond precision, increasing from two to six decimal places. For more details on the return values, refer to the [Return values for net.dns.get](#) page.

MSSQL plugin for Zabbix agent 2 updated

In the [MSSQL plugin for Zabbix agent 2](#), the item `mssql.last.backup.get` has been updated to exclude non-existing databases from the query.

ListenPort behavior in Zabbix agent 2 /status endpoint

When passive checks are disabled in Zabbix agent 2 [configuration](#), the `ListenPort` parameter no longer has a value.

Templates

For changes to existing templates and information on new templates, see [Template changes](#).

18 What's new in Zabbix 7.2.7

TimescaleDB 2.19 support

The maximum **supported version** for TimescaleDB is now 2.19.X.

PostgreSQL plugin for Zabbix agent 2 updated

The **PostgreSQL Zabbix agent 2 plugin** has been updated for compatibility with PostgreSQL 17 and now uses the new `pg_stat_checkpoint` system view for checkpoint statistics (previously `pg_stat_bgwriter`).

VMware datastore discovery

The item **`vmware.datastore.discovery[]`** now supports filtering by hypervisor or virtual machine unique ID.

Secret macro resolution

Secret user macro values will now remain masked in **locations** that support secret macro resolution if they are referenced indirectly. For example, `{ITEM.KEY}`, `{ITEM.KEY<1-9>}`, `{LLDRULE.KEY}` built-in macros used in media types (Script or Webhook parameters) will resolve to item keys containing masked secret macros, such as `net.tcp.port[*****,****]` instead of `net.tcp.port[192.0.2.0,80]`.

Templates

For changes to existing templates and information on new templates, see **Template changes**.

19 What's new in Zabbix 7.2.8

SNMP walk and get retries increased

SNMP agent walk and get items now make up to 5 retries (instead of 1) to retrieve all values if previous attempts time out or fail. Each retry resets the timeout and resumes from the last successful request, improving data reliability in case of packet loss or delayed responses during SNMP data collection.

Consider setting a low timeout in the **item configuration** form to avoid long delays if the device is unreachable (e.g., 3-second timeout can result in 15-second wait time).

Webhook integrations updated

The following out-of-the-box webhooks have been updated, with changes reflected in the documentation:

- **OTRS CE** - ticket type parameter and missing web service file added.
- **Telegram** - support for supergroup topics added.

Oracle Database plugin for Zabbix agent 2 updated

The **Oracle Database plugin** for Zabbix agent 2 now supports both the container name and container ID in the `connname` parameter of the `oracle.ts.stats` key.

Templates

For changes to existing templates and information on new templates, see **Template changes**.

20 What's new in Zabbix 7.2.9

This minor version has no functional changes.

21 What's new in Zabbix 7.2.10

This minor version has no functional changes.

2 Definitions

Overview In this section you can learn the meaning of some terms commonly used in Zabbix.

Definitions *host*

- any physical or virtual device, application, service, or any other logically-related collection of monitored parameters.

host group

- a logical grouping of hosts. Host groups are used when assigning access rights to hosts for different user groups.

item

- a particular piece of data that you want to receive from a host, a metric of data.

value preprocessing

- a transformation of received metric value before saving it to the database.

trigger

- a logical expression that defines a problem threshold and is used to "evaluate" data received in items.

When received data are above the threshold, triggers go from 'Ok' into a 'Problem' state. When received data are below the threshold, triggers stay in/return to an 'Ok' state.

template

- a set of entities (items, triggers, graphs, low-level discovery rules, web scenarios) ready to be applied to one or several hosts.

The job of templates is to speed up the deployment of monitoring tasks on a host; also to make it easier to apply mass changes to monitoring tasks. Templates are linked directly to individual hosts.

template group

- a logical grouping of templates. Template groups are used when assigning access rights to templates for different user groups.

event

- a single occurrence of something that deserves attention such as a trigger changing state or a discovery/agent autoregistration taking place.

event tag

- a pre-defined marker for the event. It may be used in event correlation, permission granulation, etc.

event correlation

- a method of correlating problems to their resolution flexibly and precisely.

For example, you may define that a problem reported by one trigger may be resolved by another trigger, which may even use a different data collection method.

problem

- a trigger that is in "Problem" state.

problem update

- problem management options provided by Zabbix, such as adding comment, acknowledging, changing severity or closing manually.

action

- a predefined means of reacting to an event.

An action consists of operations (e.g. sending a notification) and conditions (when the operation is carried out)

escalation

- a custom scenario for executing operations within an action; a sequence of sending notifications/executing remote commands.

media

- a means of delivering notifications; delivery channel.

notification

- a message about some event sent to a user via the chosen media channel.

remote command

- a pre-defined command that is automatically executed on a monitored host upon some condition.

web scenario

- one or several HTTP requests to check the availability of a web site.

frontend

- the web interface provided with Zabbix.

dashboard

- customizable section of the web interface displaying summaries and visualizations of important information in visual units called widgets.

widget

- visual unit displaying information of a certain kind and source (a summary, a map, a graph, the clock, etc.), used in the dashboard.

Zabbix API

- Zabbix API allows you to use the JSON RPC protocol to create, update and fetch Zabbix objects (like hosts, items, graphs and others) or perform any other custom tasks.

Zabbix server

- a central process of Zabbix software that performs monitoring, interacts with Zabbix proxies and agents, calculates triggers, sends notifications; a central repository of data.

Zabbix proxy

- a process that may collect data on behalf of Zabbix server, taking some processing load from the server.

Zabbix agent

- a process deployed on monitoring targets to actively monitor local resources and applications.

Zabbix agent 2

- a new generation of Zabbix agent to actively monitor local resources and applications, allowing to use custom plugins for monitoring.

Attention:

Because Zabbix agent 2 shares much functionality with Zabbix agent, the term "Zabbix agent" in documentation stands for both - Zabbix agent and Zabbix agent 2, if the functional behavior is the same. Zabbix agent 2 is only specifically named where its functionality differs.

encryption

- support of encrypted communications between Zabbix components (server, proxy, agent, zabbix_sender and zabbix_get utilities) using Transport Layer Security (TLS) protocol.

agent autoregistration

- automated process whereby a Zabbix agent itself is registered as a host and started to monitor.

network discovery

- automated discovery of network devices.

low-level discovery

- automated discovery of low-level entities on a particular device (e.g. file systems, network interfaces, etc).

low-level discovery rule

- set of definitions for automated discovery of low-level entities on a device.

item prototype

- a metric with certain parameters as variables, ready for low-level discovery. After low-level discovery the variables are automatically substituted with the real discovered parameters and the metric automatically starts gathering data.

trigger prototype

- a trigger with certain parameters as variables, ready for low-level discovery. After low-level discovery the variables are automatically substituted with the real discovered parameters and the trigger automatically starts evaluating data.

Prototypes of some other Zabbix entities are also in use in low-level discovery - graph prototypes, host prototypes, host group prototypes.

3 Zabbix processes

Please use the sidebar to access content in the Zabbix process section.

1 Server

Overview

Zabbix server is the central process of Zabbix software.

The server performs the polling and trapping of data, it calculates triggers, sends notifications to users. It is the central component to which Zabbix agents and proxies report data on availability and integrity of systems. The server can itself remotely check networked services (such as web servers and mail servers) using simple service checks.

The server is the central repository in which all configuration, statistical and operational data is stored, and it is the entity in Zabbix that will actively alert administrators when problems arise in any of the monitored systems.

The functioning of a basic Zabbix server is broken into three distinct components; they are: Zabbix server, web frontend and database storage.

All of the configuration information for Zabbix is stored in the database, which both the server and the web frontend interact with. For example, when you create a new item using the web frontend (or API) it is added to the items table in the database. Then, about once a minute Zabbix server will query the items table for a list of the items which are active that is then stored in a cache within the Zabbix server. This is why it can take up to two minutes for any changes made in Zabbix frontend to show up in the latest data section.

Running server

If installed as package

Zabbix server runs as a daemon process. The server can be started by executing:

```
systemctl start zabbix-server
```

This will work on most of GNU/Linux systems. On other systems you may need to run:

```
/etc/init.d/zabbix-server start
```

Similarly, for stopping/restarting/viewing status, use the following commands:

```
systemctl stop zabbix-server
systemctl restart zabbix-server
systemctl status zabbix-server
```

Start up manually

If the above does not work you have to start it manually. Find the path to the zabbix_server binary and execute:

```
zabbix_server
```

You can use the following command-line parameters with Zabbix server:

| | |
|-------------------------------|---|
| -c --config <file> | path to the configuration file (default is /usr/local/etc/zabbix_server.conf) |
| -f --foreground | run Zabbix server in foreground |
| -R --runtime-control <option> | perform administrative functions |
| -T --test-config | validate configuration file and exit |
| -h --help | give this help |
| -V --version | display version number |

Examples of running Zabbix server with command-line parameters:

```
zabbix_server -c /usr/local/etc/zabbix_server.conf
zabbix_server --help
zabbix_server -V
```

Runtime control

Runtime control options:

| Option | Description | Target |
|--|---|--|
| config_cache_reload | Reload configuration cache. Ignored if cache is being currently loaded. | |
| diaginfo[=<section>] | Gather diagnostic information in the server log file. | historycache - history cache statistics valuecache - value cache statistics preprocessing - preprocessing manager statistics alerting - alert manager statistics lld - LLD manager statistics locks - list of mutexes (is empty on <i>BSD</i> systems) connector - statistics for connectors with the largest queue |
| ha_status | Log high availability (HA) cluster status. | |
| ha_remove_node=tag | Remove the high availability (HA) node specified by its name or ID. Note that active/standby nodes cannot be removed. | target - name or ID of the node (can be obtained by running <code>ha_status</code>) |
| ha_set_failover_delay=tag | Set high availability (HA) failover delay. Time suffixes are supported, e.g. 10s, 1m. | |
| proxy_config_cache_reload[proxytarget] | Reload proxy configuration cache. | target - comma-delimited list of proxy names If no target is specified, reload configuration for all proxies |
| secrets_reload | Reload secrets from Vault. | |
| service_cache_reload | Reload the service manager cache. | |
| snmp_cache_reload | Reload SNMP cache, clear the SNMP properties (engine time, engine boots, engine id, credentials) for all hosts. | |
| housekeeper_execute | Start the housekeeping procedure. Ignored if the housekeeping procedure is currently in progress. | |
| trigger_housekeeper_execute | Start the trigger housekeeping procedure for services to remove problems caused by triggers that have since been deleted, including service problems generated by such problems (considered as resolved at the time of housekeeping). Note that, until the housekeeping procedure is started, problems caused by now-deleted triggers might still generate service problems and assign them to services. If your setup involves many service status calculation rules based on frequently discovered/undiscovered triggers, consider increasing the frequency of the trigger housekeeping procedure by adjusting the ProblemHousekeepingFrequency server configuration parameter. Ignored if the trigger housekeeping procedure is currently in progress. | |

| Option | Description | Target |
|--|---|--|
| log_level_increase[= target] | Increases log level, affects all processes if target is not specified. Not supported on <i>BSD</i> systems. | process type - All processes of specified type (e.g., poller) See all server process types . process type,N - Process type and number (e.g., poller,3) pid - Process identifier (1 to 65535). For larger values specify target as 'process type,N'. |
| log_level_decrease[= target] | Decreases log level, affects all processes if target is not specified. Not supported on <i>BSD</i> systems. | |
| prof_enable[= target] | Enable profiling. Affects all processes if target is not specified. Enabled profiling provides details of all rwlocks/mutexes by function name. | process type - All processes of specified type (e.g. history syncer) Supported process types as profiling targets: alerter, alert manager, availability manager, configuration syncer, discovery manager, escalator, history poller, history syncer, housekeeper, http poller, icmp pinger, ipmi manager, ipmi poller, java poller, lld manager, lld worker, odbc poller, poller, preprocessing manager, preprocessing worker, proxy poller, self-monitoring, service manager, snmp trapper, task manager, timer, trapper, unreachable poller, vmware collector process type,N - Process type and number (e.g., history syncer,1) pid - Process identifier (1 to 65535). For larger values specify target as 'process type,N'. scope - rwlock, mutex, processing can be used with the process type and number (e.g., history syncer,1,processing) or all processes of type (e.g., history syncer,rwlock) |
| prof_disable[= target] | Disable profiling. Affects all processes if target is not specified. | process type - All processes of specified type (e.g. history syncer) Supported process types as profiling targets: see prof_enable process type,N - Process type and number (e.g., history syncer,1) pid - Process identifier (1 to 65535). For larger values specify target as 'process type,N'. |

Example of using runtime control to reload the server configuration cache:

```
zabbix_server -c /usr/local/etc/zabbix_server.conf -R config_cache_reload
```

Examples of using runtime control to reload the proxy configuration:

```
# Reload configuration of all proxies:
```

```
zabbix_server -R proxy_config_cache_reload
```

```
# Reload configuration of Proxy1 and Proxy2:
```

```
zabbix_server -R proxy_config_cache_reload=Proxy1,Proxy2
```

Examples of using runtime control to gather diagnostic information:

```
# Gather all available diagnostic information in the server log file:
```

```
zabbix_server -R diaginfo
```

```
# Gather history cache statistics in the server log file:
```

```
zabbix_server -R diaginfo=historycache
```

Example of using runtime control to reload the SNMP cache:

```
zabbix_server -R snmp_cache_reload
```

Example of using runtime control to trigger execution of housekeeper:

```
zabbix_server -c /usr/local/etc/zabbix_server.conf -R housekeeper_execute
```

Examples of using runtime control to change log level:

```
# Increase log level of all processes:
```

```
zabbix_server -c /usr/local/etc/zabbix_server.conf -R log_level_increase
```

```
# Increase log level of second poller process:
```

```
zabbix_server -c /usr/local/etc/zabbix_server.conf -R log_level_increase=poller,2
```

```
# Increase log level of process with PID 1234:
```

```
zabbix_server -c /usr/local/etc/zabbix_server.conf -R log_level_increase=1234
```

```
# Decrease log level of all http poller processes:
```

```
zabbix_server -c /usr/local/etc/zabbix_server.conf -R log_level_decrease="http poller"
```

Example of setting the HA failover delay to the minimum of 10 seconds:

```
zabbix_server -R ha_set_failover_delay=10s
```

Process user

Zabbix server is designed to run as a non-root user. It will run as whatever non-root user it is started as. So you can run server as any non-root user without any issues.

If you will try to run it as 'root', it will switch to a hardcoded 'zabbix' user, which must be **present** on your system. You can only run server as 'root' if you modify the 'AllowRoot' parameter in the server configuration file accordingly.

If Zabbix server and **agent** are run on the same machine it is recommended to use a different user for running the server than for running the agent. Otherwise, if both are run as the same user, the agent can access the server configuration file and any Admin level user in Zabbix can quite easily retrieve, for example, the database password.

Configuration file

See the **configuration file** options for details on configuring zabbix_server.

Start-up scripts

The scripts are used to automatically start/stop Zabbix processes during system's start-up/shutdown. The scripts are located under directory misc/init.d.

Server process types and threads

- **agent poller** - asynchronous poller process for passive checks with a worker thread
- **alert manager** - alert queue manager
- **alert syncer** - alert DB writer
- **alerter** - process for sending notifications
- **availability manager** - process for host availability updates
- **browser poller** - poller for browser item checks
- **configuration syncer** - process for managing in-memory cache of configuration data
- **configuration syncer worker** - process for resolving and synchronizing user macro values in item names
- **connector manager** - manager process for connectors
- **connector worker** - process for handling requests from the connector manager
- **discovery manager** - manager process for discovery of devices
- **discovery worker** - process for handling discovery tasks from the discovery manager
- **escalator** - process for escalation of actions
- **ha manager** - process for managing high availability
- **history poller** - process for handling calculated checks requiring a database connection
- **history syncer** - history DB writer
- **housekeeper** - process for removal of old historical data
- **http agent poller** - asynchronous poller process for HTTP checks with a worker thread
- **http poller** - web monitoring poller
- **icmp pinger** - poller for icmping checks
- **internal poller** - poller for internal checks
- **ipmi manager** - IPMI poller manager
- **ipmi poller** - poller for IPMI checks
- **java poller** - poller for Java checks
- **lld manager** - manager process of low-level discovery tasks
- **lld worker** - worker process of low-level discovery tasks
- **odbc poller** - poller for ODBC checks

- `poller` - normal poller for passive checks
- `preprocessing_manager` - manager of preprocessing tasks with preprocessing worker threads
- `preprocessing_worker` - thread for data preprocessing
- `proxy_poller` - poller for passive proxies
- `proxy_group_manager` - manager of proxy load balancing and high availability
- `report_manager` - manager of scheduled report generation tasks
- `report_writer` - process for generating scheduled reports
- `self-monitoring` - process for collecting internal server statistics
- `service_manager` - process for managing services by receiving information about problems, problem tags, and problem recovery from history syncer, task manager, and alert manager
- `snmp_poller` - asynchronous poller process for SNMP checks with a worker thread (`walk[OID]` and `get[OID]` items only)
- `snmp_trapper` - trapper for SNMP traps
- `task_manager` - process for remote execution of tasks requested by other components (e.g., close problem, acknowledge problem, check item value now, remote command functionality)
- `timer` - timer for processing maintenances
- `trapper` - trapper for active checks, traps, proxy communication
- `trigger_housekeeper` - process for removing problems generated by triggers that have been deleted
- `unreachable_poller` - poller for unreachable devices
- `vmware_collector` - VMware data collector responsible for data gathering from VMware services

The server log file can be used to observe these process types.

Various types of Zabbix server processes can be monitored using the **`zabbix[process,<type>,<mode>,<state>]`** internal **item**.

Supported platforms

Due to the security requirements and mission-critical nature of server operation, UNIX is the only operating system that can consistently deliver the necessary performance, fault tolerance and resilience. Zabbix operates on market leading versions.

Zabbix server is tested on the following platforms:

- Linux
- Solaris
- AIX
- HP-UX
- Mac OS X
- FreeBSD
- OpenBSD
- NetBSD
- SCO Open Server

Note:

Zabbix may work on other Unix-like operating systems as well.

Locale

Note that the server requires a UTF-8 locale so that some textual items can be interpreted correctly. Most modern Unix-like systems have a UTF-8 locale as default, however, there are some systems where that may need to be set specifically.

1 High availability

Overview

High availability (HA) is typically required in critical infrastructures that can afford virtually no downtime. So for any service that may fail there must be a failover option in place to take over should the current service fail.

Zabbix offers a **native** high-availability solution that is easy to set up and does not require any previous HA expertise. Native Zabbix HA may be useful for an extra layer of protection against software/hardware failures of Zabbix server or to have less downtime due to maintenance.

In the Zabbix high availability mode multiple Zabbix servers are run as nodes in a cluster. While one Zabbix server in the cluster is active, others are on standby, ready to take over if necessary.

Switching to Zabbix HA is non-committal. You may switch back to standalone operation at any point.

See also: [Implementation details](#)

Enabling high availability

Starting Zabbix server as cluster node

Two parameters are required in the server [configuration](#) to start a Zabbix server as cluster node:

- **HANodeName** parameter must be specified for each Zabbix server that will be an HA cluster node.

This is a unique node identifier (e.g. `zabbix-node-01`) that the server will be referred to in agent and proxy configurations. If you do not specify `HANodeName`, then the server will be started in standalone mode.

- **NodeAddress** parameter must be specified for each node.

The `NodeAddress` parameter (`address:port`) will be used by Zabbix frontend to connect to the active server node. `NodeAddress` must match the IP or FQDN name of the respective Zabbix server.

Restart all Zabbix servers after making changes to the configuration files. They will now be started as cluster nodes. The new status of the servers can be seen in *Reports* → [System information](#) and also by running:

```
zabbix_server -R ha_status
```

This runtime command will log the current HA cluster status into the Zabbix server log (and to stdout):

```
Failover delay: 60 seconds
Cluster status:
# ID Name Address Status Last Access
1. ckzxxqg7u0001lsropeyhz3m zabbix-node-01 64.227.66.193:10051 standby 0s
2. ckzxyqo1k00013frpq539e1jp zabbix-node-02 64.227.74.25:10051 active 3s
```

Preparing frontend

Make sure that Zabbix server `address:port` is **not defined** in the frontend configuration (found in `conf/zabbix.conf.php` of the frontend files directory).

```
// Uncomment and set to desired values to override Zabbix hostname/IP and port.
// $ZBX_SERVER = '';
// $ZBX_SERVER_PORT = '';
```

Zabbix frontend will autodetect the active node by reading settings from the nodes table in Zabbix database. Node address of the active node will be used as the Zabbix server address.

Proxy configuration

HA cluster nodes (servers) must be listed in the configuration of either passive or active Zabbix proxy.

For a passive proxy, the node names must be listed in the `Server` [parameter](#) of the proxy, separated by a **comma**.

```
Server=zabbix-node-01,zabbix-node-02
```

For an active proxy, the node names must be listed in the `Server` [parameter](#) of the proxy, separated by a **semicolon**.

```
Server=zabbix-node-01;zabbix-node-02
```

Agent configuration

HA cluster nodes (servers) must be listed in the configuration of Zabbix agent or Zabbix agent 2.

To enable passive checks, the node names must be listed in the `Server` parameter, separated by a **comma**.

```
Server=zabbix-node-01,zabbix-node-02
```

To enable active checks, the node names must be listed in the `ServerActive` parameter. Note that for active checks the nodes must be separated by a comma from any other servers, while the nodes themselves must be separated by a **semicolon**, e.g.:

```
ServerActive=zabbix-node-01;zabbix-node-02
```

Failover to standby node

Zabbix will fail over to another node automatically if the active node stops. There must be at least one node in standby status for the failover to happen.

How fast will the failover be? All nodes update their last access time (and status, if it is changed) every 5 seconds. So:

- If the active node shuts down and manages to report its status as "stopped", another node will take over within **5 seconds**.
- If the active node shuts down/becomes unavailable without being able to update its status, standby nodes will wait for the **failover delay + 5 seconds** to take over

The failover delay is configurable, with the supported range between 10 seconds and 15 minutes (one minute by default). To change the failover delay, you may run:

```
zabbix_server -R ha_set_failover_delay=5m
```

Managing HA cluster

The current status of the HA cluster can be managed using the dedicated **runtime control** options:

- `ha_status` - log HA cluster status in the Zabbix server log (and to stdout)
- `ha_remove_node=target` - remove an HA node identified by its <target> - name or ID of the node (name/ID can be obtained from the output of running `ha_status`), e.g.:

```
zabbix_server -R ha_remove_node=zabbix-node-02
```

Note that active/standby nodes cannot be removed.

- `ha_set_failover_delay=delay` - set HA failover delay (between 10 seconds and 15 minutes; time suffixes are supported, e.g. 10s, 1m)

Node status can be monitored:

- in *Reports* → *System information*
- in the *System information* dashboard widget
- using the `ha_status` runtime control option of the server (see above).

The `zabbix[cluster,discovery,nodes]` internal item can be used for node discovery, as it returns a JSON with the high-availability node information.

Disabling HA cluster

To disable a high availability cluster:

- make backup copies of configuration files
- stop standby nodes
- remove the `HANodeName` parameter from the active primary server
- restart the primary server (it will start in standalone mode)

Upgrading HA cluster

To perform a major version upgrade for the HA nodes:

- stop all nodes;
- create a full database backup;
- if the database uses replication make sure that all nodes are in sync and have no issues. Do not upgrade if replication is broken.
- select a single node that will perform database upgrade, change its configuration to standalone mode by commenting out `HANodeName` and **upgrade** it;
- make sure that database upgrade is fully completed (*System information* should display that Zabbix server is running);
- restart the node in HA mode;
- upgrade and start the rest of nodes (it is not required to change them to standalone mode as the database is already upgraded at this point).

In a minor version upgrade it is sufficient to upgrade the first node, make sure it has upgraded and running, and then start upgrade on the next node.

Implementation details

The high availability (HA) cluster is an opt-in solution and it is supported for Zabbix server. The native HA solution is designed to be simple in use, it will work across sites and does not have specific requirements for the databases that Zabbix recognizes. Users are free to use the native Zabbix HA solution, or a third-party HA solution, depending on what best suits the high availability requirements in their environment.

The solution consists of multiple `zabbix_server` instances or nodes. Every node:

- is configured separately
- uses the same database
- may have several modes: active, standby, unavailable, stopped

Only one node can be active (working) at a time. A standby node runs only one process - the HA manager. A standby node does no data collection, processing or other regular server activities; they do not listen on ports; they have minimum database connections.

Both active and standby nodes update their last access time every 5 seconds. Each standby node monitors the last access time of the active node. If the last access time of the active node is over 'failover delay' seconds, the standby node switches itself to be the active node and assigns 'unavailable' status to the previously active node.

The active node monitors its own database connectivity - if it is lost for more than `failover delay-5` seconds, it must stop all processing and switch to standby mode. The active node also monitors the status of the standby nodes - if the last access time of a standby node is over 'failover delay' seconds, the standby node is assigned the 'unavailable' status.

The nodes are designed to be compatible across minor Zabbix versions.

2 Agent

Overview

Zabbix agent is deployed on a monitoring target to actively monitor local resources and applications (hard drives, memory, processor statistics, etc.).

The agent gathers operational information locally and reports data to Zabbix server for further processing. In case of failures (such as a hard disk running full or a crashed service process), Zabbix server can actively alert the administrators of the particular machine that reported the failure.

Zabbix agents are highly efficient because of the use of native system calls for gathering statistical information.

Passive and active checks

Zabbix agents can perform passive and active checks:

- **Passive checks** - Zabbix agent responds to a request from Zabbix server (or proxy). For example, the server requests data (e.g., CPU load), and the agent returns the result.
- **Active checks** - Zabbix agent collects and sends data without waiting for a request from Zabbix server (or proxy). First, it retrieves a list of monitoring items from server (CPU load, available memory, etc.), then collects the required data and periodically sends new values back to it.

The agent check type is configured by selecting the respective monitoring **item type**. Zabbix agent processes items of type "Zabbix agent" or "Zabbix agent (active)".

Supported platforms

For supported platforms, refer to the [Requirements](#) page.

Agent on UNIX-like systems

Zabbix agent on UNIX-like systems is run on the host being monitored.

Installation

Zabbix agent can be installed on Linux-based systems using one of the following methods:

- [Zabbix packages](#) - select the Agent component (after selecting your Zabbix version, OS distribution, and OS version) and follow the provided instructions.
- [Zabbix sources](#) - download the source files and compile Zabbix agent by **configuring the sources** with the `--enable-agent` option.

Attention:

In general, 32-bit Zabbix agents will work on 64-bit systems, but may fail in some cases.

Note:

Pre-compiled Zabbix agent binaries are available for [download](#) for macOS, IBM AIX, FreeBSD, OpenBSD, and Solaris. Legacy binaries, compatible with current Zabbix server/proxy version, are available for [NetBSD](#) and [HP-UX](#).

If installed as package

Zabbix agent runs as a daemon process. The agent can be started by executing:

```
systemctl start zabbix-agent
```

This will work on most of GNU/Linux systems. On other systems you may need to run:

```
/etc/init.d/zabbix-agent start
```

To stop, restart, or check the status of Zabbix agent, use the following commands:

```
systemctl stop zabbix-agent
systemctl restart zabbix-agent
systemctl status zabbix-agent
```

Start up manually

You can start Zabbix agent by locating the `zabbix_agentd` binary and running it directly; for example:

```
zabbix_agentd
```

Agent on Windows systems

Zabbix agent on Windows runs as a Windows service.

Installation

Zabbix agent can be installed on Windows using one of the following methods:

- [Pre-compiled Zabbix agent binaries](#) - download the Zabbix agent MSI installer package and follow the instructions on the [Windows agent installation from MSI](#) page.
- [Zabbix sources](#) - download the source files and follow the instructions on the [Building Zabbix agent on Windows](#) page.

See the [Zabbix agent on Microsoft Windows](#) page for additional details on installing Zabbix agent (from a ZIP archive) as a Windows service.

Options

It is possible to run multiple instances of the agent on a host. A single instance can use the default configuration file or a configuration file specified in the command line. In case of multiple instances each agent instance must have its own configuration file (one of the instances can use the default configuration file).

The following command-line parameters can be used with Zabbix agent:

| Parameter | Description |
|-------------------------------|--|
| UNIX and Windows agent | |
| -c --config <config-file> | Path to the configuration file. You may use this option to specify a configuration file that is not the default one. On UNIX, default is /usr/local/etc/zabbix_agentd.conf or as set by compile-time variables --sysconfdir or --prefix On Windows, default is C:\Program Files\Zabbix Agent\zabbix_agentd.conf |
| -f --foreground | Run Zabbix agent in foreground (default: true). |
| -p --print | Print known items and exit. Note: To return user parameter results as well, you must specify the configuration file (if it is not in the default location). |
| -t --test <item key> | Test specified item and exit. Note: To return user parameter results as well, you must specify the configuration file (if it is not in the default location). |
| -T --test-config | Validate configuration file and exit. |
| -h --help | Display help information. |
| -V --version | Display version number. |
| UNIX agent only | |
| -R --runtime-control <option> | Perform administrative functions. See runtime control . |
| Windows agent only | |
| -m --multiple-agents | Use multiple agent instances (with -i, -d, -s, -x options). To distinguish service names of instances, each service name will include the Hostname value from the specified configuration file. |
| -S --startup-type <value> | Set the startup type of the Zabbix Windows agent service. Allowed values: automatic - (default) start the service automatically at Windows startup; delayed - delay starting the service after the automatically started services have completed startup (available on Windows Server 2008/Vista and later versions); manual - start the service manually (by a user or application); disabled - disable the service, so that it cannot be started by a user or application. You may use this option together with the -i option, or separately to modify the startup type of an already installed service. |
| -i --install | Install Zabbix Windows agent as service. |
| -d --uninstall | Uninstall Zabbix Windows agent service. |
| -s --start | Start Zabbix Windows agent service. |
| -x --stop | Stop Zabbix Windows agent service. |

Specific **examples** of using command-line parameters:

- printing all built-in agent items with values
- testing a user parameter with "mysql.ping" key defined in the specified configuration file
- installing a "Zabbix Agent" service for Windows using the default path to configuration file C:\Program Files\Zabbix Agent\zabbix_agentd.conf
- installing a "Zabbix Agent [Hostname]" service for Windows using the configuration file zabbix_agentd.conf located in the same folder as agent executable and making the service name unique by extending it by Hostname value from the config file
- modifying the startup type of an installed "Zabbix Agent" service for Windows using the configuration file zabbix_agentd.conf located in the same folder as agent executable

```
zabbix_agentd --print
zabbix_agentd -t "mysql.ping" -c /etc/zabbix/zabbix_agentd.conf
zabbix_agentd.exe -i
zabbix_agentd.exe -i -m -c zabbix_agentd.conf
zabbix_agentd.exe -c zabbix_agentd.conf -S delayed
```

Runtime control

With runtime control options you may change the log level of agent processes.

| Option | Description | Target |
|--|---|---|
| <code>log_level_increase[=target]</code> | Increases log level. If target is not specified, all processes are affected. | Target can be specified as: process type - all processes of specified type (e.g., listener) See all agent process types . process type,N - process type and number (e.g., listener,3) pid - process identifier (1 to 65535). For larger values specify target as 'process-type,N'. |
| <code>log_level_decrease[=target]</code> | Decreases log level. If target is not specified, all processes are affected. | |
| <code>userparameter_reload</code> | Reload values of the <i>UserParameter</i> and <i>Include</i> options from the current configuration file. | |

Examples:

- increasing log level of all processes
- increasing log level of the third listener process
- increasing log level of process with PID 1234
- decreasing log level of all active check processes

```
zabbix_agentd -R log_level_increase
zabbix_agentd -R log_level_increase=listener,3
zabbix_agentd -R log_level_increase=1234
zabbix_agentd -R log_level_decrease="active checks"
```

Note:

Runtime control is not supported on OpenBSD, NetBSD and Windows.

Agent process types

- `active checks` - process for performing active checks
- `collector` - process for data collection
- `listener` - process for listening to passive checks

The agent log file can be used to observe these process types.

Process user

Zabbix agent on UNIX is designed to run as a non-root user. It will run as whatever non-root user it is started as. So you can run agent as any non-root user without any issues.

If you will try to run it as 'root', it will switch to a hardcoded 'zabbix' user, which must be present on your system. You can only run agent as 'root' if you modify the 'AllowRoot' parameter in the agent configuration file accordingly.

Configuration file

For details on configuring Zabbix agent see the configuration file options for [zabbix_agentd](#) or [Windows agent](#).

Locale

Note that the agent requires a UTF-8 locale so that some textual agent items can return the expected content. Most modern Unix-like systems have a UTF-8 locale as default, however, there are some systems where that may need to be set specifically.

Exit code

Zabbix agent returns 0 in case of successful exit and 1 in case of failure.

3 Agent 2

Overview

Zabbix agent 2 is a new generation of [Zabbix agent](#), written in Go (with some C code reused from Zabbix agent). It is designed to:

- Reduce the number of TCP connections.
- Provide improved **concurrency of checks**.
- Be easily extendable with **plugins**, which provide simple checks with minimal code and support complex checks consisting of long-running scripts and standalone data gathering with periodic reporting.
- Function as a replacement for Zabbix agent, supporting all previous features.

Passive and active checks

Zabbix agent 2 supports **passive and active checks**, similarly to Zabbix agent. Additionally, Zabbix agent 2 active checks support **flexible/scheduling intervals** and **check concurrency** within one active server.

Note:

By default, after a restart, Zabbix agent 2 will schedule the first data collection for active checks at a conditionally random time within the item's update interval to prevent spikes in resource usage. To perform active checks that do not have **Scheduling update interval** immediately after the agent restart, set `ForceActiveChecksOnStart` parameter (global-level) or `Plugins.<Plugin name>.System.ForceActiveChecksOnStart` (affects only specific plugin checks) in the **configuration file**. Plugin-level parameter, if set, will override the global parameter.

Check concurrency

Checks from different plugins can be executed concurrently. The number of concurrent checks within one plugin is limited by the plugin capacity setting. Each plugin may have a hardcoded capacity setting (1000 being default) that can be lowered using the `Plugins.<PluginName>.System.Capacity=N` setting in the *Plugins* configuration **parameter**.

Supported platforms

For supported platforms, refer to the **Requirements** page.

Agent 2 on UNIX-like systems

Zabbix agent 2 on UNIX-like systems is run on the host being monitored.

Installation

Zabbix agent 2 can be installed on Linux-based systems using one of the following methods:

- **Zabbix packages** - select the Agent 2 component (after selecting your Zabbix version, OS distribution, and OS version) and follow the provided instructions.
- **Zabbix sources** - download the source files and compile Zabbix agent by **configuring the sources** with the `--enable-agent2` option. Note that a configured Go environment with a currently **supported Go version** is required for building Zabbix agent 2.

If installed as package

Zabbix agent 2 runs as a foreground process and relies on an external service manager (e.g., systemd) for background execution; Zabbix agent 2 does not have built-in daemonization support on Linux.

The agent can be started by executing:

```
systemctl start zabbix-agent2
```

To stop, restart, or check the status of Zabbix agent 2, use the following commands:

```
systemctl stop zabbix-agent2
systemctl restart zabbix-agent2
systemctl status zabbix-agent2
```

Start up manually

You can start Zabbix agent by locating the `zabbix_agent2` binary and running it directly; for example:

```
zabbix_agent2
```

Agent 2 on Windows systems

Zabbix agent 2 runs as a standalone process; however, it can also be run as a Windows service.

Installation

Zabbix agent 2 can be installed on Windows using one of the following methods:

- **Pre-compiled Zabbix agent binaries** - download the Zabbix agent MSI installer package and follow the instructions on the **Windows agent installation from MSI** page.
- **Zabbix sources** - download the source files and follow the instructions on the **Building Zabbix agent 2 on Windows** page. Note that a configured Go environment with a currently **supported Go version** is required for building Zabbix agent 2.

Note:

Zabbix agent 2 monitoring capabilities can be extended with plugins. While **built-in plugins** are available out-of-the-box, **loadable plugins** on Windows must be installed separately. For more information, see [Zabbix agent 2 loadable plugins](#).

See the [Zabbix agent on Microsoft Windows](#) page for additional details on installing Zabbix agent 2 (from a ZIP archive) as a Windows service.

Options

The following command-line parameters can be used with Zabbix agent 2:

| Parameter | Description |
|-------------------------------|--|
| UNIX and Windows agent | |
| -c --config <config-file> | Path to the configuration file. You may use this option to specify a configuration file that is not the default one. On UNIX, default is /usr/local/etc/zabbix_agent2.conf or as set by compile-time variables --sysconfdir or --prefix On Windows, default is C:\Program Files\Zabbix Agent 2\zabbix_agent2.conf |
| -f --foreground | Run Zabbix agent in foreground (default: true). |
| -p --print | Print known items and exit. Note: To return user parameter results as well, you must specify the configuration file (if it is not in the default location). |
| -t --test <item key> | Test specified item and exit. Note: To return user parameter results as well, you must specify the configuration file (if it is not in the default location). |
| -T --test-config | Validate configuration file and exit. |
| -h --help | Print help information and exit. |
| -v --verbose | Print debugging information. Use this option with -p and -t options. |
| -V --version | Print agent version and license information. |
| -R --runtime-control <option> | Perform administrative functions. See runtime control . |
| Windows agent only | |
| -m --multiple-agents | Use multiple agent instances (with -i, -d, -s, -x options). To distinguish service names of instances, each service name will include the Hostname value from the specified configuration file. |
| -S --startup-type <value> | Set the startup type of the Zabbix Windows agent service. Allowed values: automatic - (default) start the service automatically at Windows startup; delayed - delay starting the service after the automatically started services have completed startup; manual - start the service manually (by a user or application); disabled - disable the service, so that it cannot be started by a user or application. You may use this option together with the -i option, or separately to modify the startup type of an already installed service. |
| -i --install | Install Zabbix Windows agent as service. |
| -d --uninstall | Uninstall Zabbix Windows agent service. |
| -s --start | Start Zabbix Windows agent service. |
| -x --stop | Stop Zabbix Windows agent service. |

Specific **examples** of using command-line parameters:

- print all built-in agent items with values
- test a user parameter with "mysql.ping" key defined in the specified configuration file
- installing a "Zabbix Agent" service for Windows using the default path to configuration file C:\Program Files\Zabbix Agent 2\zabbix_agent2.conf
- modifying the startup type of an installed "Zabbix Agent" service for Windows using the configuration file zabbix_agent2.conf located in the same folder as agent executable

```
zabbix_agent2 --print
zabbix_agent2 -t "mysql.ping" -c /etc/zabbix/zabbix_agentd.conf
zabbix_agent2.exe -i
zabbix_agent2.exe -c zabbix_agent2.conf -S delayed
```

Runtime control

Runtime control provides some options for remote control.

| Option | Description |
|----------------------|---|
| log_level_increase | Increase log level. |
| log_level_decrease | Decrease log level. |
| metrics | List available metrics. |
| version | Display agent version. |
| userparameter_reload | Reload values of the <i>UserParameter</i> and <i>Include</i> options from the current configuration file. |
| help | Display help information on runtime control. |

Examples:

- increasing log level for agent 2
- print runtime control options

```
zabbix_agent2 -R log_level_increase
zabbix_agent2 -R help
```

Configuration file

The configuration parameters of agent 2 are mostly compatible with Zabbix agent with some exceptions.

| New parameters | Description |
|---|---|
| <i>ControlSocket</i> | The runtime control socket path. Agent 2 uses a control socket for runtime commands . |
| <i>EnablePersistentBuffer</i> , <i>PersistentBufferFile</i> , <i>PersistentBufferPeriod</i> | These parameters are used to configure persistent storage on agent 2 for active items. |
| <i>ForceActiveChecksOnStart</i> | Determines whether the agent should perform active checks immediately after restart or spread evenly over time. |
| <i>Plugins</i> | Plugins may have their own parameters, in the format <code>Plugins.<Plugin name>.<Parameter>=<value></code> . A common plugin parameter is <i>System.Capacity</i> , setting the limit of checks that can be executed at the same time. |
| <i>StatusPort</i> | The port agent 2 will be listening on for HTTP status request and display of a list of configured plugins and some internal parameters |
| Dropped parameters | Description |
| <i>AllowRoot</i> , <i>User</i> | Not supported because daemonization is not supported. |
| <i>LoadModule</i> , <i>LoadModulePath</i> | Loadable modules are not supported. |
| <i>StartAgents</i> | This parameter was used in Zabbix agent to increase passive check concurrency or disable them. In Agent 2, the concurrency is configured at a plugin level and can be limited by a capacity setting. Whereas disabling passive checks is not currently supported. |
| <i>HostInterface</i> , <i>HostInterfaceItem</i> | Not yet supported. |

For more details see the configuration file options for **zabbix_agent2**.

Exit codes

Zabbix agent 2 can also be compiled with older OpenSSL versions (1.0.1, 1.0.2).

In this case Zabbix provides mutexes for locking in OpenSSL. If a mutex lock or unlock fails then an error message is printed to the standard error stream (STDERR) and Agent 2 exits with return code 2 or 3, respectively.

4 Proxy

Overview

Zabbix proxy is a process that may collect monitoring data from one or more monitored devices and send the information to the Zabbix server, essentially working on behalf of the server. All collected data is buffered locally and then transferred to the Zabbix server the proxy belongs to.

Deploying a proxy is optional, but may be very beneficial to distribute the load of a single Zabbix server. If only proxies collect data, processing on the server becomes less CPU and disk I/O hungry.

A Zabbix proxy is the ideal solution for centralized monitoring of remote locations, branches and networks with no local administrators.

Zabbix proxy requires a separate database.

Attention:
Note that databases supported with Zabbix proxy are SQLite, MySQL and PostgreSQL.

See also: [Using proxies in a distributed environment](#)

Running proxy

If installed as package

Zabbix proxy runs as a daemon process. The proxy can be started by executing:

```
systemctl start zabbix-proxy
```

This will work on most of GNU/Linux systems. On other systems you may need to run:

```
/etc/init.d/zabbix-proxy start
```

Similarly, for stopping/restarting/viewing status of Zabbix proxy, use the following commands:

```
systemctl stop zabbix-proxy
systemctl restart zabbix-proxy
systemctl status zabbix-proxy
```

Start up manually

If the above does not work you have to start it manually. Find the path to the zabbix_proxy binary and execute:

```
zabbix_proxy
```

You can use the following command-line parameters with Zabbix proxy:

```
-c --config <file>          path to the configuration file
-f --foreground              run Zabbix proxy in foreground
-R --runtime-control <option> perform administrative functions
-T --test-config             validate configuration file and exit
-h --help                   give this help
-V --version                 display version number
```

Examples of running Zabbix proxy with command-line parameters:

```
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf
zabbix_proxy --help
zabbix_proxy -V
```

Runtime control

Runtime control options:

| Option | Description | Target |
|----------------------|--|--|
| config_cache_reload | Reload configuration cache. Ignored if cache is being currently loaded. Active Zabbix proxy will connect to the Zabbix server and request configuration data. Passive Zabbix proxy will request configuration data from Zabbix server the next time when the server connects to the proxy. | |
| diaginfo[=<section>] | Get other diagnostic information in the proxy log file. | historycache - history cache statistics preprocessing - preprocessing manager statistics locks - list of mutexes (is empty on <i>BSD</i> systems) |
| snmp_cache_reload | Reload SNMP cache, clear the SNMP properties (engine time, engine boots, engine id, credentials) for all hosts. | |

| Option | Description | Target |
|-------------------------------|---|--|
| housekeeper_execute | Start the housekeeping procedure. Ignored if the housekeeping procedure is currently in progress. | |
| log_level_increase[=<target>] | Change log level, affects all processes if target is not specified. Not supported on <i>BSD</i> systems. | process type - All processes of specified type (e.g., poller) See all proxy process types . process type,N - Process type and number (e.g., poller,3) pid - Process identifier (1 to 65535). For larger values specify target as 'process type,N'. |
| log_level_decrease[=<target>] | Decrease log level, affects all processes if target is not specified. Not supported on <i>BSD</i> systems. | |
| prof_enable[=<target>] | Enable profiling. Affects all processes if target is not specified. Enabled profiling provides details of all rwlocks/mutexes by function name. | process type - All processes of specified type (e.g., history syncer) See all proxy process types . process type,N - Process type and number (e.g., history syncer,1) pid - Process identifier (1 to 65535). For larger values specify target as 'process type,N'. scope - rwlock, mutex, processing can be used with the process type and number (e.g., history syncer,1,processing) or all processes of type (e.g., history syncer,rwlock) |
| prof_disable[=<target>] | Disable profiling. Affects all processes if target is not specified. | process type - All processes of specified type (e.g., history syncer) See all proxy process types . process type,N - Process type and number (e.g., history syncer,1) pid - Process identifier (1 to 65535). For larger values specify target as 'process type,N'. |

Example of using runtime control to reload the proxy configuration cache:

```
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf -R config_cache_reload
```

Examples of using runtime control to gather diagnostic information:

```
# Gather all available diagnostic information in the proxy log file:
zabbix_proxy -R diaginfo
```

```
# Gather history cache statistics in the proxy log file:
zabbix_proxy -R diaginfo=historycache
```

Example of using runtime control to reload the SNMP cache:

```
zabbix_proxy -R snmp_cache_reload
```

Example of using runtime control to trigger execution of housekeeper

```
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf -R housekeeper_execute
```

Examples of using runtime control to change log level:

```
# Increase log level of all processes:
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf -R log_level_increase
```

```
# Increase log level of second poller process:
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf -R log_level_increase=poller,2
```

```
# Increase log level of process with PID 1234:
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf -R log_level_increase=1234
```

```
# Decrease log level of all http poller processes:
zabbix_proxy -c /usr/local/etc/zabbix_proxy.conf -R log_level_decrease="http poller"
```

Process user

Zabbix proxy is designed to run as a non-root user. It will run as whatever non-root user it is started as. So you can run proxy as any non-root user without any issues.

If you will try to run it as 'root', it will switch to a hardcoded 'zabbix' user, which must be present on your system. You can only run proxy as 'root' if you modify the 'AllowRoot' parameter in the proxy configuration file accordingly.

Configuration file

See the [configuration file](#) options for details on configuring zabbix_proxy.

Proxy process types and threads

- `agent poller` - asynchronous poller process for passive checks with a worker thread
- `availability manager` - process for host availability updates
- `browser poller` - poller for browser item checks
- `configuration syncer` - process for managing in-memory cache of configuration data
- `data sender` - proxy data sender
- `discovery manager` - manager process for discovery of devices
- `discovery worker` - process for handling discovery tasks from the discovery manager
- `history syncer` - history DB writer
- `housekeeper` - process for removal of old historical data
- `http agent poller` - asynchronous poller process for HTTP checks with a worker thread
- `http poller` - web monitoring poller
- `icmp pinger` - poller for icmping checks
- `internal poller` - poller for internal checks
- `ipmi manager` - IPMI poller manager
- `ipmi poller` - poller for IPMI checks
- `java poller` - poller for Java checks
- `odbc poller` - poller for ODBC checks
- `poller` - normal poller for passive checks
- `preprocessing manager` - manager of preprocessing tasks with preprocessing worker threads
- `preprocessing worker` - thread for data preprocessing
- `self-monitoring` - process for collecting internal server statistics
- `snmp poller` - asynchronous poller process for SNMP checks with a worker thread (`walk[OID]` and `get[OID]` items only)
- `snmp trapper` - trapper for SNMP traps
- `task manager` - process for remote execution of tasks requested by other components (e.g. close problem, acknowledge problem, check item value now, remote command functionality)
- `trapper` - trapper for active checks, traps, proxy communication
- `unreachable poller` - poller for unreachable devices
- `vmware collector` - VMware data collector responsible for data gathering from VMware services

The proxy log file can be used to observe these process types.

Various types of Zabbix proxy processes can be monitored using the **zabbix[process,<type>,<mode>,<state>]** internal [item](#).

Supported platforms

Zabbix proxy runs on the same list of [supported platforms](#) as Zabbix server.

Memory buffer

The memory buffer allows to store new data (item values, network discovery, host autoregistration) in the buffer and upload to Zabbix server without accessing the database. The memory buffer has been introduced for the proxy since Zabbix 7.0.

In installations before Zabbix 7.0 the collected data was stored in the database before uploading to Zabbix server. For these installations this remains the default behavior after upgrading to Zabbix 7.0.

For optimized performance, it is recommended to configure the use of memory buffer on the proxy. This is possible by modifying the value of **ProxyBufferMode** from "disk" (hardcoded default for existing installations) to "hybrid" (recommended) or "memory". It is also required to set the memory buffer size (**ProxyMemoryBufferSize** parameter).

In hybrid mode the buffer is protected from data loss by flushing unsent data to the database if the proxy is stopped, the buffer is full or data too old. When all values have been flushed into database, the proxy goes back to using memory buffer.

In memory mode, the memory buffer will be used, however, there is no protection against data loss. If the proxy is stopped, or the memory gets overfilled, the unsent data will be dropped.

The hybrid mode (**ProxyBufferMode=hybrid**) is applied to all new installations since Zabbix 7.0.

Additional parameters such as [ProxyMemoryBufferSize](#) and [ProxyMemoryBufferAge](#) define the memory buffer size and the maximum age of data in the buffer, respectively.

Note that with conflicting configuration the proxy will print an error and fail to start, for example, if:

- ProxyBufferMode is set to "hybrid" or "memory" and ProxyMemoryBufferSize is "0";
- ProxyBufferMode is set to "hybrid" or "memory" and ProxyLocalBuffer is not "0".

Locale

Note that the proxy requires a UTF-8 locale so that some textual items can be interpreted correctly. Most modern Unix-like systems have a UTF-8 locale as default, however, there are some systems where that may need to be set specifically.

Calculation of queues during maintenance

Attention:

The Zabbix proxy is not aware of maintenance periods; see [Calculation of queues during maintenance](#) for details.

5 Java gateway

Overview

Native support for monitoring JMX applications exists in the form of a Zabbix daemon called "Zabbix Java gateway". Zabbix Java gateway is a daemon written in Java. To find out the value of a particular JMX counter on a host, Zabbix server queries Zabbix Java gateway, which uses the [JMX management API](#) to query the application of interest remotely. The application does not need any additional software installed, it just has to be started with `-Dcom.sun.management.jmxremote` option on the command line.

Java gateway accepts incoming connection from Zabbix server or proxy and can only be used as a "passive proxy". As opposed to Zabbix proxy, it may also be used from Zabbix proxy (Zabbix proxies cannot be chained). Access to each Java gateway is configured directly in Zabbix server or proxy configuration file, thus only one Java gateway may be configured per Zabbix server or Zabbix proxy. If a host will have items of type **JMX agent** and items of other type, only the **JMX agent** items will be passed to Java gateway for retrieval.

When an item has to be updated over Java gateway, Zabbix server or proxy will connect to the Java gateway and request the value, which Java gateway in turn retrieves and passes back to the server or proxy. As such, Java gateway does not cache any values.

Zabbix server or proxy has a specific type of processes that connect to Java gateway, controlled by the option **StartJavaPollers**. Internally, Java gateway starts multiple threads, controlled by the **START_POLLERS** option. On the server side, if a connection takes more than **Timeout** seconds, it will be terminated, but Java gateway might still be busy retrieving value from the JMX counter. To solve this, there is the **TIMEOUT** option in Java gateway that allows to set timeout for JMX network operations.

Zabbix server or proxy will try to pool requests to a single JMX target together as much as possible (affected by item intervals) and send them to the Java gateway in a single connection for better performance.

It is suggested to have **StartJavaPollers** less than or equal to **START_POLLERS**, otherwise there might be situations when no threads are available in the Java gateway to service incoming requests; in such a case Java gateway uses `ThreadPoolExecutor.CallerRunsPolicy`, meaning that the main thread will service the incoming request and will not accept any new requests temporarily.

If you are trying to monitor Wildfly-based Java applications with Zabbix Java gateway, please install the latest `jboss-client.jar` available on the [Wildfly download page](#).

Getting Java gateway

You can install Java gateway either from the sources or packages downloaded from [Zabbix website](#).

Using the links below you can access information how to get and run Zabbix Java gateway, how to configure Zabbix server (or Zabbix proxy) to use Zabbix Java gateway for JMX monitoring, and how to configure Zabbix items in Zabbix frontend that correspond to particular JMX counters.

| Installation from | Instructions | Instructions |
|-------------------------------|------------------------------|-----------------------|
| <i>Sources</i> | Installation | Setup |
| <i>RHEL packages</i> | Installation | Setup |
| <i>Debian/Ubuntu packages</i> | Installation | Setup |

1 Setup from sources

Overview

If **installed** from sources, the following information will help you in setting up Zabbix **Java gateway**.

Overview of files

If you obtained Java gateway from sources, you should have ended up with a collection of shell scripts, JAR and configuration files under \$PREFIX/sbin/zabbix_java. The role of these files is summarized below.

bin/zabbix-java-gateway-\$VERSION.jar

Java gateway JAR file itself.

lib/logback-core-1.5.16.jar

lib/logback-classic-1.5.16.jar

lib/slf4j-api-2.0.16.jar

lib/android-json-4.3_r3.1.jar

Dependencies of Java gateway: [Logback](#), [SLF4J](#), and [Android JSON](#) library.

lib/logback.xml

lib/logback-console.xml

Configuration files for Logback.

shutdown.sh

startup.sh

Convenience scripts for starting and stopping Java gateway.

settings.sh

Configuration file that is sourced by startup and shutdown scripts above.

Configuring and running Java gateway

By default, Java gateway listens on port 10052. If you plan on running Java gateway on a different port, you can specify that in settings.sh script. See the description of [Java gateway configuration file](#) for how to specify this and other options.

Warning:

Port 10052 is not [IANA registered](#).

Once you are comfortable with the settings, you can start Java gateway by running the startup script:

```
./startup.sh
```

Likewise, once you no longer need Java gateway, run the shutdown script to stop it:

```
./shutdown.sh
```

Note that unlike server or proxy, Java gateway is lightweight and does not need a database.

Configuring server for use with Java gateway

With Java gateway up and running, you have to tell Zabbix server where to find Zabbix Java gateway. This is done by specifying JavaGateway and JavaGatewayPort parameters in the [server configuration file](#). If the host on which JMX application is running is monitored by Zabbix proxy, then you specify the connection parameters in the [proxy configuration file](#) instead.

```
JavaGateway=192.168.3.14
```

```
JavaGatewayPort=10052
```

By default, server does not start any processes related to JMX monitoring. If you wish to use it, however, you have to specify the number of pre-forked instances of Java pollers. You do this in the same way you specify regular pollers and trappers.

```
StartJavaPollers=5
```

Do not forget to restart server or proxy, once you are done with configuring them.

Debugging Java gateway

In case there are any problems with Java gateway or an error message that you see about an item in the frontend is not descriptive enough, you might wish to take a look at Java gateway log file.

By default, Java gateway logs its activities into /tmp/zabbix_java.log file with log level "info". Sometimes that information is not enough and there is a need for information at log level "debug". In order to increase logging level, modify file lib/logback.xml and change the level attribute of <root> tag to "debug":

```
<root level="debug">
  <appender-ref ref="FILE" />
</root>
```

Note that unlike Zabbix server or Zabbix proxy, there is no need to restart Zabbix Java gateway after changing logback.xml file - changes in logback.xml will be picked up automatically. When you are done with debugging, you can return the logging level to "info".

If you wish to log to a different file or a completely different medium like database, adjust logback.xml file to meet your needs. See [Logback Manual](#) for more details.

Sometimes for debugging purposes it is useful to start Java gateway as a console application rather than a daemon. To do that, comment out PID_FILE variable in settings.sh. If PID_FILE is omitted, startup.sh script starts Java gateway as a console application and makes Logback use lib/logback-console.xml file instead, which not only logs to console, but has logging level "debug" enabled as well.

Finally, note that since Java gateway uses SLF4J for logging, you can replace Logback with the framework of your choice by placing an appropriate JAR file in lib directory. See [SLF4J Manual](#) for more details.

JMX monitoring

See [JMX monitoring](#) page for more details.

2 Setup from RHEL packages

Overview

If [installed](#) from RHEL packages, the following information will help you in setting up Zabbix [Java gateway](#).

Configuring and running Java gateway

Configuration parameters of Zabbix Java gateway may be tuned in the file:

```
/etc/zabbix/zabbix_java_gateway.conf
```

For more details, see Zabbix Java gateway configuration [parameters](#).

To start Zabbix Java gateway:

```
systemctl restart zabbix-java-gateway
```

To automatically start Zabbix Java gateway on boot:

RHEL 7 and later:

```
systemctl enable zabbix-java-gateway
```

RHEL prior to 7:

```
chkconfig --level 12345 zabbix-java-gateway on
```

Configuring server for use with Java gateway

With Java gateway up and running, you have to tell Zabbix server where to find Zabbix Java gateway. This is done by specifying JavaGateway and JavaGatewayPort parameters in the [server configuration file](#). If the host on which JMX application is running is monitored by Zabbix proxy, then you specify the connection parameters in the [proxy configuration file](#) instead.

```
JavaGateway=192.168.3.14
```

```
JavaGatewayPort=10052
```

By default, server does not start any processes related to JMX monitoring. If you wish to use it, however, you have to specify the number of pre-forked instances of Java pollers. You do this in the same way you specify regular pollers and trappers.

```
StartJavaPollers=5
```

Do not forget to restart server or proxy, once you are done with configuring them.

Debugging Java gateway

Zabbix Java gateway log file is:

```
/var/log/zabbix/zabbix_java_gateway.log
```

If you like to increase the logging, edit the file:

/etc/zabbix/zabbix_java_gateway_logback.xml

and change level="info" to "debug" or even "trace" (for deep troubleshooting):

```
<configuration scan="true" scanPeriod="15 seconds">
[...]  
    <root level="info">  
        <appender-ref ref="FILE" />  
    </root>  
  
</configuration>
```

JMX monitoring

See [JMX monitoring](#) page for more details.

3 Setup from Debian/Ubuntu packages

Overview

If **installed** from Debian/Ubuntu packages, the following information will help you in setting up Zabbix **Java gateway**.

Configuring and running Java gateway

Java gateway configuration may be tuned in the file:

/etc/zabbix/zabbix_java_gateway.conf

For more details, see Zabbix Java gateway configuration [parameters](#).

To start Zabbix Java gateway:

```
systemctl restart zabbix-java-gateway
```

To automatically start Zabbix Java gateway on boot:

```
systemctl enable zabbix-java-gateway
```

Configuring server for use with Java gateway

With Java gateway up and running, you have to tell Zabbix server where to find Zabbix Java gateway. This is done by specifying JavaGateway and JavaGatewayPort parameters in the [server configuration file](#). If the host on which JMX application is running is monitored by Zabbix proxy, then you specify the connection parameters in the [proxy configuration file](#) instead.

```
JavaGateway=192.168.3.14
```

```
JavaGatewayPort=10052
```

By default, server does not start any processes related to JMX monitoring. If you wish to use it, however, you have to specify the number of pre-forked instances of Java pollers. You do this in the same way you specify regular pollers and trappers.

```
StartJavaPollers=5
```

Do not forget to restart server or proxy, once you are done with configuring them.

Debugging Java gateway

Zabbix Java gateway log file is:

/var/log/zabbix/zabbix_java_gateway.log

If you like to increase the logging, edit the file:

/etc/zabbix/zabbix_java_gateway_logback.xml

and change level="info" to "debug" or even "trace" (for deep troubleshooting):

```
<configuration scan="true" scanPeriod="15 seconds">
[...]  
    <root level="info">  
        <appender-ref ref="FILE" />  
    </root>  
  
</configuration>
```

JMX monitoring

See [JMX monitoring](#) page for more details.

6 Sender

Overview

Zabbix sender is a command line utility that may be used to send performance data to Zabbix server for processing.

The utility is usually used in long running user scripts for periodical sending of availability and performance data.

For sending results directly to Zabbix server or proxy, a [trapper item](#) type must be configured.

See also [zabbix_utils](#) - a Python library that has built-in functionality to act like Zabbix sender.

Running Zabbix sender

An example of running Zabbix UNIX sender:

```
cd bin
./zabbix_sender -z zabbix -s "Linux DB3" -k db.connections -o 43
```

where:

- `z` - Zabbix server host (IP address can be used as well)
- `s` - technical name of monitored host (as registered in Zabbix frontend)
- `k` - item key
- `o` - value to send

Attention:

Options that contain whitespaces, must be quoted using double quotes.

Zabbix sender can be used to send multiple values from an input file. See the [Zabbix sender manpage](#) for more information.

If a configuration file is specified, Zabbix sender uses all addresses defined in the agent `ServerActive` configuration parameter for sending data. If sending to one address fails, the sender tries sending to the other addresses. If sending of batch data fails to one address, the following batches are not sent to this address.

Zabbix sender accepts strings in UTF-8 encoding (for both UNIX-like systems and Windows) without byte order mark (BOM) first in the file.

Zabbix sender on Windows can be run similarly:

```
zabbix_sender.exe [options]
```

`zabbix_sender` realtime sending scenarios will gather multiple values passed to it in close succession and send them to the server in a single connection. A value that is not further apart from the previous value than 0.2 seconds can be put in the same stack, but maximum polling time still is 1 second.

Note:

Zabbix sender will terminate if invalid (not following *parameter=value* notation) parameter entry is present in the specified configuration file.

Running Zabbix sender with low-level discovery

An example of running Zabbix sender for sending a JSON-formatted value for low-level discovery:

```
./zabbix_sender -z 192.168.1.113 -s "Zabbix server" -k trapper.discovery.item -o '["{#FSNAME}":"/", "{#FSNAME}"]'
```

For this to work, the low-level discovery rule must have a Zabbix trapper item type (in this example, with `trapper.discovery.item` key).

7 Get

Overview

Zabbix get is a command-line utility, which can be used to communicate with Zabbix agent and retrieve required information from the agent.

The utility is usually used for the troubleshooting of Zabbix agents.

See also [zabbix_utils](#) - a Python library that has built-in functionality to act like Zabbix get.

Running Zabbix get

An example of running Zabbix get under UNIX to get the processor load value from the agent:

```
cd bin
./zabbix_get -s 127.0.0.1 -p 10050 -k system.cpu.load[all,avg1]
```

Another example of running Zabbix get for capturing a string from a website:

```
cd bin
./zabbix_get -s 192.168.1.1 -p 10050 -k "web.page.regex[www.example.com,,,\"USA: ([a-zA-Z0-9.-]+)\",,\\1]"
```

Note that the item key here contains a space so quotes are used to mark the item key to the shell. The quotes are not part of the item key; they will be trimmed by the shell and will not be passed to Zabbix agent.

If an item key is unsupported Zabbix get will return the exit code 1.

Zabbix get accepts the following command line parameters:

| | |
|--|---|
| <code>-s --host <host name or IP></code> | Specify host name or IP address of a host |
| <code>-p --port <port number></code> | Specify port number of agent running on the host (default: 10050) |
| <code>-I --source-address <IP address></code> | Specify source IP address |
| <code>-t --timeout <seconds></code> | Specify timeout. Valid range: 1-30 seconds (default: 30 seconds) |
| <code>-k --key <item key></code> | Specify key of item to retrieve value for |
| <code>-P --protocol <value></code> | Protocol used to communicate with agent. Values: auto - connect using JSON protocol, fallback and retry with plaintext json - connect using JSON protocol plaintext - connect using plaintext protocol where just item key is used |
| <code>-h --help</code> | Display this help message |
| <code>-V --version</code> | Display version number |
| <code>--tls-connect <value></code> | How to connect to agent. Values: unencrypted - connect without encryption (default) psk - connect using TLS and a pre-shared key cert - connect using TLS and a certificate |
| <code>--tls-ca-file <CA file></code> | Full pathname of a file containing the top-level CA(s) certificate |
| <code>--tls-crl-file <CRL file></code> | Full pathname of a file containing revoked certificates |
| <code>--tls-agent-cert-issuer <cert issuer></code> | Allowed agent certificate issuer |
| <code>--tls-agent-cert-subject <cert subject></code> | Allowed agent certificate subject |
| <code>--tls-cert-file <cert file></code> | Full pathname of a file containing the certificate or certificate chain |
| <code>--tls-key-file <key file></code> | Full pathname of a file containing the private key |
| <code>--tls-psk-identity <PSK-identity></code> | Unique, case sensitive string used to identify the pre-shared key |
| <code>--tls-psk-file <PSK-file></code> | Full pathname of a file containing the pre-shared key |
| <code>--tls-cipher13 <cipher-string></code> | Cipher string for OpenSSL 1.1.1 or newer for TLS 1.3. Override the default |
| <code>--tls-cipher <cipher-string></code> | GnuTLS priority string (for TLS 1.2 and up) or OpenSSL cipher string |

See also [Zabbix get manpage](#) for more information.

Zabbix get on Windows can be run similarly:

```
zabbix_get.exe [options]
```

8 JS

Overview

`zabbix_js` is a command line utility that can be used for embedded script testing.

This utility will execute a user script with a string parameter and print the result. Scripts are executed using the embedded Zabbix scripting engine.

In case of compilation or execution errors `zabbix_js` will print the error in stderr and exit with code 1.

Usage

```
zabbix_js -s script-file -p input-param [-l log-level] [-t timeout]
zabbix_js -s script-file -i input-file [-l log-level] [-t timeout]
zabbix_js -h
zabbix_js -V
```

zabbix_js accepts the following command line parameters:

| | |
|--------------------------|--|
| -s, --script script-file | Specify the file name of the script to execute. If '-' is specified as |
| -i, --input input-file | Specify the file name of the input parameter. If '-' is specified as f |
| -p, --param input-param | Specify the input parameter. |
| -l, --loglevel log-level | Specify the log level. |
| -t, --timeout timeout | Specify the timeout in seconds. Valid range: 1-60 seconds (default: 10 |
| -h, --help | Display help information. |
| -V, --version | Display the version number. |
| -w <webdriver url> | Enables browser monitoring. |

Example:

```
zabbix_js -s script-file.js -p example
```

9 Web service

Overview

Zabbix web service is a process that is used for communication with external web services. Currently, Zabbix web service is used for generating and sending **scheduled reports** with plans to add additional functionality in the future.

Zabbix server connects to the web service via HTTP(S). Zabbix web service requires **Google Chrome** to be installed on the same host; on some distributions the service may also work with Chromium (see **known issues**).

Installation

The official zabbix-web-service package is available in the [Zabbix repository](#).

To compile Zabbix web service **from sources**, specify the `--enable-webservice` configure option.

To configure Zabbix web service, update the `zabbix_web_service.conf` configuration file parameters.

Attention:

It is strongly recommended to set up encryption between Zabbix server and Zabbix web service **using certificates**. By default, data transmitted between Zabbix server and Zabbix web service is not encrypted, which can lead to unauthorized access.

4 Installation

Please use the sidebar to access content in the Installation section.

1 Getting Zabbix

Overview

There are four ways of getting Zabbix:

- Install it from the **distribution packages**
- Download the latest source archive and **compile it yourself**
- Install it from the **containers**
- Download the **virtual appliance**

To download the latest distribution packages, pre-compiled sources or the virtual appliance, go to the [Zabbix download page](#), where direct links to latest versions are provided.

Getting Zabbix source code

There are several ways of getting Zabbix source code:

- You can [download](#) the released stable versions from the official Zabbix website
- You can [download](#) nightly builds from the official Zabbix website developer page
- You can get the latest development version from the Git source code repository system:
 - The primary location of the full repository is at <https://git.zabbix.com/scm/zbx/zabbix.git>
 - Master and supported releases are also mirrored to Github at <https://github.com/zabbix/zabbix>

A Git client must be installed to clone the repository. The official commandline Git client package is commonly called **git** in distributions. To install, for example, on Debian/Ubuntu, run:

```
sudo apt-get update
sudo apt-get install git
```

To grab all Zabbix source, change to the directory you want to place the code in and execute:

```
git clone https://git.zabbix.com/scm/zbx/zabbix.git
```

2 Requirements

Hardware

Memory

Zabbix requires both physical and disk memory. The amount of required disk memory obviously depends on the number of hosts and parameters that are being monitored. If you're planning to keep a long history of monitored parameters, you should be thinking of at least a couple of gigabytes to have enough space to store the history in the database. Each Zabbix daemon process requires several connections to a database server. The amount of memory allocated for the connection depends on the configuration of the database engine.

Note:

The more physical memory you have, the faster the database (and therefore Zabbix) works.

CPU

Zabbix and especially Zabbix database may require significant CPU resources depending on number of monitored parameters and chosen database engine.

Other hardware

A serial communication port and a serial GSM modem are required for using SMS notification support in Zabbix. USB-to-serial converter will also work.

Examples of hardware configuration

The table provides examples of hardware configuration, assuming a **Linux/BSD/Unix** platform.

These are size and hardware configuration examples to start with. Each Zabbix installation is unique. Make sure to benchmark the performance of your Zabbix system in a staging or development environment, so that you can fully understand your requirements before deploying the Zabbix installation to its production environment.

| Installation size | Monitored metrics ¹ | CPU/vCPU cores | Memory (GiB) | Database | Amazon EC2 ² |
|-------------------|--------------------------------|----------------|--------------|---|-------------------------|
| Small | 1 000 | 2 | 8 | MySQL Server, Percona Server, MariaDB Server, PostgreSQL | m6i.large/m6g.large |
| Medium | 10 000 | 4 | 16 | MySQL Server, Percona Server, MariaDB Server, PostgreSQL | m6i.xlarge/m6g.xlarge |
| Large | 100 000 | 16 | 64 | MySQL Server, Percona Server, MariaDB Server, PostgreSQL | m6i.4xlarge/m6g.4xlarge |

| Installation size | Monitored metrics ¹ | CPU/vCPU cores | Memory (GiB) | Database | Amazon EC2 ² |
|-------------------|--------------------------------|----------------|--------------|---|-------------------------|
| Very large | 1 000 000 | 32 | 96 | MySQL Server, Percona Server, MariaDB Server, PostgreSQL | m6i.8xlarge/m6g.8xlarge |

¹ 1 metric = 1 item + 1 trigger + 1 graph
² Example with Amazon general purpose EC2 instances, using ARM64 or x86_64 architecture, a proper instance type like Compute/Memory/Storage optimised should be selected during Zabbix installation evaluation and testing before installing in its production environment.

Note:

Actual configuration depends on the number of active items and refresh rates very much (see [database size](#) section of this page for details). It is highly recommended to run the database on a separate server for large installations.

Supported platforms

Due to security requirements and the mission-critical nature of the monitoring server, UNIX is the only operating system that can consistently deliver the necessary performance, fault tolerance, and resilience. Zabbix operates on market-leading versions.

Zabbix components are available and tested for the following platforms:

| Platform | Server | Agent | Agent 2 | Comments |
|----------|--------|-------|---------|---|
| Linux | x | x | x | |
| Windows | - | x | x | Zabbix agent is supported on all desktop and server versions since Windows XP (64-bit)/Server 2003. |
| | | | | Zabbix agent 2 is supported on all desktop and server versions since Windows 10 (32-bit)/Server 2016, as it is compiled only with a supported Go version to prevent critical security vulnerabilities. Since Go 1.21, the minimum required Windows versions are raised, making Windows 10/Server 2016 the minimum version for Zabbix agent 2. |
| macOS | x | x | - | |
| IBM AIX | x | x | - | Zabbix agent does not work on AIX platforms below versions 6.1 TL07 / 7.1 TL01. |
| FreeBSD | x | x | - | |
| OpenBSD | x | x | - | |
| Solaris | x | x | - | |
| NetBSD | x | x | - | |
| HP-UX | x | x | - | |

Note:

Zabbix server/agent may work on other Unix-like operating systems.

Attention:

Zabbix disables core dumps if compiled with encryption and does not start if the system does not allow disabling of core dumps.

Required software

Zabbix is built around modern web servers, leading database engines, and PHP scripting language.

Third-party external surrounding software

If stated as mandatory, the required software/library is strictly necessary. Optional ones are needed for supporting some specific function.

| Software | Mandatory status | Supported versions | Comments |
|-----------------------------------|------------------|--------------------|--|
| <i>MySQL/Percona</i> | One of | 8.0.30-9.0.X | Required if MySQL (or Percona) is used as Zabbix backend database. InnoDB engine is required. |
| <i>MariaDB</i> | | 10.5.00-11.5.X | We recommend using the C API (libmysqlclient) library for building server/proxy. InnoDB engine is required. The recommended version is 11.4. We recommend using the MariaDB Connector/C library for building server/proxy. |
| <i>PostgreSQL</i> | | 13.0-17.X | See also: Possible deadlocks with MariaDB and Access to UI elements with MariaDB 10.5.1-10.5.9 . Required if PostgreSQL is used as Zabbix backend database. Depending on the installation size, it might be required to increase PostgreSQL <i>work_mem</i> configuration property (4MB being the default value), so that the amount of memory used by the database for particular operation is sufficient and query execution does not take too much time. |
| <i>TimescaleDB for PostgreSQL</i> | | 2.13.0-2.19.X | Required if TimescaleDB is used as a PostgreSQL database extension. Make sure to install TimescaleDB Community Edition, which supports compression. Note that PostgreSQL 15 is supported since TimescaleDB 2.10. You may also refer to Timescale documentation for details regarding PostgreSQL and TimescaleDB version compatibility. |
| <i>SQLite</i> | Optional | 3.3.5-3.34.X | Added support for TimescaleDB versions: - 2.18.X since Zabbix 7.2.4; - 2.19.X since Zabbix 7.2.7. SQLite is only supported with Zabbix proxies. Required if SQLite is used as Zabbix proxy database. |
| <i>smartmontools</i> | | 7.1 or later | Required for Zabbix agent 2. |
| <i>who</i> | | | Required for the user count plugin. |
| <i>dpkg</i> | | | Required for the system.sw.packages plugin. |
| <i>pkgtool</i> | | | Required for the system.sw.packages plugin. |
| <i>rpm</i> | | | Required for the system.sw.packages plugin. |
| <i>pacman</i> | | | Required for the system.sw.packages plugin. |
| <i>q applets</i> | | | qlist and qsize, as part of q applets , are required for the system.sw.packages plugin on Gentoo Linux. |

Note:

Although Zabbix can work with databases available in the operating systems, for the best experience, we recommend using databases installed from the official database developer repositories.

Frontend

The minimum supported screen width for Zabbix frontend is 1200px.

If stated as mandatory, the required software/library is strictly necessary. Optional ones are needed for supporting some specific function.

| Software | Mandatory status | Supported versions | Comments |
|-------------------------------|------------------|-------------------------------|--|
| <i>PHP</i> | Yes | 8.0.0 - 8.4.X | Added support for PHP versions: - 8.4.X since Zabbix 7.2.4. |
| <i>Apache</i> <i>Nginx</i> | One of | 2.4 or later 1.20 or later | |

| Software | Mandatory status | Supported versions | Comments |
|---|------------------|--------------------|--|
| MySQL PostgreSQL PHP extensions | One of | | |
| <i>mysqli</i> <i>pgsql</i> <i>bcmath</i> <i>mbstring</i> <i>sockets</i> <i>gd</i> | Yes | 2.0.28 or later | Required if MySQL is used as Zabbix backend database. Required if PostgreSQL is used as Zabbix backend database. php-bcmath (<i>--enable-bcmath</i>) php-mbstring (<i>--enable-mbstring</i>) php-net-socket (<i>--enable-sockets</i>); required for user script support. php-gd (if provided as a separate package by the distributor); PHP GD extension must support PNG images (<i>--with-png-dir</i>), JPEG images (<i>--with-jpeg-dir</i>), and FreeType 2 (<i>--with-freetype-dir</i>). Version 2.3.0 or later may be required to avoid possible text overlapping in graphs for some frontend languages. |
| <i>libxml</i> <i>xmlwriter</i> <i>xmlreader</i> <i>ctype</i> <i>session</i> <i>ldap</i> <i>openssl</i> <i>gettext</i> <i>curl</i> | No | 2.6.15 or later | php-xml (if provided as a separate package by the distributor) php-xmlwriter (if provided as a separate package by the distributor) php-xmlreader (if provided as a separate package by the distributor) php-ctype (<i>--enable-ctype</i>) php-session (if provided as a separate package by the distributor) php-ldap; required for LDAP authentication. php-openssl; required for SAML authentication. php-gettext (<i>--with-gettext</i>); required for translations. php-curl; required for the Duo Universal Prompt multi-factor authentication option. |

Third-party frontend libraries that are supplied with Zabbix:

| Library | Mandatory status | Minimum version | Comments |
|--|------------------|-----------------|--|
| jQuery JavaScript Library jQuery UI | Yes | 3.6.0 1.12.1 | JavaScript library that simplifies the process of cross-browser development. A set of user interface interactions, effects, widgets, and themes built on top of jQuery. |
| SAML PHP Toolkit | | 4.0.0 | A PHP toolkit that adds SAML 2.0 authentication support to be able to sign in to Zabbix. |
| Symfony Yaml Component | | 5.1.0 | Adds support to export and import Zabbix configuration elements in the YAML format. |

Note:

Zabbix may work on previous versions of Apache, MySQL, and PostgreSQL as well.

Attention:

For other fonts than the default DejaVu, PHP function [imagerotate](#) might be required. If it is missing, these fonts might be rendered incorrectly when a graph is displayed. This function is only available if PHP is compiled with bundled GD, which is not the case in Debian and other distributions.

Third-party libraries used for writing and debugging Zabbix frontend code:

| Library | Mandatory status | Minimum version | Description |
|--------------------------|------------------|-----------------|--|
| Composer | No | 2.4.1 | An application-level package manager for PHP that provides a standard format for managing dependencies of PHP software and required libraries. |
| PHPUnit | | 8.5.29 | A PHP unit testing framework for testing Zabbix frontend. |
| SASS | | 3.4.22 | A preprocessor scripting language that is interpreted and compiled into Cascading Style Sheets (CSS). |

Web browser on client side

Cookies and JavaScript must be enabled.

The latest stable versions of Google Chrome, Mozilla Firefox, Microsoft Edge, Apple Safari, and Opera are supported.

Warning:

The same-origin policy for IFrames is implemented, which means that Zabbix cannot be placed in frames on a different domain.

Still, pages placed into a Zabbix frame will have access to Zabbix frontend (through JavaScript) if the page that is placed in the frame and Zabbix frontend are on the same domain. A page like `http://secure-zabbix.com/cms/page.html`, if placed into dashboards on `http://secure-zabbix.com/zabbix/`, will have full JS access to Zabbix.

Server/proxy

If stated as mandatory, the required software/library is strictly necessary. Optional ones are needed for supporting some specific function.

| Requirement | Mandatory status | Description |
|---------------------------------------|------------------|---|
| <i>libpcre/libpcre2</i> | One of | PCRE/PCRE2 library is required for Perl Compatible Regular Expression (PCRE) support. The naming may differ depending on the GNU/Linux distribution, for example 'libpcre3' or 'libpcre1'. PCRE v8.x and PCRE2 v10.x are supported. |
| <i>libevent</i> | Yes | Required for inter-process communication. Version 2.0.10 or higher. |
| <i>libevent-pthreads</i> | | Required for inter-process communication. |
| <i>libpthread</i> | | Required for mutex and read-write lock support (could be part of libc). |
| <i>libresolv</i> | | Required for DNS resolution (could be part of libc). |
| <i>libiconv</i> | | Required for text encoding/format conversion (could be part of libc). Mandatory for Zabbix server on Linux. |
| <i>libz</i> | One of | Required for compression support. |
| <i>libm</i> | | Math library. Required by Zabbix server only. |
| <i>libmysqlclient</i> | | Required if MySQL is used. |
| <i>libmariadb</i> | | Required if MariaDB is used. |
| <i>libpq5</i> | | Required if PostgreSQL is used; <i>libpq5</i> version must match or be higher than the version of the PostgreSQL database used. |
| <i>libsqlite3</i> | No | Required if SQLite is used. Required for Zabbix proxy only. |
| <i>libOpenIPMI</i> | | Required for IPMI support. Required for Zabbix server only. |
| <i>libssh2</i> or <i>libssh</i> | | Required for SSH checks . Version 1.0 or higher (libssh2); 0.9.0 or higher (libssh). |
| <i>libcurl</i> | | Required for web monitoring, VMware monitoring, SMTP authentication, <code>web.page.*</code> Zabbix agent items , HTTP agent items and Elasticsearch (if used). Version 7.19.1 or higher is required (7.28.0 or higher is recommended). Libcurl version requirements: - SMTP authentication: version 7.20.0 or higher - Elasticsearch: version 7.28.0 or higher To make use of upgraded cURL features, restart Zabbix server/proxy and agent (for <code>web.page.*</code> items). |
| <i>libxml2</i> | | Required for VMware monitoring and XML XPath preprocessing. |
| <i>net-snmp</i> | | Required for SNMP support. Version 5.3.0 or higher. Support of strong encryption protocols (AES192/AES192C, AES256/AES256C) is available starting with net-snmp library 5.8; on RHEL 8+ based systems it is recommended to use net-snmp 5.8.15 or later. |
| <i>libunixodbc</i> | | Required for database monitoring. |
| <i>libgnutls</i> or <i>libopenssl</i> | | Required when using encryption . Minimum versions: <i>libgnutls</i> - 3.1.18, <i>libopenssl</i> - 1.0.1 |
| <i>libldap</i> | | Required for LDAP support. |
| <i>fping</i> | | Required for ICMP ping items . |
| <i>c-ares</i> | | Required for asynchronous DNS resolution if Zabbix is configured with <code>--with-ares</code> option. Otherwise, <i>libevent</i> will be used. Supported since Zabbix 7.2.5; minimum version: 1.16.0 |

Agent

| Requirement | Mandatory status | Description |
|---------------------------------------|------------------|--|
| <i>libpcre/libpcre2</i> | One of | PCRE/PCRE2 library is required for Perl Compatible Regular Expression (PCRE) support. The naming may differ depending on the GNU/Linux distribution, for example 'libpcre3' or 'libpcre1'. PCRE v8.x and PCRE2 v10.x are supported. Required for log monitoring. Also required on Windows. |
| <i>libpthread</i> | Yes | Required for mutex and read-write lock support (could be part of libc). Not required on Windows. |
| <i>libresolv</i> | | Required for DNS resolution (could be part of libc). Not required on Windows. |
| <i>libiconv</i> | | Required for text encoding/format conversion to UTF-8 in log items, file content, file regex and regmatch items (could be part of libc). Not required on Windows. |
| <i>libgnutls</i> or <i>libopenssl</i> | No | Required if using encryption . Minimum versions: <i>libgnutls</i> - 3.1.18, <i>libopenssl</i> - 1.0.1 On Microsoft Windows OpenSSL 1.1.1 or later is required. |
| <i>libldap</i> | | Required if LDAP is used. Not supported on Windows. |
| <i>libcurl</i> | | Required for <code>web.page.*</code> Zabbix agent items . Not supported on Windows. Version 7.19.1 or higher is required (7.28.0 or higher is recommended). To make use of upgraded cURL features, restart Zabbix agent. |
| <i>libmodbus</i> | | Only required if Modbus monitoring is used. Version 3.0 or higher. |

Agent 2

| Requirement | Mandatory status | Description |
|-------------------------|------------------|---|
| <i>Go</i> | Yes | Required to build Zabbix agent 2 and its plugins from source. Go 1.23 or later is supported. See go.dev for installation instructions. Go libraries used by Zabbix agent 2 and its plugins are listed in the Zabbix Git repository (libraries marked as <code>indirect</code> in the repository are dependencies of other required libraries): - Zabbix agent 2 - Plugin support - PostgreSQL - MongoDB - MSSQL - Ember+ - NVIDIA GPU - Example plugin |
| <i>libpcre/libpcre2</i> | One of | PCRE/PCRE2 library is required for Perl Compatible Regular Expression (PCRE) support. The naming may differ depending on the GNU/Linux distribution, for example 'libpcre3' or 'libpcre1'. PCRE v8.x and PCRE2 v10.x are supported. Required for log monitoring. Also required on Windows. |
| <i>libopenssl</i> | No | Required when using encryption. OpenSSL 1.0.1 or later is required on UNIX platforms. The OpenSSL library must have PSK support enabled. LibreSSL is not supported. On Microsoft Windows systems OpenSSL 1.1.1 or later is required. |

Web service

The latest stable version of Google Chrome is supported for generating scheduled reports using the Zabbix web service.

The required Go version for building the web service matches the one used for **Zabbix agent 2**.

Java gateway

If you obtained Zabbix from the source repository or an archive, then the necessary dependencies are already included in the source tree.

If you obtained Zabbix from your distribution's package, then the necessary dependencies are already provided by the packaging system.

In both cases above, the software is ready to be used and no additional downloads are necessary.

If, however, you wish to provide your versions of these dependencies (for instance, if you are preparing a package for some Linux distribution), below is the list of library versions that Java gateway is known to work with. Zabbix may work with other versions of these libraries, too.

The following table lists JAR files that are currently bundled with Java gateway in the original code:

| Library | Mandatory status | Minimum version | Comments |
|---------------------------------|------------------|-----------------|--|
| android-json | Yes | 4.3r1 | JSON (JavaScript Object Notation) is a lightweight data-interchange format. This is the org.json compatible Android implementation extracted from the Android SDK. |
| logback-classic | | 1.5.16 | |
| logback-core | | 1.5.16 | |
| slf4j-api | | 2.0.16 | |

Java gateway can be built using either Oracle Java or open source OpenJDK (version 1.6 or newer). Packages provided by Zabbix are compiled using OpenJDK. The following table lists OpenJDK packages used for building Zabbix packages by distribution:

| Distribution | OpenJDK package |
|--------------------|--|
| AlmaLinux 9 | java-11-openjdk-devel (amd64: 11.0.19.0.7-4; arm64: 11.0.20.0.8-3) |
| AlmaLinux 8 | java-1.8.0-openjdk-devel (amd64: 1.8.0.332.b09-2; arm64: 1.8.0.382.b05-2) |
| Amazon Linux 2023 | java-22-amazon-corretto-devel (amd64, arm64: 22.0.2+9-1) |
| CentOS Stream 9 | java-11-openjdk-devel (amd64, arm64: 11.0.18.0.10-3) |
| CentOS Stream 8 | java-1.8.0-openjdk-devel (amd64, arm64: 1.8.0.362.b08-3) |
| CentOS 7 | java-1.8.0-openjdk-devel (amd64: 1.8.0.282.b08-1) |
| Debian 12 | default-jdk-headless (amd64, arm64: 2:1.17-74) |
| Debian 11 | default-jdk-headless (amd64: 2:1.11-72) |
| OpenSUSE Leap 15 | java-17-openjdk-devel (amd64: 17.0.5.0-150400.3.9.3; arm64: 17.0.8.0-150400.3.27.1) |
| Oracle Linux 9 | java-11-openjdk-devel (amd64: 11.0.19.0.7-4.0.1; arm64: 11.0.20.0.8-2.0.1) |
| Oracle Linux 8 | java-1.8.0-openjdk-devel (amd64: 1.8.0.372.b07-4.0.1); java-11-openjdk-devel (arm64: 11.0.20.0.8-3.0.1) |
| Oracle Linux 7 | java-1.8.0-openjdk-devel (amd64: 1.8.0.282.b08-1) |
| Raspberry Pi OS 12 | default-jdk-headless (arm64, armhf: 2:1.17-74) |
| Raspberry Pi OS 11 | default-jdk-headless (arm64: 2:1.11-72; armhf: 2:1.11-72+b4) |
| RHEL 9 | java-11-openjdk-devel (amd64: 11.0.19.0.7-4; arm64: 11.0.20.0.8-3) |
| RHEL 8 | java-1.8.0-openjdk-devel (amd64: 1.8.0.372.b07-4; arm64: 1.8.0.382.b05-2) |
| RHEL 7 | java-1.8.0-openjdk-devel (amd64: 1.8.0.282.b08-1) |
| Rocky Linux 9 | java-11-openjdk-devel (amd64: 11.0.19.0.7-4; arm64: 11.0.20.0.8-3) |
| Rocky Linux 8 | java-1.8.0-openjdk-devel (amd64: 1.8.0.372.b07-4; arm64: 1.8.0.382.b05-2) |
| SLES 15 | java-17-openjdk-devel (amd64: 17.0.5.0-150400.3.9.3; arm64: 17.0.8.0-150400.3.27.1) |
| Ubuntu 24.04 | default-jdk-headless (amd64, arm64: 2:1.21-75+exp1) |
| Ubuntu 22.04 | default-jdk-headless (amd64, arm64: 2:1.11-72build2) |
| Ubuntu 20.04 | default-jdk-headless (amd64, arm64: 2:1.11-72) |

Default port numbers

The following list of open ports per component is applicable for default configuration:

| Zabbix component | Port number | Protocol | Type of connection |
|---------------------|-------------|----------|--------------------|
| Zabbix agent | 10050 | TCP | on demand |
| Zabbix agent 2 | 10050 | TCP | on demand |
| Zabbix server | 10051 | TCP | on demand |
| Zabbix proxy | 10051 | TCP | on demand |
| Zabbix Java gateway | 10052 | TCP | on demand |
| Zabbix web service | 10053 | TCP | on demand |
| Zabbix frontend | 80 | HTTP | on demand |
| | 443 | HTTPS | on demand |
| Zabbix trapper | 10051 | TCP | on demand |

Note:

The port numbers should be open in firewall to enable Zabbix communications. Outgoing TCP connections usually do not require explicit firewall settings.

Database size

Zabbix configuration data require a fixed amount of disk space and do not grow much.

Zabbix database size mainly depends on these variables, which define the amount of stored historical data:

- Number of processed values per second

This is the average number of new values Zabbix server receives every second. For example, if we have 3000 items for monitoring with a refresh rate of 60 seconds, the number of values per second is calculated as $3000/60 = 50$.

It means that 50 new values are added to Zabbix database every second.

- Housekeeper settings for history

Zabbix keeps values for a fixed period of time, normally several weeks or months. Each new value requires a certain amount of disk space for data and index.

So, if we would like to keep 30 days of history and we receive 50 values per second, the total number of values will be around $(30*24*3600)*50 = 129.600.000$, or about 130M of values.

Depending on the database engine used, type of received values (floats, integers, strings, log files, etc), the disk space for keeping a single value may vary from 40 bytes to hundreds of bytes. Normally it is around 90 bytes per value for numeric items². In our case, it means that 130M of values will require $130M * 90 \text{ bytes} = 10.9GB$ of disk space.

Note:

The size of text/log item values is impossible to predict exactly, but you may expect around 500 bytes per value.

- Housekeeper setting for trends

Zabbix keeps a 1-hour max/min/avg/count set of values for each item in the table **trends**. The data is used for trending and long period graphs. The one hour period can not be customized.

Zabbix database, depending on the database type, requires about 90 bytes per each total. Suppose we would like to keep trend data for 5 years. Values for 3000 items will require $3000*24*365*90 = 2.2GB$ per year, or **11GB** for 5 years.

- Housekeeper settings for events

Each Zabbix event requires approximately 250 bytes of disk space¹. It is hard to estimate the number of events generated by Zabbix daily. In the worst-case scenario, we may assume that Zabbix generates one event per second.

For each recovered event, an event_recovery record is created. Normally most of the events will be recovered so we can assume one event_recovery record per event. That means additional 80 bytes per event.

Optionally events can have tags, each tag record requiring approximately 100 bytes of disk space¹. The number of tags per event (#tags) depends on configuration. So each will need an additional #tags * 100 bytes of disk space.

It means that if we want to keep 3 years of events, this would require $3*365*24*3600*(250+80+\#tags*100) = \sim 30GB + \#tags*100B$ disk space².

Note:

¹ More when having non-ASCII event names, tags and values.

² The size approximations are based on MySQL and might be different for other databases.

The table contains formulas that can be used to calculate the disk space required for Zabbix system:

| Parameter | Formula for required disk space (in bytes) |
|-----------------------------|---|
| <i>Zabbix configuration</i> | Fixed size. Normally 10MB or less. |
| <i>History</i> | $\text{days} * (\text{items} / \text{refresh rate}) * 24 * 3600 * \text{bytes}$ items : number of items days : number of days to keep history refresh rate : average refresh rate of items bytes : number of bytes required to keep single value, depends on database engine, normally ~90 bytes. |

| Parameter | Formula for required disk space (in bytes) |
|---------------|--|
| <i>Trends</i> | $\text{days} * (\text{items} / 3600) * 24 * 3600 * \text{bytes}$ items : number of items days : number of days to keep history bytes : number of bytes required to keep single trend, depends on the database engine, normally ~90 bytes. |
| <i>Events</i> | $\text{days} * \text{events} * 24 * 3600 * \text{bytes}$ events : number of event per second. One (1) event per second in worst-case scenario. days : number of days to keep history bytes : number of bytes required to keep single trend, depends on the database engine, normally ~330 + average number of tags per event * 100 bytes. |

So, the total required disk space can be calculated as:

Configuration + History + Trends + Events

The disk space will NOT be used immediately after Zabbix installation. Database size will grow then it will stop growing at some point, which depends on housekeeper settings.

Time synchronization

It is very important to have precise system time on the server with Zabbix running. [ntpd](#) is the most popular daemon that synchronizes the host's time with the time of other machines. It's strongly recommended to maintain synchronized system time on all systems Zabbix components are running on.

Network requirements

A following list of open ports per component is applicable for default configuration.

| Port | Components |
|---------------|--|
| Frontend | http on 80, https on 443 |
| Server | 10051 (for use with active proxy/agents) |
| Active Proxy | 10051 |
| Passive Proxy | 10051 |
| Agent2 | 10050 |
| Trapper | |
| JavaGateway | 10052 |
| WebService | 10053 |

Note:

The port numbers should be opened in the firewall to enable external communications with Zabbix. Outgoing TCP connections usually do not require explicit firewall settings.

3 Installation from sources

You can get the very latest version of Zabbix by compiling it from the sources.

A step-by-step tutorial for installing Zabbix from the sources is provided [here](#).

1 Installing Zabbix daemons

1 Download the source archive

Go to the [Zabbix download page](#) and download the source archive. Once downloaded, extract the sources, by running:

```
tar -zxvf zabbix-7.2.0.tar.gz
```

Note:

Enter the correct Zabbix version in the command. It must match the name of the downloaded archive.

2 Create user account

All Zabbix daemon processes run under unprivileged system users. If a Zabbix daemon is started from an unprivileged user account, it will continue running as that user.

In the default configuration, if a daemon is started as root, it will switch to the zabbix user account, which must be present. To create a zabbix system user and group, run the commands listed below.

RedHat-based system:

```
groupadd --system zabbix
useradd --system -g zabbix -d /usr/lib/zabbix -s /sbin/nologin -c "Zabbix Monitoring System" zabbix
```

Debian-based system:

```
addgroup --system --quiet zabbix
adduser --quiet --system --disabled-login --ingroup zabbix --home /var/lib/zabbix --no-create-home zabbix
```

There is no need to create a separate user account for Zabbix frontend.

Security recommendation

If the Zabbix **server** and **agent** run on the same machine, it is recommended to run them under **separate user accounts**. Running both as the same user allows the agent to access the server's configuration file, which could expose sensitive information—such as the database password—to any Admin-level user in Zabbix.

Attention:

Running Zabbix as root, bin, or any other account with special rights is a security risk.

Home directory (optional)

Zabbix processes do not require a home directory, so creating one is generally not recommended. However, if you need functionality that requires a home directory (for example, storing MySQL credentials in \$HOME/.my.cnf), you can create it using the commands listed below.

On RedHat-based systems, run:

```
mkdir -m u=rwx,g=rwx,o=-p /usr/lib/zabbix
chown zabbix:zabbix /usr/lib/zabbix
```

On Debian-based systems, run:

```
mkdir -m u=rwx,g=rwx,o=-p /var/lib/zabbix
chown zabbix:zabbix /var/lib/zabbix
```

3 Create Zabbix database

For Zabbix **server** and **proxy** daemons, as well as Zabbix frontend, a database is required. It is not needed to run Zabbix **agent**.

SQL **scripts are provided** for creating database schema and inserting the dataset. Zabbix proxy database needs only the schema while Zabbix server database requires also the dataset on top of the schema.

Having created a Zabbix database, proceed to the following steps of compiling Zabbix.

4 Configure the sources

C99 with GNU extensions is required for building Zabbix server, Zabbix proxy or Zabbix agent. This version can be explicitly specified by setting CFLAGS="-std=gnu99":

```
export CFLAGS="-std=gnu99"
```

Note:

If installing from [Zabbix Git repository](#), it is required to run first:

```
./bootstrap.sh
```

When configuring the sources for a Zabbix server or proxy, you must specify the database type to be used. Only one database type can be compiled with a server or proxy process at a time.

To see all of the supported configuration options, inside the extracted Zabbix source directory run:

```
./configure --help
```

To configure the sources for a Zabbix server and agent, you may run something like:

```
./configure --enable-server --enable-agent --with-mysql --enable-ipv6 --with-net-snmp --with-libcurl --with-
```

To configure the sources for a Zabbix server (with PostgreSQL etc.), you may run:

```
./configure --enable-server --with-postgresql --with-net-snmp
```

To configure the sources for a Zabbix proxy (with SQLite etc.), you may run:

```
./configure --prefix=/usr --enable-proxy --with-net-snmp --with-sqlite3 --with-ssh2
```

To configure the sources for a Zabbix agent, you may run:

```
./configure --enable-agent
```

or, for Zabbix agent 2:

```
./configure --enable-agent2
```

Note:

A configured Go environment with a **supported Go version** is required for building Zabbix agent 2.

Notes on compilation options:

- Command-line utilities `zabbix_get` and `zabbix_sender` are compiled if `--enable-agent` option is used.
- `--with-libcurl` and `--with-libxml2` configuration options are required for virtual machine monitoring; `--with-libcurl` is also required for SMTP authentication and `web.page.*` Zabbix agent **items**. Note that cURL 7.20.0 or higher is **required** with the `--with-libcurl` configuration option.
- Zabbix always compiles with the PCRE library; installing it is not optional. `--with-libpcre=[DIR]` only allows pointing to a specific base install directory, instead of searching through a number of common places for the libpcre files.
- You may use the `--enable-static` flag to statically link libraries. If you plan to distribute compiled binaries among different servers, you must use this flag to make these binaries work without required libraries. Note that `--enable-static` does not work in **Solaris**.
- Using `--enable-static` option is not recommended when building server. In order to build the server statically, you must have a static version of every external library needed. There is no strict check for that in configure script.
- Add optional path to the MySQL configuration file `--with-mysql=``<path_to_the_file>/mysql_config` to select the desired MySQL client library when there is a need to use one that is not located in the default location. It is useful when there are several versions of MySQL installed or MariaDB installed alongside MySQL on the same system.

Attention:

If `./configure` fails due to missing libraries or some other circumstance, please see the `config.log` file for more details on the error. For example, if `libssl` is missing, the immediate error message may be misleading:

```
checking for main in -lmysqlclient... no
configure: error: Not found mysqlclient library
While config.log has a more detailed description:
/usr/bin/ld: cannot find -lssl
/usr/bin/ld: cannot find -lcrypto
```

See also:

- **Compiling Zabbix with encryption support** for encryption support
- **Known issues** with compiling Zabbix agent on HP-UX

5 Make and install everything

Note:

If installing from **Zabbix Git repository**, it is required to run first:

```
$ make dbschema
```

`make install`

This step should be run as a user with sufficient permissions (commonly 'root', or by using `sudo`).

Running `make install` will by default install the daemon binaries (`zabbix_server`, `zabbix_agentd`, `zabbix_proxy`) in `/usr/local/sbin` and the client binaries (`zabbix_get`, `zabbix_sender`) in `/usr/local/bin`.

Note:

To specify a different location than `/usr/local`, use a `--prefix` key in the previous step of configuring sources, for example `--prefix=/home/zabbix`. In this case daemon binaries will be installed under `<prefix>/sbin`, while utilities under `<prefix>/bin`. Man pages will be installed under `<prefix>/share`.

6 Review and edit configuration files

- edit the Zabbix agent configuration file **/usr/local/etc/zabbix_agentd.conf**

You need to configure this file for every host with zabbix_agentd installed.

You must specify the Zabbix server **IP address** in the file. Connections from other hosts will be denied.

- edit the Zabbix server configuration file **/usr/local/etc/zabbix_server.conf**

You must specify the database name, user and password (if using any).

The rest of the parameters will suit you with their defaults if you have a small installation (up to ten monitored hosts). You should change the default parameters if you want to maximize the performance of Zabbix server (or proxy) though.

- if you have installed a Zabbix proxy, edit the proxy configuration file **/usr/local/etc/zabbix_proxy.conf**

You must specify the server IP address and proxy hostname (must be known to the server), as well as the database name, user and password (if using any).

Note:

With SQLite the full path to database file must be specified; DB user and password are not required.

7 Start up the daemons

Run zabbix_server on the server side.

zabbix_server

Note:

Make sure that your system allows allocation of 36MB (or a bit more) of shared memory, otherwise the server may not start and you will see "Cannot allocate shared memory for <type of cache>." in the server log file. This may happen on FreeBSD, Solaris 8.

Run zabbix_agentd on all the monitored machines.

zabbix_agentd

Note:

Make sure that your system allows allocation of 2MB of shared memory, otherwise the agent may not start and you will see "Cannot allocate shared memory for collector." in the agent log file. This may happen on Solaris 8.

If you have installed Zabbix proxy, run zabbix_proxy.

zabbix_proxy

2 Installing Zabbix web interface

Copying PHP files

Zabbix frontend is written in PHP, so to run it a PHP supported webserver is needed. Installation is done by simply copying the PHP files from the ui directory to the webserver HTML documents directory.

Common locations of HTML documents directories for Apache web servers include:

- /usr/local/apache2/htdocs (default directory when installing Apache from source)
- /srv/www/htdocs (OpenSUSE, SLES)
- /var/www/html (Debian, Ubuntu, Fedora, RHEL)

It is suggested to use a subdirectory instead of the HTML root. To create a subdirectory and copy Zabbix frontend files into it, execute the following commands, replacing the <htdocs> with actual directory:

```
mkdir <htdocs>/zabbix
cd ui
cp -a . <htdocs>/zabbix
```

If planning to use any other language than English, see [Installation of additional frontend languages](#) for instructions.

Installing frontend

Please see [Web interface installation](#) page for information about Zabbix frontend installation wizard.

3 Installing Java gateway

It is required to install Java gateway only if you want to monitor JMX applications. Java gateway is lightweight and does not require a database.

To install from sources, first **download** and extract the source archive.

To compile Java gateway, run the `./configure` script with `--enable-java` option. It is advisable that you specify the `--prefix` option to request installation path other than the default `/usr/local`, because installing Java gateway will create a whole directory tree, not just a single executable.

```
./configure --enable-java --prefix=$PREFIX
```

To compile and package Java gateway into a JAR file, run `make`. Note that for this step you will need `javac` and `jar` executables in your path.

```
make
```

Now you have a `zabbix-java-gateway-$VERSION.jar` file in `src/zabbix_java/bin`. If you are comfortable with running Java gateway from `src/zabbix_java` in the distribution directory, then you can proceed to instructions for configuring and running **Java gateway**. Otherwise, make sure you have enough privileges and run `make install`.

```
make install
```

Proceed to **setup** for more details on configuring and running Java gateway.

4 Installing Zabbix web service

Installing Zabbix web service is only required if you want to use **scheduled reports**.

To install from sources, first **download** and extract the source archive.

To compile Zabbix web service, run the `./configure` script with `--enable-webservice` option.

Note:

A configured Go environment with a **supported Go version** is required for building Zabbix web service.

Run `zabbix_web_service` on the machine, where the web service is installed:

```
zabbix_web_service
```

Proceed to **setup** for more details on configuring Scheduled reports generation.

1 Building Zabbix agent on Windows

Overview

This section demonstrates how to build Zabbix Windows agent binaries from sources with or without TLS.

Compiling OpenSSL

The following steps will help you compile OpenSSL from sources on MS Windows 10 (64-bit).

1. Before proceeding, check that the Windows machine has:
 - C compiler (e.g. VS 2017 RC);
 - NASM (<https://www.nasm.us/>);
 - Perl (e.g. Strawberry Perl from <http://strawberryperl.com/>);
 - Perl module `Text::Template` (`cpan Text::Template`).
2. Get OpenSSL sources from <https://www.openssl.org/>. This example uses OpenSSL 1.1.1.
3. Unpack OpenSSL sources, for example, into `E:\openssl-1.1.1`.
4. Open a command-line window, such as the x64 Native Tools Command Prompt for VS 2017 RC.
5. Go to the OpenSSL source directory (in this tutorial `E:\openssl-1.1.1`) and verify that NASM can be found:

```
e:\openssl-1.1.1> nasm --version
NASM version 2.13.01 compiled on May  1 2017
```

6. Configure OpenSSL, for example:

```
e:\openssl-1.1.1> perl E:\openssl-1.1.1\Configure VC-WIN64A no-shared no-capieng no-srp no-gost no-dgram n
```

Attention:

Make sure to revoke write access from non-administrator users to the OpenSSL install directory (C:\OpenSSL-Win64-111-static). Otherwise, Zabbix agent will load SSL settings from a path that can be modified by unprivileged users, resulting in a potential security vulnerability.

- Note the option 'no-shared': if 'no-shared' is used then the OpenSSL static libraries libcrypto.lib and libssl.lib will be 'self-sufficient' and resulting Zabbix binaries will include OpenSSL in themselves, no need for external OpenSSL DLLs. Advantage: Zabbix binaries can be copied to other Windows machines without OpenSSL libraries. Disadvantage: when a new OpenSSL bugfix version is released, Zabbix agent needs to be recompiled and reinstalled.
- If 'no-shared' is not used, then the static libraries libcrypto.lib and libssl.lib will be using OpenSSL DLLs at runtime. Advantage: when a new OpenSSL bugfix version is released, probably you can upgrade only OpenSSL DLLs, without recompiling Zabbix agent. Disadvantage: copying Zabbix agent to another machine requires copying OpenSSL DLLs too.

7. Compile OpenSSL, run tests, install:

```
e:\openssl-1.1.1> nmake
e:\openssl-1.1.1> nmake test
```

```
...
```

All tests successful.

Files=152, Tests=1152, 501 wallclock secs (0.67 usr + 0.61 sys = 1.28 CPU)

Result: PASS

```
e:\openssl-1.1.1> nmake install_sw
```

install_sw installs only software components (i.e. libraries, header files, but no documentation). To install everything, use `nmake install`.

Compiling PCRE

1. Download the PCRE or PCRE2 library (<https://pcre.org/>).
2. Extract to directory `E:\pcre2-10.39`.
3. Install CMake from <https://cmake.org/download/>, during install select: and ensure that `cmake\bin` is on your path (tested version 3.9.4).
4. Create a new, empty build directory, preferably a subdirectory of the source dir. For example, `E:\pcre2-10.39\build`.
5. Open a command-line window e.g. the x64 Native Tools Command Prompt for VS 2017 and from that shell environment run `cmake-gui`. Do not try to start Cmake from the Windows Start menu, as this can lead to errors.
6. Enter `E:\pcre2-10.39` and `E:\pcre2-10.39\build` for the source and build directories, respectively.
7. Click the "Configure" button.
8. When specifying the generator for this project select "NMake Makefiles".
9. Create a new, empty install directory. For example, `E:\pcre2-10.39-install`.
10. The GUI will then list several configuration options. Make sure the following options are selected:

- **PCRE_SUPPORT_UNICODE_PROPERTIES** ON
- **PCRE_SUPPORT_UTF** ON
- **CMAKE_INSTALL_PREFIX** `E:\pcre2-10.39-install`

11. Click "Configure" again. The adjacent "Generate" button should now be active.
12. Click "Generate".
13. If any errors occur, it is recommended to delete the CMake cache before attempting to repeat the CMake build process. In the CMake GUI, the cache can be deleted by selecting "File > Delete Cache".
14. The build directory should now contain a usable build system - *Makefile*.
15. Open a command-line window such as the x64 Native Tools Command Prompt for VS 2017 and navigate to the *Makefile* mentioned above.
16. Run NMake command:

```
E:\pcre2-10.39\build> nmake install
```

Compiling Zabbix

The following steps will help you to compile Zabbix from sources on MS Windows 10 (64-bit). When compiling Zabbix with/without TLS support the only significant difference is in step 4.

1. On a Linux machine check out the source from git:

```
git clone https://git.zabbix.com/scm/zbx/zabbix.git
cd zabbix
./bootstrap.sh
./configure --enable-agent --enable-ipv6 --prefix=`pwd`
make dbschema
make dist
```

2. Copy and unpack the archive, e.g. zabbix-7.0.0.tar.gz, on a Windows machine.
3. Let's assume that sources are in E:\zabbix-7.0.0. Open a command-line window, such as the x64 Native Tools Command Prompt for VS 2017 RC. Go to:

```
E:\zabbix-7.0.0\build\win32\project
```

1. On a Linux machine check out the source from git:

```
$ git clone https://git.zabbix.com/scm/zbx/zabbix.git
$ cd zabbix
$ ./bootstrap.sh
$ ./configure --enable-agent --enable-ipv6 --prefix=`pwd`
$ make dbschema
$ make dist
```

2. Copy and unpack the archive, e.g. zabbix-7.2.0.tar.gz, on a Windows machine.
3. Let's assume that sources are in e:\zabbix-7.2.0. Open a command-line window e.g. the x64 Native Tools Command Prompt for VS 2017 RC. Go to: E:\zabbix-7.2.0\build\win32\project.
4. Compile zabbix_get, zabbix_sender and zabbix_agent.
 - without TLS:

```
E:\zabbix-7.2.0\build\win32\project> nmake /K PCRE2INCDIR=E:\pcre2-10.39-install\include PCRE2LIB=E:\pcre2-10.39-install\lib
```
 - with TLS:

```
E:\zabbix-7.2.0\build\win32\project> nmake /K -f Makefile_get TLS=openssl TLSINCDIR=C:\OpenSSL-Win64\include
E:\zabbix-7.2.0\build\win32\project> nmake /K -f Makefile_sender TLS=openssl TLSINCDIR="C:\OpenSSL-Win64\include"
E:\zabbix-7.2.0\build\win32\project> nmake /K -f Makefile_agent TLS=openssl TLSINCDIR=C:\OpenSSL-Win64\include
```
5. New binaries are located in E:\zabbix-7.2.0\bin\win64. Since OpenSSL was compiled with 'no-shared' option, Zabbix binaries contain OpenSSL within themselves and can be copied to other machines that do not have OpenSSL.

Compiling Zabbix with LibreSSL

The process is similar to compiling with OpenSSL, but you need to make small changes in files located in the build\win32\project directory:

- In Makefile_tls: delete /DHAVE_OPENSSL_WITH_PSK

To do so, find:

```
CFLAGS = $(CFLAGS) /DHAVE_OPENSSL /DHAVE_OPENSSL_WITH_PSK
```

and replace it with

```
CFLAGS = $(CFLAGS) /DHAVE_OPENSSL
```

- In Makefile_common.inc: add /NODEFAULTLIB:LIBCMT

To do so, find:

```
/MANIFESTUAC:"level='asInvoker' uiAccess='false'" /DYNAMICBASE:NO /PDB:${TARGETDIR}\$(TARGETNAME).pdb
```

and replace it with

```
/MANIFESTUAC:"level='asInvoker' uiAccess='false'" /DYNAMICBASE:NO /PDB:${TARGETDIR}\$(TARGETNAME).pdb /NODEFAULTLIB:LIBCMT
```

2 Building Zabbix agent 2 on Windows

Overview

This section demonstrates how to build Zabbix agent 2 (Windows) from sources.

Installing MinGW Compiler

1. Download MinGW-w64 with SJLJ (set jump/long jump) Exception Handling and Windows threads (for example x86_64-8.1.0-release-win32-sjlj-rt_v6-rev0.7z)

2. Extract and move to `c:\mingw`
3. Setup environmental variable

```
@echo off
set PATH=%PATH%;c:\mingw\bin
cmd
```

When compiling use Windows prompt instead of MSYS terminal provided by MinGW

Compiling PCRE development libraries

The following instructions will compile and install 64-bit PCRE libraries in `c:\dev\pcre` and 32-bit libraries in `c:\dev\pcre32`:

1. Download the PCRE or PCRE2 library (<https://pcre.org/>) and extract
2. Open `cmd` and navigate to the extracted sources

Build 64bit PCRE

1. Delete old configuration/cache if exists:

```
del CMakeCache.txt
rmdir /q /s CMakeFiles
```

2. Run `cmake` (CMake can be installed from <https://cmake.org/download/>):

```
cmake -G "MinGW Makefiles" -DCMAKE_C_COMPILER=gcc -DCMAKE_C_FLAGS="-O2 -g" -DCMAKE_CXX_FLAGS="-O2 -g" -DCM
```

3. Next, run:

```
mingw32-make clean
mingw32-make install
```

Build 32bit PCRE

1. Run:

```
mingw32-make clean
```

2. Delete `CMakeCache.txt`:

```
del CMakeCache.txt
rmdir /q /s CMakeFiles
```

3. Run `cmake`:

```
cmake -G "MinGW Makefiles" -DCMAKE_C_COMPILER=gcc -DCMAKE_C_FLAGS="-m32 -O2 -g" -DCMAKE_CXX_FLAGS="-m32 -C
```

4. Next, run:

```
mingw32-make install
```

Installing OpenSSL development libraries

1. Download 32 and 64 bit builds from <https://curl.se/windows/>
2. Extract files into `c:\dev\openssl\32` and `c:\dev\openssl` directories accordingly.
3. After that remove extracted `*.dll.a` (dll call wrapper libraries) as MinGW prioritizes them before static libraries.

Attention:

Make sure to revoke write access from non-administrator users to the OpenSSL install directory (`C:\dev\openssl132` or `C:\dev\openssl1`). Otherwise, Zabbix agent 2 will load SSL settings from a path that can be modified by unprivileged users, resulting in a potential security vulnerability.

Compiling Zabbix agent 2

32 bit

Open MinGW environment (Windows command prompt) and navigate to `build/mingw` directory in the Zabbix source tree.

Run:

```
mingw32-make clean
mingw32-make ARCH=x86 PCRE=c:\dev\pcre32 OPENSSL=c:\dev\openssl132
```

64 bit

Open MinGW environment (Windows command prompt) and navigate to `build/mingw` directory in the Zabbix source tree.

Run:

```
mingw32-make clean
mingw32-make PCRE=c:\dev\pcre OPENSSL=c:\dev\openssl
```

Note:

Both 32- and 64- bit versions can be built on a 64-bit platform, but only a 32-bit version can be built on a 32-bit platform. When working on the 32-bit platform, follow the same steps as for 64-bit version on 64-bit platform.

3 Building Zabbix agent on macOS

Overview

This section demonstrates how to build Zabbix macOS agent binaries from sources with or without TLS.

Prerequisites

You will need command line developer tools (Xcode is not required), Automake, pkg-config and PCRE (v8.x) or PCRE2 (v10.x). If you want to build agent binaries with TLS, you will also need OpenSSL or GnuTLS.

To install Automake and pkg-config, you will need a Homebrew package manager from <https://brew.sh/>. To install it, open terminal and run the following command:

```
/usr/bin/ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install)"
```

Then install Automake and pkg-config:

```
brew install automake
brew install pkg-config
```

Preparing PCRE, OpenSSL and GnuTLS libraries depends on the way how they are going to be linked to the agent.

If you intend to run agent binaries on a macOS machine that already has these libraries, you can use precompiled libraries that are provided by Homebrew. These are typically macOS machines that use Homebrew for building Zabbix agent binaries or for other purposes.

If agent binaries will be used on macOS machines that don't have the shared version of libraries, you should compile static libraries from sources and link Zabbix agent with them.

Building agent binaries with shared libraries

Install PCRE2 (replace *pcre2* with *pcre* in the commands below, if needed):

```
brew install pcre2
```

When building with TLS, install OpenSSL and/or GnuTLS:

```
brew install openssl
brew install gnutls
```

Download Zabbix source:

```
git clone https://git.zabbix.com/scm/zbx/zabbix.git
```

Build agent without TLS:

```
cd zabbix
./bootstrap.sh
./configure --sysconfdir=/usr/local/etc/zabbix --enable-agent --enable-ipv6
make
make install
```

Build agent with OpenSSL:

```
cd zabbix
./bootstrap.sh
./configure --sysconfdir=/usr/local/etc/zabbix --enable-agent --enable-ipv6 --with-openssl=/usr/local/opt/openssl
make
make install
```

Build agent with GnuTLS:

```
cd zabbix-source/
./bootstrap.sh
./configure --sysconfdir=/usr/local/etc/zabbix --enable-agent --enable-ipv6 --with-gnutls=/usr/local/opt/gnutls
make
make install
```

```
make
make install
```

Building agent binaries with static libraries without TLS

Let's assume that PCRE static libraries will be installed in \$HOME/static-libs. We will use PCRE2 10.39.

```
PCRE_PREFIX="$HOME/static-libs/pcre2-10.39"
```

Download and build PCRE with Unicode properties support:

```
mkdir static-libs-source
cd static-libs-source
curl --remote-name https://github.com/PhilipHazel/pcre2/releases/download/pcre2-10.39/pcre2-10.39.tar.gz
tar xf pcre2-10.39.tar.gz
cd pcre2-10.39
./configure --prefix="$PCRE_PREFIX" --disable-shared --enable-static --enable-unicode-properties
make
make check
make install
```

Download Zabbix source and build agent:

```
git clone https://git.zabbix.com/scm/zbx/zabbix.git
cd zabbix
./bootstrap.sh
./configure --sysconfdir=/usr/local/etc/zabbix --enable-agent --enable-ipv6 --with-libpcre2="$PCRE_PREFIX"
make
make install
```

Building agent binaries with static libraries with OpenSSL

When building OpenSSL, it's recommended to run `make test` after successful building. Even if building was successful, tests sometimes fail. If this is the case, problems should be researched and resolved before continuing.

Let's assume that PCRE and OpenSSL static libraries will be installed in \$HOME/static-libs. We will use PCRE2 10.39 and OpenSSL 1.1.1a.

```
PCRE_PREFIX="$HOME/static-libs/pcre2-10.39"
OPENSSL_PREFIX="$HOME/static-libs/openssl-1.1.1a"
```

Let's build static libraries in static-libs-source:

```
mkdir static-libs-source
cd static-libs-source
```

Download and build PCRE with Unicode properties support:

```
curl --remote-name https://github.com/PhilipHazel/pcre2/releases/download/pcre2-10.39/pcre2-10.39.tar.gz
tar xf pcre2-10.39.tar.gz
cd pcre2-10.39
./configure --prefix="$PCRE_PREFIX" --disable-shared --enable-static --enable-unicode-properties
make
make check
make install
cd ..
```

Download and build OpenSSL:

```
curl --remote-name https://www.openssl.org/source/openssl-1.1.1a.tar.gz
tar xf openssl-1.1.1a.tar.gz
cd openssl-1.1.1a
./Configure --prefix="$OPENSSL_PREFIX" --openssldir="$OPENSSL_PREFIX" --api=1.1.0 no-shared no-capieng no-
make
make test
make install_sw
cd ..
```

Download Zabbix source and build agent:

```
git clone https://git.zabbix.com/scm/zbx/zabbix.git
cd zabbix
```

```
./bootstrap.sh
./configure --sysconfdir=/usr/local/etc/zabbix --enable-agent --enable-ipv6 --with-libpcre2="$PCRE_PREFIX"
make
make install
```

Building agent binaries with static libraries with GnuTLS

GnuTLS depends on the Nettle crypto backend and GMP arithmetic library. Instead of using full GMP library, this guide will use mini-gmp which is included in Nettle.

When building GnuTLS and Nettle, it's recommended to run `make check` after successful building. Even if building was successful, tests sometimes fail. If this is the case, problems should be researched and resolved before continuing.

Let's assume that PCRE, Nettle and GnuTLS static libraries will be installed in `$HOME/static-libs`. We will use PCRE2 10.39, Nettle 3.4.1 and GnuTLS 3.6.5.

```
PCRE_PREFIX="$HOME/static-libs/pcre2-10.39"
NETTLE_PREFIX="$HOME/static-libs/nettle-3.4.1"
GNUTLS_PREFIX="$HOME/static-libs/gnutls-3.6.5"
```

Let's build static libraries in `static-libs-source`:

```
mkdir static-libs-source
cd static-libs-source
```

Download and build Nettle:

```
curl --remote-name https://ftp.gnu.org/gnu/nettle/nettle-3.4.1.tar.gz
tar xf nettle-3.4.1.tar.gz
cd nettle-3.4.1
./configure --prefix="$NETTLE_PREFIX" --enable-static --disable-shared --disable-documentation --disable-a
make
make check
make install
cd ..
```

Download and build GnuTLS:

```
curl --remote-name https://www.gnupg.org/ftp/gcrypt/gnutls/v3.6/gnutls-3.6.5.tar.xz
tar xf gnutls-3.6.5.tar.xz
cd gnutls-3.6.5
PKG_CONFIG_PATH="$NETTLE_PREFIX/lib/pkgconfig" ./configure --prefix="$GNUTLS_PREFIX" --enable-static --dis
make
make check
make install
cd ..
```

Download Zabbix source and build agent:

```
git clone https://git.zabbix.com/scm/zbx/zabbix.git
cd zabbix
./bootstrap.sh
CFLAGS="-Wno-unused-command-line-argument -framework Foundation -framework Security" \
> LIBS="-lgnutls -lhogweed -lnettle" \
> LDFLAGS="-L$GNUTLS_PREFIX/lib -L$NETTLE_PREFIX/lib" \
> ./configure --sysconfdir=/usr/local/etc/zabbix --enable-agent --enable-ipv6 --with-libpcre2="$PCRE_PREFIX"
make
make install
```

4 Installation from packages

Zabbix SIA provides official RPM and DEB packages for:

- Red Hat Enterprise Linux and derivatives
- Debian/Ubuntu/Raspbian
- SUSE Linux Enterprise Server

Package files for yum/dnf, apt, and zypper repositories for various OS distributions are available in the [Zabbix official repository](#).

Some OS distributions (in particular, Debian-based distributions) provide their own Zabbix packages. Note that these packages are **not** supported by Zabbix. Third-party Zabbix packages can be out of date and may lack the latest features and bug fixes. It is recommended to use only the packages from the [Zabbix official repository](#). If you have previously used unofficial Zabbix packages, see notes about [upgrading the Zabbix packages from OS repositories](#).

1 Red Hat Enterprise Linux and derivatives

Overview

Official Zabbix 7.2 packages for Red Hat Enterprise Linux as well as for AlmaLinux, Oracle Linux, Rocky Linux, AmazonLinux, and CentOS are available on [Zabbix website](#).

Attention:

Zabbix packages for Red Hat Enterprise Linux systems are intended only for RHEL systems. Alternative environments, such as [Red Hat Universal Base Image](#), may lack the necessary dependencies and repository access requirements for successful installation. To address such issues, verify compatibility with the target environment and ensure access to required repositories and dependencies before proceeding with Zabbix installation from packages. For more information, see [Known issues](#).

Packages are available with:

- MySQL or PostgreSQL database
- Apache or Nginx web server support

Zabbix agent packages, as well as *Zabbix get* and *Zabbix sender* utilities are also available in Zabbix Official [Repository](#) for the following OS:

- RHEL 7, 8, and 9
- AlmaLinux 8 and 9
- AmazonLinux 2023
- CentOS Stream 8, 9, and 10
- Oracle Linux 8 and 9
- Rocky Linux 8 and 9

The official Zabbix repository provides `fping`, `iksemel` and `libssh2` packages as well. These packages are located in the [third-party](#) directory.

Attention:

The EPEL repository for EL9 also provides Zabbix packages. If both the official Zabbix repository and EPEL repositories are installed, then the Zabbix packages in EPEL **must be** excluded by adding the following clause to the EPEL repo configuration file under `/etc/yum.repos.d/`:

```
[epel]
```

```
...
```

```
excludepkgs=zabbix*
```

See also: [Accidental installation of EPEL Zabbix packages](#)

Notes on installation

See [installation instructions](#) per platform in the download page for:

- installing the repository
- installing server/agent/frontend
- creating initial database, importing initial data
- configuring database for Zabbix server
- configuring PHP for Zabbix frontend
- starting server/agent processes
- configuring Zabbix frontend

If you want to run Zabbix agent as root, see [Running agent as root](#).

Zabbix web service process, which is used for [scheduled report generation](#), requires [Google Chrome browser](#). The browser is not included into packages and has to be installed manually.

Importing data with Timescale DB

With TimescaleDB, in addition to the import command for PostgreSQL, also run:

```
cat /usr/share/zabbix/sql-scripts/postgresql/timescaledb/schema.sql | sudo -u zabbix psql zabbix
```

Warning:

TimescaleDB is supported with Zabbix server only.

SELinux configuration

Zabbix uses socket-based inter-process communication. On systems where SELinux is enabled, it may be required to add SELinux rules to allow Zabbix create/use UNIX domain sockets in the SocketDir directory. Currently, socket files are used by server (alerter, preprocessing, IPMI) and proxy (IPMI). Socket files are persistent, meaning they are present while the process is running.

Having SELinux status enabled in enforcing mode, you need to execute the following commands to enable communication between Zabbix frontend and server:

RHEL 7 and later or AlmaLinux, CentOS Stream, Oracle Linux, Rocky Linux 8 and later:

```
setsebool -P httpd_can_connect_zabbix on
```

If the database is accessible over network (including 'localhost' in case of PostgreSQL), you need to allow Zabbix frontend to connect to the database too:

```
setsebool -P httpd_can_network_connect_db on
```

RHEL prior to 7:

```
setsebool -P httpd_can_network_connect on
```

```
setsebool -P zabbix_can_network on
```

After the frontend and SELinux configuration is done, restart the Apache web server:

```
systemctl restart httpd
```

Optionally, you can download a pre-defined *zabbix-selinux-policy* package from Zabbix repository. This package is provided for all supported OS versions to speed up Zabbix deployment and configuration and prevent users from turning off SELinux because of the configuration complexity.

Attention:

For maximum security level, it is recommended to set custom SELinux settings.

zabbix-selinux-policy package contains a basic default policy for SELinux allowing Zabbix to create and use sockets and enabling HTTPd connection to PostgreSQL (used by frontend). The source *zabbix_policy.te* file contains the following rules:

```
module zabbix_policy 1.2;

require {
    type zabbix_t;
    type zabbix_port_t;
    type zabbix_var_run_t;
    type postgresql_port_t;
    type httpd_t;
    class tcp_socket name_connect;
    class sock_file { create unlink };
    class unix_stream_socket connectto;
}

#===== zabbix_t =====
allow zabbix_t self:unix_stream_socket connectto;
allow zabbix_t zabbix_port_t:tcp_socket name_connect;
allow zabbix_t zabbix_var_run_t:sock_file create;
allow zabbix_t zabbix_var_run_t:sock_file unlink;
allow httpd_t zabbix_port_t:tcp_socket name_connect;

#===== httpd_t =====
allow httpd_t postgresql_port_t:tcp_socket name_connect;
```

Proxy installation

Once the required repository is added, you can install Zabbix proxy by running:

```
dnf install zabbix-proxy-mysql zabbix-sql-scripts
```

Substitute 'mysql' in the commands with 'pgsql' to use PostgreSQL, or with 'sqlite3' to use SQLite3 (proxy only).

The package 'zabbix-sql-scripts' contains database schemas for all supported database management systems for both Zabbix server and Zabbix proxy and will be used for data import.

Creating database

Create a separate database for Zabbix proxy.

Zabbix server and Zabbix proxy cannot use the same database. If they are installed on the same host, the proxy database must have a different name.

Importing data

Import initial schema:

```
cat /usr/share/zabbix/sql-scripts/mysql/proxy.sql | mysql -uzabbix -p zabbix
```

For proxy with PostgreSQL (or SQLite):

```
cat /usr/share/zabbix/sql-scripts/postgresql/proxy.sql | sudo -u zabbix psql zabbix
cat /usr/share/zabbix/sql-scripts/sqlite3/proxy.sql | sqlite3 zabbix.db
```

Configure database for Zabbix proxy

Edit Zabbix proxy configuration file (/etc/zabbix/zabbix_proxy.conf):

```
DBHost=localhost
DBName=zabbix
DBUser=zabbix
DBPassword=<password>
```

In DBName for Zabbix proxy use a separate database from Zabbix server.

In DBPassword use Zabbix database password for MySQL; PostgreSQL user password for PostgreSQL.

Use DBHost= with PostgreSQL. You might want to keep the default setting DBHost=localhost (or an IP address), but this would make PostgreSQL use a network socket for connecting to Zabbix. See [SELinux configuration](#) for instructions.

Starting Zabbix proxy process

To start a Zabbix proxy process and make it start at system boot:

```
systemctl start zabbix-proxy
systemctl enable zabbix-proxy
```

Frontend configuration

A Zabbix proxy does not have a frontend; it communicates with Zabbix server only.

Java gateway installation

It is required to install [Java gateway](#) only if you want to monitor JMX applications. Java gateway is lightweight and does not require a database.

Once the required repository is added, you can install Zabbix Java gateway by running:

```
dnf install zabbix-java-gateway
```

Proceed to [setup](#) for more details on configuring and running Java gateway.

Installing debuginfo packages

Debuginfo package is currently available for RHEL 7.

To enable debuginfo repository, edit /etc/yum.repos.d/zabbix.repo file. Change enabled=0 to enabled=1 for zabbix-debuginfo repository.

```
[zabbix-debuginfo]
name=Zabbix Official Repository debuginfo - $basearch
baseurl=http://repo.zabbix.com/zabbix/7.2/stable/rhel/7/$basearch/debuginfo/
enabled=0
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-ZABBIX-A14FE591
gpgcheck=1
```

This will allow you to install the zabbix-debuginfo package.

```
dnf install zabbix-debuginfo
```

This single package contains debug information for all binary Zabbix components.

2 Debian/Ubuntu/Raspbian

Overview

Official Zabbix 7.2 packages for Debian, Ubuntu, and Raspberry Pi OS (Raspbian) are available on [Zabbix website](#).

Packages are available with either MySQL/PostgreSQL database and Apache/Nginx web server support.

Notes on installation

See the [installation instructions](#) per platform in the download page for:

- installing the repository
- installing server/agent/frontend
- creating initial database, importing initial data
- configuring database for Zabbix server
- configuring PHP for Zabbix frontend
- starting server/agent processes
- configuring Zabbix frontend

If you want to run Zabbix agent as root, see [running agent as root](#).

Zabbix web service process, which is used for [scheduled report generation](#), requires [Google Chrome browser](#). The browser is not included into packages and has to be installed manually.

Importing data with Timescale DB

With TimescaleDB, in addition to the import command for PostgreSQL, also run:

```
cat /usr/share/zabbix/sql-scripts/postgresql/timescaledb/schema.sql | sudo -u zabbix psql zabbix
```

Warning:

TimescaleDB is supported with Zabbix server only.

SELinux configuration

See [SELinux configuration](#) for RHEL.

After the frontend and SELinux configuration is done, restart the Apache web server:

```
systemctl restart apache2
```

Proxy installation

Once the required repository is added, you can install Zabbix proxy by running:

```
apt install zabbix-proxy-mysql zabbix-sql-scripts
```

Substitute 'mysql' in the command with 'pgsql' to use PostgreSQL, or with 'sqlite3' to use SQLite3.

The package 'zabbix-sql-scripts' contains database schemas for all supported database management systems for both Zabbix server and Zabbix proxy and will be used for data import.

Creating database

Create a separate database for Zabbix proxy.

Zabbix server and Zabbix proxy cannot use the same database. If they are installed on the same host, the proxy database must have a different name.

Importing data

Import initial schema:

```
cat /usr/share/zabbix/sql-scripts/mysql/proxy.sql | mysql -uzabbix -p zabbix
```

For proxy with PostgreSQL (or SQLite):

```
cat /usr/share/zabbix/sql-scripts/postgresql/proxy.sql | sudo -u zabbix psql zabbix
cat /usr/share/zabbix/sql-scripts/sqlite3/proxy.sql | sqlite3 zabbix.db
```

Configure database for Zabbix proxy

Edit Zabbix proxy configuration file (/etc/zabbix/zabbix_proxy.conf):

```
DBHost=localhost
DBName=zabbix
DBUser=zabbix
DBPassword=<password>
```

In DBName for Zabbix proxy use a separate database from Zabbix server.

In DBPassword use Zabbix database password for MySQL; PostgreSQL user password for PostgreSQL.

Use DBHost= with PostgreSQL. You might want to keep the default setting DBHost=localhost (or an IP address), but this would make PostgreSQL use a network socket for connecting to Zabbix. Refer to the [respective section](#) for RHEL for instructions.

Starting Zabbix proxy process

To start a Zabbix proxy process and make it start at system boot:

```
systemctl restart zabbix-proxy
systemctl enable zabbix-proxy
```

Frontend configuration

A Zabbix proxy does not have a frontend; it communicates with Zabbix server only.

Java gateway installation

It is required to install [Java gateway](#) only if you want to monitor JMX applications. Java gateway is lightweight and does not require a database.

Once the required repository is added, you can install Zabbix Java gateway by running:

```
apt install zabbix-java-gateway
```

Proceed to [setup](#) for more details on configuring and running Java gateway.

3 SUSE Linux Enterprise Server

Overview

Official Zabbix 7.2 packages for SUSE Linux Enterprise Server are available on [Zabbix website](#).

Zabbix agent packages and utilities *Zabbix get* and *Zabbix sender* are available in Zabbix Official Repository for [SLES 15 \(SP4 and newer\)](#) and [SLES 12 \(SP4 and newer\)](#).

Please note that SLES 12 can be used only for Zabbix proxy and the following features are not available:

- *Verify CA encryption mode* with MySQL does not work due to older MySQL libraries.
- *SSH checks* - due to the older libssh version.

Adding Zabbix repository

Install the repository configuration package. This package contains yum (software package manager) configuration files.

SLES 15:

```
rpm -Uvh --nosignature https://repo.zabbix.com/zabbix/7.2/release/sles/15/noarch/zabbix-release-latest.sles15.noarch.rpm
zypper --gpg-auto-import-keys refresh 'Zabbix Official Repository'
```

SLES 12 (proxy only):

```
rpm -Uvh --nosignature https://repo.zabbix.com/zabbix/7.2/release/sles/12/noarch/zabbix-release-latest.sles12.noarch.rpm
zypper --gpg-auto-import-keys refresh 'Zabbix Official Repository'
```

Please note that Zabbix web service process, which is used for [scheduled report generation](#), requires [Google Chrome browser](#). The browser is not included into packages and has to be installed manually.

Server/frontend/agent installation

To install Zabbix server/frontend/agent with PHP 8, Apache and MySQL support, run:

```
zypper install zabbix-server-mysql zabbix-web-mysql zabbix-apache-conf-php8 zabbix-agent
```

Substitute component names in this command as needed:

- **For Nginx:** use zabbix-nginx-conf-php8 instead of zabbix-apache-conf-php8. See also: [Nginx setup for Zabbix on SLES 15](#).
- **For PostgreSQL:** use zabbix-server-pgsql instead of zabbix-server-mysql; use zabbix-web-pgsql instead of zabbix-web-mysql.

- **For Zabbix agent 2** (only SLES 15): use `zabbix-agent2` instead of or in addition to `zabbix-agent`.

To install Zabbix proxy with MySQL support:

```
zypper install zabbix-proxy-mysql zabbix-sql-scripts
```

For PostgreSQL, use `zabbix-proxy-pgsql` instead of `zabbix-proxy-mysql`.

For SQLite3, use `zabbix-proxy-sqlite3` instead of `zabbix-proxy-mysql`.

The package 'zabbix-sql-scripts' contains database schemas for all supported database management systems for both Zabbix server and Zabbix proxy and will be used for data import.

Creating database

Zabbix **server** and **proxy** daemons require a database. Zabbix **agent** does not need a database.

To create a database, follow the instructions for **MySQL** or **PostgreSQL**. An SQLite3 database (supported for Zabbix proxy only) will be created automatically and does not require additional installation steps.

Warning:

Separate databases are required for Zabbix server and Zabbix proxy; they cannot share the same database. If a server and a proxy are installed on the same host, their databases must be created with different names!

Importing data

Now import initial schema and data for the **server** with MySQL:

```
zcat /usr/share/packages/zabbix/sql-scripts/mysql/create.sql.gz | mysql -uzabbix -p zabbix
```

You will be prompted to enter your newly created database password.

With PostgreSQL:

```
zcat /usr/share/packages/zabbix/sql-scripts/postgresql/create.sql.gz | sudo -u zabbix psql zabbix
```

With TimescaleDB, in addition to the previous command, also run:

```
zcat /usr/share/packages/zabbix/sql-scripts/postgresql/timescaledb/schema.sql.gz | sudo -u <username> psql
```

Warning:

TimescaleDB is supported with Zabbix server only.

For proxy, import initial schema:

```
zcat /usr/share/packages/zabbix/sql-scripts/mysql/schema.sql.gz | mysql -uzabbix -p zabbix
```

For proxy with PostgreSQL:

```
zcat /usr/share/packages/zabbix/sql-scripts/postgresql/schema.sql.gz | sudo -u zabbix psql zabbix
```

Configure database for Zabbix server/proxy

Edit Zabbix server configuration file (`/etc/zabbix/zabbix_server.conf`) and, if required, Zabbix proxy configuration file (`/etc/zabbix/zabbix_proxy.conf`) for their respective databases. For example:

```
DBHost=localhost
DBName=zabbix
DBUser=zabbix
DBPassword=<password>
```

In `DBPassword` use Zabbix database password for MySQL; PostgreSQL user password for PostgreSQL.

Use `DBHost=` with PostgreSQL. You might want to keep the default setting `DBHost=localhost` (or an IP address), but this would make PostgreSQL use a network socket for connecting to Zabbix.

Zabbix frontend configuration

Depending on the web server used (Apache/Nginx), edit the corresponding configuration file for Zabbix frontend. While some PHP settings may already be configured, it's essential that you uncomment the `date.timezone` setting and specify the appropriate [timezone](#) setting that suits your requirements.

- For Apache the configuration file is located in `/etc/apache2/conf.d/zabbix.conf`.

```

php_value max_execution_time 300
php_value memory_limit 128M
php_value post_max_size 16M
php_value upload_max_filesize 2M
php_value max_input_time 300
php_value max_input_vars 10000
php_value always_populate_raw_post_data -1
# php_value date.timezone Europe/Riga

```

- The zabbix-nginx-conf package installs a separate Nginx server for Zabbix frontend. Its configuration file is located in `/etc/nginx/conf.d/zabbix.conf`. For Zabbix frontend to work, it's necessary to uncomment and set `listen` and/or `server_name` directives.

```

# listen 80;
# server_name example.com;

```

- Zabbix uses its own dedicated php-fpm connection pool with Nginx:

Its configuration file is located in `/etc/php8/fpm/php-fpm.d/zabbix.conf` (the path may vary slightly depending on the service pack).

```

php_value[max_execution_time] = 300
php_value[memory_limit] = 128M
php_value[post_max_size] = 16M
php_value[upload_max_filesize] = 2M
php_value[max_input_time] = 300
php_value[max_input_vars] = 10000
; php_value[date.timezone] = Europe/Riga

```

Now you are ready to proceed with **frontend installation steps** that will allow you to access your newly installed Zabbix.

Note that a Zabbix proxy does not have a frontend; it communicates with Zabbix server only.

Starting Zabbix server/agent process

Start Zabbix server and agent processes and make it start at system boot.

With Apache web server:

```

systemctl restart zabbix-server zabbix-agent apache2 php-fpm
systemctl enable zabbix-server zabbix-agent apache2 php-fpm

```

For Nginx, substitute `apache2` with `nginx`.

Installing debuginfo packages

To enable debuginfo repository edit `/etc/zypp/repos.d/zabbix.repo` file. Change `enabled=0` to `enabled=1` for `zabbix-debuginfo` repository.

```

[zabbix-debuginfo]
name=Zabbix Official Repository debuginfo
type=rpm-md
baseurl=https://repo.zabbix.com/zabbix/7.2/stable/sles/15/x86_64/debuginfo/
gpgcheck=1
gpgkey=https://repo.zabbix.com/zabbix/7.2/stable/sles/15/x86_64/debuginfo/repokey/repomd.xml.key
enabled=0
update=1

```

This will allow you to install `zabbix-<component>-debuginfo` packages.

4 Windows agent installation from MSI

Overview

Zabbix agent can be installed on Windows using 32-bit or 64-bit MSI installer packages, available for [download](#).

Minimum OS requirements for MSI installation are:

- **For Zabbix agent:** Windows XP (64-bit) or Windows Server 2003
- **For Zabbix agent 2:** Windows 10 (32-bit) or Windows Server 2016

32-bit packages cannot be installed on 64-bit systems.

Packages include:

- TLS support (TLS configuration is optional)
- **Zabbix get** and **Zabbix sender** utilities (can be installed alongside Zabbix agent/agent 2 or separately)

Attention:

Zabbix agent 2 packages do not include loadable plugins (MongoDB, PostgreSQL, MSSQL), which need to be **downloaded and installed** separately.

Installation can be done using the **Setup Wizard** or the **command line**.

Although installation using MSI packages is fully supported, installing at least **Microsoft .NET Framework 2** is recommended for proper error handling.

Attention:

It is recommended to use the default installation location provided by the installer. Using a custom location without the necessary permissions may compromise the security of the installation.

Installation from Setup Wizard

The following installation steps apply to both Zabbix agent and Zabbix agent 2.

1. Double-click the downloaded MSI file to start the installation:

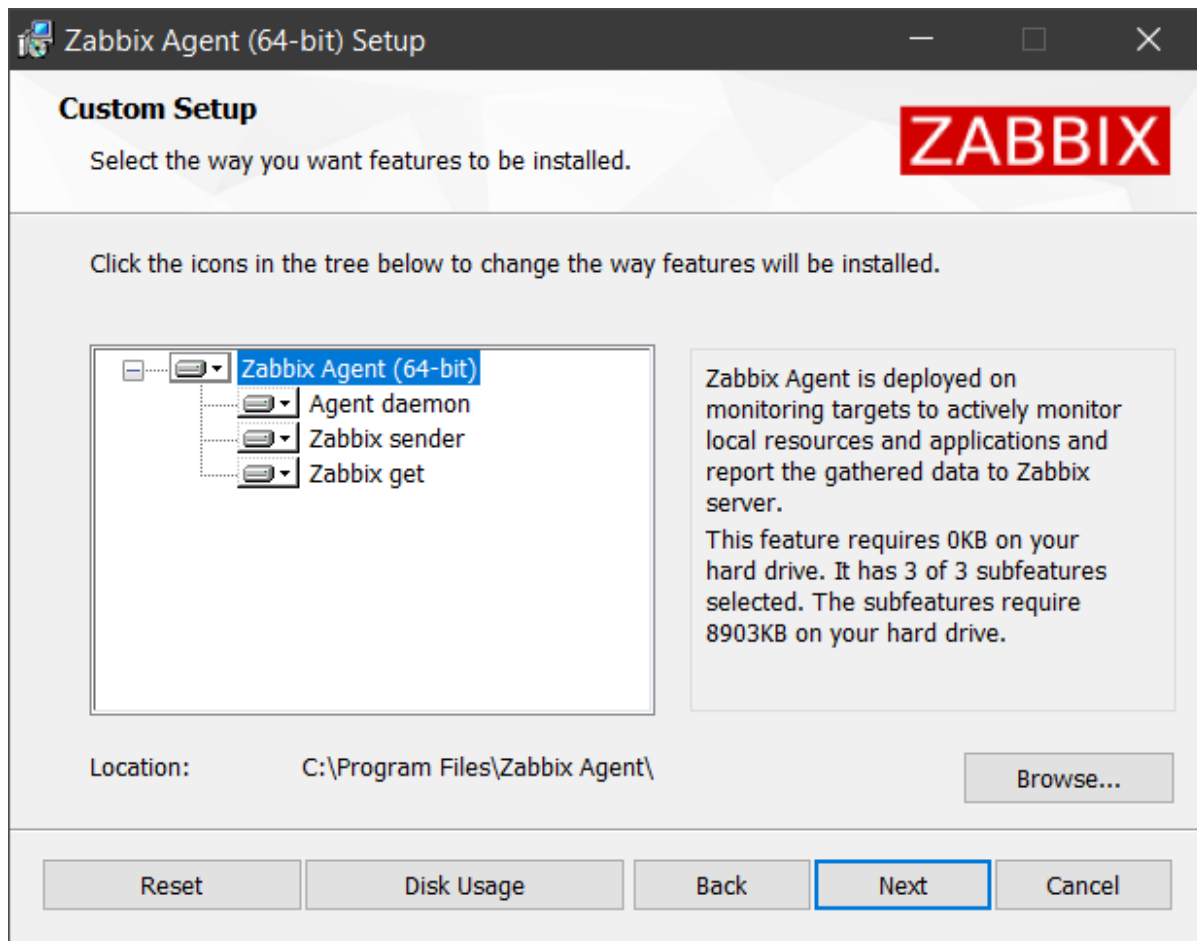

2. Accept the End-User License Agreement:

3. Select the Zabbix components (**Agent daemon**, **Zabbix sender**, **Zabbix get**) to be installed:

Attention:

It is recommended to use the default installation location provided by the installer. Using a custom location without the necessary permissions may compromise the security of the installation.

4. Configure the following parameters. Their values will be set in the Zabbix agent configuration file:

| Parameter | Description |
|--|--|
| <i>Host name</i> | The host name of the machine where Zabbix agent is being installed. Sets the Hostname parameter. |
| <i>Zabbix server IP/DNS</i> | A list of comma-delimited IP addresses, optionally in CIDR notation, or DNS names of Zabbix servers or Zabbix proxies. This parameter is mandatory . Sets the Server parameter. |
| <i>Agent listen port</i> | The agent will listen on this port for connections from the server. Sets the ListenPort parameter. |
| <i>Server or Proxy for active checks</i> | The Zabbix server/proxy address or cluster configuration to get active checks from. The server/proxy address is an IP address or DNS name and optional port separated by colon. Sets the ServerActive parameter. |
| <i>Enable PSK</i> | Mark the checkbox to enable TLS support using pre-shared keys . Sets the TLSCConnect and TLSAccept parameters to psk. |
| <i>Add agent location to the PATH</i> | Mark the checkbox to add Zabbix agent location to the system PATH variable. |

Note:

If an existing Zabbix agent is detected, the parameter values from its configuration file will be displayed. Additionally the existing configuration file will be renamed during installation, and a new configuration file will be created.

Zabbix Agent service configuration

Please enter the information for configure Zabbix Agent

Host name:

Zabbix server IP/DNS:

Agent listen port:

Server or Proxy for active checks:

☒ Enable PSK

☒ Add agent location to the PATH

* The previous configuration file will be renamed to zabbix_agentd.conf.old.6.0.0.2400

Back

Next

Cancel

5. Configure PSK parameters if you marked the *Enable PSK* checkbox in the previous step. These parameters will also be set in the Zabbix agent configuration file:

| Parameter | Description |
|--------------------------------|--|
| <i>Pre-shared key identity</i> | The pre-shared key identity string. Sets the TLSPSKIdentity parameter. |
| <i>Pre-shared key value</i> | The pre-shared key string value. Creates the <code>psk.key</code> file containing the key and sets the TLSPSKFile parameter to the key location (default: <code>C:\Program Files\Zabbix Agent\psk.key</code>). It is recommended to restrict access to the pre-shared key file by adjusting the file's security settings so that only Zabbix agent (or the user running the agent) can read it. |

Zabbix Agent (64-bit) PSK Setup

Zabbix Agent pre-shared key configuration

Please enter the PSK information for configure Zabbix Agent

Pre-shared key identity:

PSK 001

Pre-shared key value:

1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952

Please, set minimum required permission to access the psk.key file

Back Next Cancel

6. Click *Install* to begin the installation.

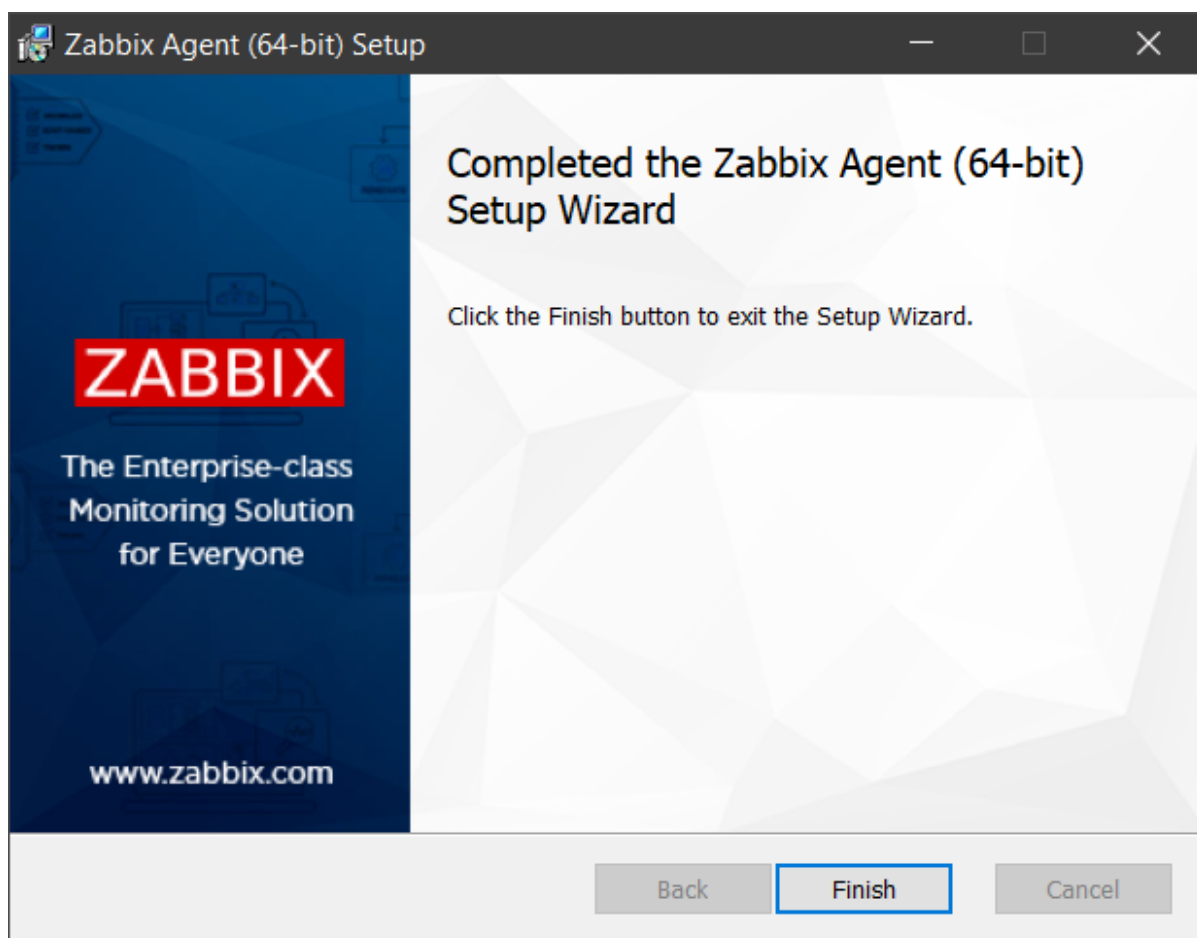

All selected Zabbix components and the Zabbix agent configuration file will be installed in your specified location (default: C:\Program Files\Zabbix Agent). The same applies to Zabbix agent 2, except additional configuration files for its **built-in plugins** will be installed in the zabbix_agent2.d\plugins.d subfolder.

Additionally, zabbix_agentd.exe (or zabbix_agent2.exe) will be set up as a Windows service with delayed automatic startup (or automatic startup on Windows versions before Windows Vista/Server 2008).

If a different version of Zabbix agent is running during installation, you will be prompted to choose either to close the application and try restarting it or leave it open, in which case a reboot will be required.

7. Click the *Finish* button to exit the Setup Wizard.

Installation from command line

Zabbix agent can be installed from the command line by running the MSI installer with `msiexec`. For example:

```
msiexec.exe /l*v "C:\package.log" /i "C:\zabbix_agent-7.2.0-windows-amd64-openssl.msi" /qn+ SERVER=192.0.2
```

This method allows for unattended installations and custom configurations using parameters.

Supported parameters

Zabbix agent MSI installer packages support the following parameters for both Zabbix agent and Zabbix agent 2.

Note:

Zabbix agent/agent2 parameters are set in the configuration file during installation. Click a parameter name to view its detailed description and configuration examples on the [Zabbix agent \(Windows\)](#) page. For Zabbix agent 2, refer to the [Zabbix agent 2 \(Windows\)](#) page.

| Parameter | Description |
|------------------------|--|
| ADDDEFAULT | A list of comma-delimited components to install in their default configuration. For more information, see ADDDEFAULT property . Possible values: AgentProgram, GetProgram, SenderProgram, ALL Example: ADDDEFAULT=AgentProgram,GetProgram |
| ADDLOCAL | A list of comma-delimited components to install locally. For more information, see ADDLOCAL property . Possible values: AgentProgram, GetProgram, SenderProgram, ALL Example: ADDLOCAL=AgentProgram,SenderProgram |
| ALLOWDENYKEY | A list of semicolon-delimited AllowKey or DenyKey parameters to restrict Zabbix agent checks . If necessary, use a backslash to escape the delimiter (\;). Sets the AllowKey and DenyKey parameters in the agent configuration file. Example: ALLOWDENYKEY="AllowKey=system.run[type C:\Windows\System32\drivers\etc\hosts];DenyKey=system.run[*]" |
| CONF | The full pathname to a custom configuration file for Zabbix agent. During installation, this file will fully replace the contents of the new or existing agent configuration file. The file must contain at least the Server and LogFile parameters. Example: CONF="C:\full\path\to\example.conf" |
| ENABLEPATH | Use ENABLEPATH=1 to add Zabbix agent location to the system PATH variable. |
| ENABLEPERSISTENTBUFFER | Zabbix agent 2 only. Enable the usage of local persistent storage for active items. |
| HOSTINTERFACE | An optional parameter that defines the host interface. |
| HOSTMETADATA | An optional parameter that defines the host metadata. |
| HOSTMETADATAITEM | An optional parameter that defines an item used for getting the host metadata. |
| HOSTNAME | An optional parameter that defines the hostname. |
| INCLUDE | A list of semicolon-delimited individual files or all files in a directory to include in the Zabbix agent configuration file. |
| INSTALLFOLDER | The full pathname to a folder where Zabbix components and the Zabbix agent configuration file will be installed. For Zabbix agent 2, additional configuration files for built-in plugins will be installed in the zabbix_agent2.d\plugins.d subfolder. Example: INSTALLFOLDER="C:\Program Files\Zabbix Agent" |
| LISTENIP | A list of comma-delimited IP addresses that the agent should listen on. |
| LISTENPORT | The agent will listen on this port for connections from the server. |
| LOGFILE | The name of the Zabbix agent log file. |
| LOGTYPE | The type of the log output. |
| NONMSICONFNAME | The full pathname to a custom configuration file for Zabbix agent. During installation, any valid agent configuration parameters present in this file (limited to those listed in this table) will replace the corresponding parameters in the new or existing agent configuration file. The file must contain at least the Server parameter. Example: NONMSICONFNAME="C:\full\path\to\example.conf" |
| PERSISTENTBUFFERFILE | Zabbix agent 2 only. The file where Zabbix agent 2 should keep the SQLite database. |
| PERSISTENTBUFFERPERIOD | Zabbix agent 2 only. The time period for which data should be stored when there is no connection to the server or proxy. |
| SERVER | A list of comma-delimited IP addresses, optionally in CIDR notation, or DNS names of Zabbix servers or Zabbix proxies. This parameter is mandatory . |
| SERVERACTIVE | The Zabbix server/proxy address or cluster configuration to get active checks from. |
| SKIP | Use SKIP=fw to prevent the MSI installer from adding a Windows Firewall exception rule for Zabbix agent. |

| Parameter | Description |
|----------------------|---|
| STARTUPTYPE | Startup type of the Zabbix agent service. Possible values: automatic - start the service automatically at Windows startup; delayed - (default) delay starting the service after the automatically started services have completed startup (available on Windows Vista/Server 2008 and later versions); manual - start the service manually (by a user or application); disabled - disable the service so that it cannot be started by a user or application. Example: STARTUPTYPE=disabled |
| STATUSPORT | Zabbix agent 2 only. If set, the agent will listen on this port for HTTP status requests (http://localhost:<port>/status). |
| TIMEOUT | Specifies how long to wait (in seconds) for establishing connection and exchanging data with Zabbix proxy or server. |
| TLSACCEPT | The incoming connections to accept (used for passive checks). If set to psk, then TLSCONNECT will also be set to psk (unless specified otherwise). |
| TLSCAFILE | The full pathname of a file containing the top-level CA(s) certificates for peer certificate verification. |
| TLSCERTFILE | The full pathname of a file containing the agent certificate or certificate chain. |
| TLSCONNECT | How the agent should connect to Zabbix server or proxy (used for active checks). If set to psk, then TLSACCEPT will also be set to psk (unless specified otherwise). |
| TLSCRLFILE | The full pathname of a file containing revoked certificates. |
| TLSCKEYFILE | The full pathname of a file containing the Zabbix agent private key. |
| TLSPSKFILE | The full pathname of a file containing the Zabbix agent pre-shared key. If both TLSPSKFILE and TLSPSKVALUE are set, the value of TLSPSKVALUE will be written into the file specified in TLSPSKFILE. It is recommended to restrict access to the pre-shared key file by adjusting the file's security settings so that only Zabbix agent (or the user running the agent) can read it. |
| TLSPSKIDENTITY | The pre-shared key identity string. |
| TLSPSKVALUE | The pre-shared key string value. If both TLSPSKFILE and TLSPSKVALUE are set, the value of TLSPSKVALUE will be written into the file specified in TLSPSKFILE. Example: TLSPSKVALUE=1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952 |
| TLSSERVERCERTISSUER | The allowed server (proxy) certificate issuer. |
| TLSSERVERCERTSUBJECT | The allowed server (proxy) certificate subject. |

Examples

The following example installs Zabbix agent with custom configuration. It also enables TLS support **using pre-shared keys**.

```
mkdir "C:\Program Files\Zabbix Agent" 2>nul
msiexec.exe /l*v "C:\package.log" /i "C:\zabbix_agent-7.2.0-windows-amd64-openssl.msi" /qn+^
SERVER=192.0.2.0^
INSTALLFOLDER="C:\Program Files\Zabbix Agent"^
HOSTNAME=LAPTOP-IKP7S51S^
TLSACCEPT=psk^
TLSCONNECT=psk^
TLSPSKIDENTITY="PSK 001"^
TLSPSKFILE="C:\Program Files\Zabbix Agent\psk.key"^
TLSPSKVALUE=1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952^
ENABLEPATH=1^
ALLOWDENYKEY="AllowKey=system.run[type C:\Windows\System32\drivers\etc\hosts];DenyKey=system.run[*]"
```

The following example installs a newer version of Zabbix agent and uses a custom configuration file to replace specific parameters (e.g., Hostname=LAPTOP-IKP7S51S, DESKTOP-X9F4A2B) in the existing agent configuration file.

```
msiexec.exe /l*v "C:\package.log" /i "C:\zabbix_agent-7.2.4-windows-amd64-openssl.msi" /qn+ NONMSICONFNAME
```

Zabbix agent 2 loadable plugins

Zabbix agent 2 **loadable plugins** can be installed on Windows using 64-bit MSI installer packages, available for [download](#).

Minimum OS requirements for MSI installation are Windows 10 (64-bit) or Windows Server 2016.

Packages include:

- MongoDB plugin
- PostgreSQL plugin
- MSSQL plugin

Packages do not include the **Ember+ plugin**, which is currently only available to be built from source (for both Unix and Windows).

Attention:

Before installing a plugin, check its README file. It may contain additional requirements and installation instructions specific to the plugin.

Similarly to Zabbix agent/agent2, loadable plugins can be installed using the Setup Wizard or the command line.

Installation from Setup Wizard

1. Double-click the downloaded MSI file to start the installation.
2. Accept the End-User License Agreement.
3. Select the Zabbix agent 2 loadable plugins (**MongoDB plugin**, **PostgreSQL plugin**, **MSSQL plugin**) to be installed.

Attention:

It is recommended to use the default installation location provided by the installer. Using a custom location without the necessary permissions may compromise the security of the installation.

4. Click *Install* to begin the installation.

All selected Zabbix agent 2 loadable plugins will be installed in your specified location (default: C:\Program Files\Zabbix Agent 2), with their configuration files installed in the zabbix_agent2.d subfolder.

5. Click the *Finish* button to exit the Setup Wizard.

Installation from command line

Zabbix agent 2 loadable plugins can be installed from the command line by running the MSI installer with **msiexec**. For example:

```
msiexec.exe /l*v "C:\package.log" /i "C:\zabbix_agent2_plugins-7.0.0-windows-amd64.msi" /qn+
```

Zabbix agent 2 loadable plugin MSI installer packages support the following parameters.

| Parameter | Description |
|---------------|---|
| ADDDEFAULT | A list of comma-delimited components to install in their default configuration. For more information, see ADDDEFAULT property . Possible values: MongoddbPlugin, PostgresqlPlugin, MssqlPlugin, ALL Example: ADDDEFAULT=MongoddbPlugin,PostgresqlPlugin |
| ADDLOCAL | A list of comma-delimited components to install locally. For more information, see ADDLOCAL property . Possible values: MongoddbPlugin, PostgresqlPlugin, MssqlPlugin, ALL Example: ADDLOCAL=MongoddbPlugin,MssqlPlugin |
| INSTALLFOLDER | The full pathname to a folder where Zabbix components will be installed, with their configuration files installed in the zabbix_agent2.d subfolder. Example: INSTALLFOLDER="C:\Program Files\Zabbix Agent 2" |

5 Mac OS agent installation from PKG

Overview

Zabbix Mac OS agent can be installed from PKG installer packages available for [download](#). Versions with or without encryption are available.

Installing agent

The agent can be installed using the graphical user interface or from the command line, for example:

```
sudo installer -pkg zabbix_agent-7.2.0-macos-amd64-openssl.pkg -target /
```

Make sure to use the correct Zabbix package version in the command. It must match the name of the downloaded package.

Running agent

The agent will start automatically after installation or restart.

You may edit the configuration file at /usr/local/etc/zabbix/zabbix_agentd.conf if necessary.

To start the agent manually, you may run:

```
sudo systemctl start com.zabbix.zabbix_agentd
```

To stop the agent manually:

```
sudo systemctl stop com.zabbix.zabbix_agentd
```

During upgrade, the existing configuration file is not overwritten. Instead a new `zabbix_agentd.conf.NEW` file is created to be used for reviewing and updating the existing configuration file, if necessary. Remember to restart the agent after manual changes to the configuration file.

Troubleshooting and removing agent

This section lists some useful commands that can be used for troubleshooting and removing Zabbix agent installation.

See if Zabbix agent is running:

```
ps aux | grep zabbix_agentd
```

See if Zabbix agent has been installed from packages:

```
pkgutil --pkgs | grep zabbix
com.zabbix.pkg.ZabbixAgent
```

See the files that were installed from the installer package (note that the initial / is not displayed in this view):

```
pkgutil --only-files --files com.zabbix.pkg.ZabbixAgent
Library/LaunchDaemons/com.zabbix.zabbix_agentd.plist
usr/local/bin/zabbix_get
usr/local/bin/zabbix_sender
usr/local/etc/zabbix/zabbix_agentd/userparameter_examples.conf.NEW
usr/local/etc/zabbix/zabbix_agentd/userparameter_mysql.conf.NEW
usr/local/etc/zabbix/zabbix_agentd.conf.NEW
usr/local/sbin/zabbix_agentd
```

Stop Zabbix agent if it was launched with `launchctl`:

```
sudo launchctl unload /Library/LaunchDaemons/com.zabbix.zabbix_agentd.plist
```

Remove files (including configuration and logs) that were installed with installer package:

```
sudo rm -f /Library/LaunchDaemons/com.zabbix.zabbix_agentd.plist
sudo rm -f /usr/local/sbin/zabbix_agentd
sudo rm -f /usr/local/bin/zabbix_get
sudo rm -f /usr/local/bin/zabbix_sender
sudo rm -rf /usr/local/etc/zabbix
sudo rm -rf /var/log/zabbix
```

Forget that Zabbix agent has been installed:

```
sudo pkgutil --forget com.zabbix.pkg.ZabbixAgent
```

6 Unstable releases

Overview

The instructions below are for enabling unstable Zabbix release repositories (disabled by default) used for minor Zabbix version release candidates.

First, install or update to the latest `zabbix-release` package. To enable rc packages on your system do the following:

Red Hat Enterprise Linux

Open the `/etc/yum.repos.d/zabbix.repo` file and set `enabled=1` for the `zabbix-unstable` repo.

```
[zabbix-unstable]
name=Zabbix Official Repository (unstable) - $basearch
baseurl=https://repo.zabbix.com/zabbix/7.2/unstable/rhel/8/$basearch/
enabled=1
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-ZABBIX-A14FE591
```

Debian/Ubuntu

Open the `/etc/apt/sources.list.d/zabbix.list` and uncomment "Zabbix unstable repository".

```
#### Zabbix unstable repository
deb https://repo.zabbix.com/zabbix/7.2/unstable/debian bullseye main
deb-src https://repo.zabbix.com/zabbix/7.2/unstable/debian bullseye main
```

SUSE

Open the `/etc/zypp/repos.d/zabbix.repo` file and set `enable=1` for the `zabbix-unstable` repo.

```
[zabbix-unstable]
name=Zabbix Official Repository
type=rpm-md
baseurl=https://repo.zabbix.com/zabbix/7.2/unstable/sles/15/x86_64/
gpgcheck=1
gpgkey=https://repo.zabbix.com/zabbix/7.2/unstable/sles/15/x86_64/repokey/zabbix.repokey
enabled=1
update=1
```

5 Installation from containers

Overview This section describes how to deploy Zabbix with [Docker](#) or [Docker Compose](#).

Zabbix officially provides:

- Separate Docker images for each Zabbix component to run as portable and self-sufficient containers.
- Compose files for defining and running multi-container Zabbix components in Docker.

Attention:

Since Zabbix 6.0, deterministic triggers need to be created during the installation. If binary logging is enabled for MySQL/MariaDB, this requires superuser privileges or setting the variable/configuration parameter `log_bin_trust_function_creators = 1`. See [Database creation scripts](#) for instructions how to set the variable. Note that if executing from a console, the variable will only be set temporarily and will be dropped when a Docker is restarted. In this case, keep your SQL service running, only stop `zabbix-server` service by running `'docker compose down zabbix-server'` and then `'docker compose up -d zabbix-server'`. Alternatively, you can set this variable in the configuration file.

Source files

Docker file sources are stored in the Zabbix [official repository](#) on GitHub, where you can follow latest file changes or fork the project to make your own images.

Docker Zabbix provides images based on a variety of OS base images. To get the list of supported base operating system images for a specific Zabbix component, see the component's description in [Docker Hub](#). All Zabbix images are configured to rebuild latest images if base images are updated.

Installation

To get Zabbix component image, run:

```
docker pull zabbix/zabbix-server-mysql
```

Replace `zabbix/zabbix-server-mysql` with the name of the required docker repository.

This command will pull the latest stable Zabbix component version based on the Alpine Linux OS. You can append **tags** to the repository name to get an image based on another operating system or of the specific Zabbix major or minor version.

The following repositories are available in Docker Hub:

| Component | Docker repository |
|-------------------------|--|
| Zabbix agent | zabbix/zabbix-agent |
| Zabbix server | |
| with MySQL support | zabbix/zabbix-server-mysql |
| with PostgreSQL support | zabbix/zabbix-server-pgsql |

| Component | Docker repository |
|---|--|
| <i>Zabbix</i> <i>web</i> <i>inter-</i> <i>face</i> | based on Apache2 web server with MySQL support zabbix/zabbix-web-apache-mysql based on Apache2 web server with PostgreSQL support zabbix/zabbix-web-apache-pgsql based on Nginx web server with MySQL support zabbix/zabbix-web-nginx-mysql based on Nginx web server with PostgreSQL support zabbix/zabbix-web-nginx-pgsql |
| <i>Zabbix</i> <i>proxy</i> | with SQLite3 support zabbix/zabbix-proxy-sqlite3 with MySQL support zabbix/zabbix-proxy-mysql |
| <i>Zabbix</i> <i>Java</i> <i>gate-</i> <i>way</i> | zabbix/zabbix-java-gateway |

Note:

SNMP trap support is provided in a separate repository [zabbix/zabbix-snmptraps](#). It can be linked with Zabbix server and Zabbix proxy.

Tags

Official Zabbix component images may contain the following tags:

| Tag | Description | Example |
|-----------------|---|--------------------------------|
| latest | The latest stable version of a Zabbix component based on Alpine Linux image. | zabbix-agent:latest |
| <OS>-trunk | The latest nightly build of the Zabbix version that is currently being developed on a specific operating system. <OS> - the base operating system. Supported values: <i>alpine</i> - Alpine Linux; <i>ltsc2019</i> - Windows 10 LTSC 2019 (agent only); <i>ol</i> - Oracle Linux; <i>ltsc2022</i> - Windows 11 LTSC 2022 (agent only); <i>ubuntu</i> - Ubuntu | zabbix agent:ubuntu-trunk |
| <OS>-latest | The latest stable version of a Zabbix component on a specific operating system. <OS> - the base operating system. Supported values: <i>alpine</i> - Alpine Linux; <i>ltsc2019</i> - Windows 10 LTSC 2019 (agent only); <i>ol</i> - Oracle Linux; <i>ltsc2022</i> - Windows 11 LTSC 2022 (agent only); <i>ubuntu</i> - Ubuntu | zabbix-agent:ol-latest |
| <OS>-X.X-latest | The latest minor version of a Zabbix component of a specific major version and operating system. <OS> - the base operating system. Supported values: <i>alpine</i> - Alpine Linux; <i>ltsc2019</i> - Windows 10 LTSC 2019 (agent only); <i>ol</i> - Oracle Linux; <i>ltsc2022</i> - Windows 11 LTSC 2022 (agent only); <i>ubuntu</i> - Ubuntu X.X - the major Zabbix version (i.e. 6.0, 7.0, 7.2). | zabbix-agent:alpine-7.2-latest |

| Tag | Description | Example |
|------------|---|---------------------------|
| <OS>-X.X.* | The latest minor version of a Zabbix component of a specific major version and operating system. <OS> - the base operating system. Supported values: <i>alpine</i> - Alpine Linux; <i>ltsc2019</i> - Windows 10 LTSC 2019 (agent only); <i>ol</i> - Oracle Linux; <i>ltsc2022</i> - Windows 11 LTSC 2022 (agent only); <i>ubuntu</i> - Ubuntu X.X - the major Zabbix version (i.e. 6.0, 7.0, 7.2). * - the Zabbix minor version | zabbix-agent:alpine-7.2.1 |

Initial configuration

After downloading the images, start the containers by executing `docker run` command followed by additional arguments to specify required **environment variables** and/or **mount points**. Some **configuration examples** are provided below.

Note:

To enable communication between Zabbix components, some ports, such as 10051/TCP for Zabbix server (trapper), 10050/TCP for Zabbix agent, 162/UDP for SNMP traps and 80/TCP for Zabbix web interface will be exposed to a host machine. Full list of default ports used by Zabbix components is available on the **Requirements** page. For Zabbix server and agent the default port can be changed by setting `ZBX_LISTENPORT` **environment variable**.

Environment variables

All Zabbix component images provide environment variables to control configuration. Supported environment variables are listed in the **component repository**.

These environment variables are options from Zabbix configuration files, but with different naming method. For example, `ZBX_LOGSLOWQUERIES` is equal to `LogSlowQueries` from Zabbix **server** or Zabbix **proxy** configuration files.

Attention:

Some configuration options (e.g., `PIDFile` and `LogType`) cannot be changed.

The following environment variables are specific to Docker components and do not exist in Zabbix configuration files:

| Variable | Components | Default value | Description |
|-------------------|----------------------------------|---|---|
| DB_SERVER_HOST | Server Proxy Web interface | mysql-server for MySQL postgres-server for PostgreSQL | IP or DNS name of MySQL or PostgreSQL server. |
| DB_SERVER_PORT | Server Proxy Web interface | 3306 for MySQL 5432 for PostgreSQL | Port of MySQL or PostgreSQL server. |
| MYSQL_USER | Server Proxy Web-interface | zabbix | MySQL database user. |
| MYSQL_PASSWORD | Server Proxy Web interface | zabbix | MySQL database password. |
| MYSQL_DATABASE | Server Proxy Web interface | zabbix for Zabbix server zabbix_proxy for Zabbix proxy | Zabbix database name. |
| POSTGRES_USER | Server Web interface | zabbix | PostgreSQL database user. |
| POSTGRES_PASSWORD | Server Web interface | zabbix | PostgreSQL database password. |

| Variable | Components | Default value | Description |
|------------------------|-------------------------|---|--|
| POSTGRES_DB | Server Web interface | zabbix for Zabbix server zabbix_proxy for Zabbix proxy | Zabbix database name. |
| PHP_TZ | Web-interface | Europe/Riga | Timezone in PHP format. Full list of supported timezones is available on php.net . |
| ZBX_SERVER_NAME | Web interface | Zabbix Docker | Visible Zabbix installation name in right top corner of the web interface. |
| ZBX_JAVAGATEWAY_ENABLE | Server Proxy | false | Enables communication with Zabbix Java gateway to collect Java related checks. |
| ZBX_ENABLE_SNMP_TRAPS | Server Proxy | false | Enables SNMP trap feature. It requires zabbix-smnptraps instance and shared volume <code>/var/lib/zabbix/snmptraps</code> to Zabbix server or Zabbix proxy. |

Volumes

The images allow to mount volumes using the following mount points:

| Volume | Description |
|--|---|
| Zabbix agent | |
| <code>/etc/zabbix/zabbix_agentd.conf</code> | The volume allows to include <code>*.conf</code> files and extend Zabbix agent using the <code>UserParameter</code> feature |
| <code>/var/lib/zabbix/modules</code> | The volume allows to load additional modules and extend Zabbix agent using the <code>LoadModule</code> feature |
| <code>/var/lib/zabbix/enc</code> | The volume is used to store TLS-related files. These file names are specified using <code>ZBX_TLSCAFILE</code> , <code>ZBX_TLSCRLFILE</code> , <code>ZBX_TLSKEY_FILE</code> and <code>ZBX_TLSPSKFILE</code> environment variables |
| Zabbix server | |
| <code>/usr/lib/zabbix/alertscripts</code> | The volume is used for custom alert scripts. It is the <code>AlertScriptsPath</code> parameter in <code>zabbix_server.conf</code> |
| <code>/usr/lib/zabbix/externalscripts</code> | The volume is used by external checks . It is the <code>ExternalScripts</code> parameter in <code>zabbix_server.conf</code> |
| <code>/var/lib/zabbix/modules</code> | The volume allows to load additional modules and extend Zabbix server using the <code>LoadModule</code> feature |
| <code>/var/lib/zabbix/enc</code> | The volume is used to store TLS related files. These file names are specified using <code>ZBX_TLSCAFILE</code> , <code>ZBX_TLSCRLFILE</code> , <code>ZBX_TLSKEY_FILE</code> and <code>ZBX_TLSPSKFILE</code> environment variables |
| <code>/var/lib/zabbix/ssl/certs</code> | The volume is used as location of SSL client certificate files for client authentication. It is the <code>SSLCertLocation</code> parameter in <code>zabbix_server.conf</code> |
| <code>/var/lib/zabbix/ssl/keys</code> | The volume is used as location of SSL private key files for client authentication. It is the <code>SSLKeyLocation</code> parameter in <code>zabbix_server.conf</code> |
| <code>/var/lib/zabbix/ssl/ssl_ca</code> | The volume is used as location of certificate authority (CA) files for SSL server certificate verification. It is the <code>SSLCALocation</code> parameter in <code>zabbix_server.conf</code> |
| <code>/var/lib/zabbix/snmptraps</code> | The volume is used as location of <code>snmptraps.log</code> file. It could be shared by <code>zabbix-smnptraps</code> container and inherited using the <code>volumes_from</code> Docker option while creating a new instance of Zabbix server. SNMP trap processing feature could be enabled by using shared volume and switching the <code>ZBX_ENABLE_SNMP_TRAPS</code> environment variable to 'true' |
| <code>/var/lib/zabbix/mibs</code> | The volume allows to add new MIB files. It does not support subdirectories, all MIBs must be placed in <code>/var/lib/zabbix/mibs</code> |
| Zabbix proxy | |
| <code>/usr/lib/zabbix/externalscripts</code> | The volume is used by external checks . It is the <code>ExternalScripts</code> parameter in <code>zabbix_proxy.conf</code> |
| <code>/var/lib/zabbix/db_data</code> | The volume allows to store database files on external devices. Supported only for Zabbix proxy with SQLite3 |
| <code>/var/lib/zabbix/modules</code> | The volume allows to load additional modules and extend Zabbix server using the <code>LoadModule</code> feature |

| Volume | Description |
|---|---|
| <code>/var/lib/zabbix/enc</code> | The volume is used to store TLS related files. These file names are specified using <code>ZBX_TLSCAFILE</code> , <code>ZBX_TLSCRLFILE</code> , <code>ZBX_TLSKEY_FILE</code> and <code>ZBX_TLSPSKFILE</code> environment variables |
| <code>/var/lib/zabbix/ssl/certs</code> | The volume is used as location of SSL client certificate files for client authentication. It is the <code>SSLCertLocation</code> parameter in <code>zabbix_proxy.conf</code> |
| <code>/var/lib/zabbix/ssl/keys</code> | The volume is used as location of SSL private key files for client authentication. It is the <code>SSLKeyLocation</code> parameter in <code>zabbix_proxy.conf</code> |
| <code>/var/lib/zabbix/ssl/ssl_ca</code> | The volume is used as location of certificate authority (CA) files for SSL server certificate verification. It is the <code>SSLCALocation</code> parameter in <code>zabbix_proxy.conf</code> |
| <code>/var/lib/zabbix/snmptraps</code> | The volume is used as location of <code>snmptraps.log</code> file. It could be shared by the <code>zabbix-snmptraps</code> container and inherited using the <code>volumes_from</code> Docker option while creating a new instance of Zabbix server. SNMP trap processing feature could be enabled by using shared volume and switching the <code>ZBX_ENABLE_SNMP_TRAPS</code> environment variable to 'true' |
| <code>/var/lib/zabbix/mibs</code> | The volume allows to add new MIB files. It does not support subdirectories, all MIBs must be placed in <code>/var/lib/zabbix/mibs</code> |
| Zabbix web interface based on Apache2 web server | |
| <code>/etc/ssl/apache2</code> | The volume allows to enable HTTPS for Zabbix web interface. The volume must contain the two <code>ssl.crt</code> and <code>ssl.key</code> files prepared for Apache2 SSL connections |
| Zabbix web interface based on Nginx web server | |
| <code>/etc/ssl/nginx</code> | The volume allows to enable HTTPS for Zabbix web interface. The volume must contain the two <code>ssl.crt</code> , <code>ssl.key</code> files and <code>dhparam.pem</code> prepared for Nginx SSL connections |
| Zabbix snmptraps | |
| <code>/var/lib/zabbix/snmptraps</code> | The volume contains the <code>snmptraps.log</code> log file named with received SNMP traps |
| <code>/var/lib/zabbix/mibs</code> | The volume allows to add new MIB files. It does not support subdirectories, all MIBs must be placed in <code>/var/lib/zabbix/mibs</code> |

For additional information, see Zabbix official repositories in Docker Hub.

Examples

Example 1

The example demonstrates how to run Zabbix server with MySQL database support, Zabbix web interface based on the Nginx web server and Zabbix Java gateway.

1. Create network dedicated for Zabbix component containers:

```
docker network create --subnet 172.20.0.0/16 --ip-range 172.20.240.0/20 zabbix-net
```

2. Start empty MySQL server instance

```
docker run --name mysql-server -t \
-e MYSQL_DATABASE="zabbix" \
```

```
-e MYSQL_USER="zabbix" \
-e MYSQL_PASSWORD="zabbix_pwd" \
-e MYSQL_ROOT_PASSWORD="root_pwd" \
--network=zabbix-net \
--restart unless-stopped \
-d mysql:8.0-oracle \
--character-set-server=utf8 --collation-server=utf8_bin \
--default-authentication-plugin=mysql_native_password
```

3. Start Zabbix Java gateway instance

```
docker run --name zabbix-java-gateway -t \
--network=zabbix-net \
--restart unless-stopped \
-d zabbix/zabbix-java-gateway:alpine-7.2-latest
```

4. Start Zabbix server instance and link the instance with created MySQL server instance

```
docker run --name zabbix-server-mysql -t \
-e DB_SERVER_HOST="mysql-server" \
-e MYSQL_DATABASE="zabbix" \
-e MYSQL_USER="zabbix" \
-e MYSQL_PASSWORD="zabbix_pwd" \
-e MYSQL_ROOT_PASSWORD="root_pwd" \
-e ZBX_JAVAGATEWAY="zabbix-java-gateway" \
--network=zabbix-net \
-p 10051:10051 \
--restart unless-stopped \
-d zabbix/zabbix-server-mysql:alpine-7.2-latest
```

5. Start Zabbix web interface and link the instance with created MySQL server and Zabbix server instances

```
docker run --name zabbix-web-nginx-mysql -t \
-e ZBX_SERVER_HOST="zabbix-server-mysql" \
-e DB_SERVER_HOST="mysql-server" \
-e MYSQL_DATABASE="zabbix" \
-e MYSQL_USER="zabbix" \
-e MYSQL_PASSWORD="zabbix_pwd" \
-e MYSQL_ROOT_PASSWORD="root_pwd" \
--network=zabbix-net \
-p 80:8080 \
--restart unless-stopped \
-d zabbix/zabbix-web-nginx-mysql:alpine-7.2-latest
```

Example 2

The example demonstrates how to run Zabbix server with PostgreSQL database support, Zabbix web interface based on the Nginx web server and SNMP trap feature.

1. Create network dedicated for Zabbix component containers:

```
docker network create --subnet 172.20.0.0/16 --ip-range 172.20.240.0/20 zabbix-net
```

2. Start empty PostgreSQL server instance

```
docker run --name postgres-server -t \
-e POSTGRES_USER="zabbix" \
-e POSTGRES_PASSWORD="zabbix_pwd" \
-e POSTGRES_DB="zabbix" \
--network=zabbix-net \
--restart unless-stopped \
-d postgres:latest
```

3. Start Zabbix snmptraps instance

```
docker run --name zabbix-snmptraps -t \
-v /zbx_instance/snmptraps:/var/lib/zabbix/snmptraps:rw \
-v /var/lib/zabbix/mibs:/usr/share/snmp/mibs:ro \
--network=zabbix-net \
-p 162:1162/udp \
```

```
--restart unless-stopped \
-d zabbix/zabbix-snmptests:alpine-7.2-latest
```

4. Start Zabbix server instance and link the instance with created PostgreSQL server instance

```
docker run --name zabbix-server-pgsql -t \
-e DB_SERVER_HOST="postgres-server" \
-e POSTGRES_USER="zabbix" \
-e POSTGRES_PASSWORD="zabbix_pwd" \
-e POSTGRES_DB="zabbix" \
-e ZBX_ENABLE_SNMP_TRAPS="true" \
--network=zabbix-net \
-p 10051:10051 \
--volumes-from zabbix-snmptests \
--restart unless-stopped \
-d zabbix/zabbix-server-pgsql:alpine-7.2-latest
```

5. Start Zabbix web interface and link the instance with created PostgreSQL server and Zabbix server instances

```
docker run --name zabbix-web-nginx-pgsql -t \
-e ZBX_SERVER_HOST="zabbix-server-pgsql" \
-e DB_SERVER_HOST="postgres-server" \
-e POSTGRES_USER="zabbix" \
-e POSTGRES_PASSWORD="zabbix_pwd" \
-e POSTGRES_DB="zabbix" \
--network=zabbix-net \
-p 443:8443 \
-p 80:8080 \
-v /etc/ssl/nginx:/etc/ssl/nginx:ro \
--restart unless-stopped \
-d zabbix/zabbix-web-nginx-pgsql:alpine-7.2-latest
```

Example 3

The example demonstrates how to run Zabbix server with MySQL database support, Zabbix web interface based on the Nginx web server and Zabbix Java gateway using podman on Red Hat 8.

1. Create new pod with name zabbix and exposed ports (web-interface, Zabbix server trapper):

```
podman pod create --name zabbix -p 80:8080 -p 10051:10051
```

2. (optional) Start Zabbix agent container in zabbix pod location:

```
podman run --name zabbix-agent \
-e ZBX_SERVER_HOST="127.0.0.1,localhost" \
--restart=always \
--pod=zabbix \
-d registry.connect.redhat.com/zabbix/zabbix-agent-70:latest
```

3. Create `./mysql/` directory on host and start Oracle MySQL server 8.0:

```
podman run --name mysql-server -t \
-e MYSQL_DATABASE="zabbix" \
-e MYSQL_USER="zabbix" \
-e MYSQL_PASSWORD="zabbix_pwd" \
-e MYSQL_ROOT_PASSWORD="root_pwd" \
-v ./mysql:/var/lib/mysql:Z \
--restart=always \
--pod=zabbix \
-d mysql:8.0 \
--character-set-server=utf8 --collation-server=utf8_bin \
--default-authentication-plugin=mysql_native_password
```

4. Start Zabbix server container:

```
podman run --name zabbix-server-mysql -t \
-e DB_SERVER_HOST="127.0.0.1" \
-e MYSQL_DATABASE="zabbix" \
-e MYSQL_USER="zabbix" \
-e MYSQL_PASSWORD="zabbix_pwd" \
```

```
-e MYSQL_ROOT_PASSWORD="root_pwd" \
-e ZBX_JAVAGATEWAY="127.0.0.1" \
--restart=always \
--pod=zabbix \
-d registry.connect.redhat.com/zabbix/zabbix-server-mysql-70
```

5. Start Zabbix Java Gateway container:

```
podman run --name zabbix-java-gateway -t \
--restart=always \
--pod=zabbix \
-d registry.connect.redhat.com/zabbix/zabbix-java-gateway-70
```

6. Start Zabbix web-interface container:

```
podman run --name zabbix-web-mysql -t \
-e ZBX_SERVER_HOST="127.0.0.1" \
-e DB_SERVER_HOST="127.0.0.1" \
-e MYSQL_DATABASE="zabbix" \
-e MYSQL_USER="zabbix" \
-e MYSQL_PASSWORD="zabbix_pwd" \
-e MYSQL_ROOT_PASSWORD="root_pwd" \
--restart=always \
--pod=zabbix \
-d registry.connect.redhat.com/zabbix/zabbix-web-mysql-70
```

Note:

Pod zabbix exposes 80/TCP port (HTTP) to host machine from 8080/TCP of zabbix-web-mysql container.

Docker Compose Alternatively, Zabbix can be installed using Docker Compose plugin. Compose files for defining and running multi-container Zabbix components are available in the official [Zabbix Docker repository](#) on GitHub.

Attention:

Official Zabbix compose files support version 3 of Docker Compose.

These compose files are added as examples; they are overloaded. For example, they contain proxies with both MySQL and SQLite3 support.

To obtain Docker compose files provided by Zabbix, clone the repository:

```
git clone https://github.com/zabbix/zabbix-docker.git
```

Switch to the required version:

```
git checkout 7.2
```

Compose configuration files and create and start containers:

```
docker compose -f ./docker-compose_v3_alpine_mysql_latest.yaml up
```

Replace docker-compose_v3_alpine_mysql_latest.yaml in the command above with the required configuration file.

The following options are available:

| File name | Description |
|--|---|
| docker-compose_v3_alpine_mysql_latest.yaml | The compose file starts the latest version of Zabbix 7.2 components on Alpine Linux with MySQL database support. |
| docker-compose_v3_alpine_mysql_latest_build.yaml | The compose file builds the latest version of Zabbix 7.2 and runs Zabbix components on Alpine Linux with MySQL database support. |
| docker-compose_v3_alpine_pgsql_latest.yaml | The compose file starts the latest version of Zabbix 7.2 components on Alpine Linux with PostgreSQL database support. |
| docker-compose_v3_alpine_pgsql_latest_build.yaml | The compose file builds the latest version of Zabbix 7.2 and runs Zabbix components on Alpine Linux with PostgreSQL database support. |
| docker-compose_v3_oracle_mysql_latest.yaml | The compose file starts the latest version of Zabbix 7.2 components on Oracle Linux with MySQL database support. |
| docker-compose_v3_oracle_mysql_latest_build.yaml | The compose file builds the latest version of Zabbix 7.2 and runs Zabbix components on Oracle Linux with MySQL database support. |

| File name | Description |
|--|---|
| <code>docker-compose_v3_ol_pgsql_base.yml</code> | The compose file runs the latest version of Zabbix 7.2 components on Oracle Linux with PostgreSQL database support. |
| <code>docker-compose_v3_ol_pgsql_local.yml</code> | The compose file locally builds the latest version of Zabbix 7.2 and runs Zabbix components on Oracle Linux with PostgreSQL database support. |
| <code>docker-compose_v3_ubuntu_mysql_latest.yml</code> | The compose file runs the latest version of Zabbix 7.2 components on Ubuntu 22.04 with MySQL database support. |
| <code>docker-compose_v3_ubuntu_mysql_local.yml</code> | The compose file locally builds the latest version of Zabbix 7.2 and runs Zabbix components on Ubuntu 22.04 with MySQL database support. |
| <code>docker-compose_v3_ubuntu_pgsql_latest.yml</code> | The compose file runs the latest version of Zabbix 7.2 components on Ubuntu 22.04 with PostgreSQL database support. |
| <code>docker-compose_v3_ubuntu_pgsql_local.yml</code> | The compose file locally builds the latest version of Zabbix 7.2 and runs Zabbix components on Ubuntu 22.04 with PostgreSQL database support. |

Storage

Compose files are configured to support local storage on a host machine. Docker Compose will create a `zbx_env` directory in the folder with the compose file when you run Zabbix components using the compose file. The directory will contain the same structure as described in the [Volumes](#) section and directory for database storage.

There are also volumes in read-only mode for `/etc/localtime` and `/etc/timezone` files.

Environment variables

The variable files have the following naming structure: `.env_<type of component>` and are located in the `env_vars` [directory](#). See [environment variables](#) for details about variable naming and available selection.

Examples

Example 1

```
git checkout 7.2
docker compose -f ./docker-compose_v3_alpine_mysql_latest.yml up -d
```

The command will download the latest Zabbix 7.2 images for each Zabbix component and run them in detach mode.

Attention:

Do not forget to download `.env_<type of component>` files from [github.com](https://github.com/zabbix/zabbix) official Zabbix repository with compose files.

Example 2

```
git checkout 7.2
docker compose -f ./docker-compose_v3_ubuntu_mysql_local.yml up -d
```

The command will download base image Ubuntu 22.04 (jammy), then build Zabbix 7.2 components locally and run them in detach mode.

6 Web interface installation

This section provides step-by-step instructions for installing Zabbix web interface. Zabbix frontend is written in PHP, so to run it a PHP supported webserver is needed.

Note:

You can find out more about setting up SSL for Zabbix frontend by referring to these [best practices](#).

Welcome screen

Open Zabbix frontend URL in the browser. If you have installed Zabbix from packages, the URL is:

- for Apache: `http://<server_ip_or_name>/zabbix`
- for Nginx: `http://<server_ip_or_name>`

You should see the first screen of the frontend installation wizard.

Use the *Default language* drop-down menu to change system default language and continue the installation process in the selected language (optional). For more information, see [Installation of additional frontend languages](#).

Note that setting the language to *English (en_US)* will also enable the US time/date format in the frontend.

| Pre-requisite | Minimum value | Description |
|----------------------------------|---------------|---|
| PHP version | 8.0.0 | |
| PHP option "memory_limit" | 128MB | In php.ini: memory_limit = 128M |
| PHP option "post_max_size" | 16MB | In php.ini: post_max_size = 16M |
| PHP option "upload_max_filesize" | 2MB | In php.ini: upload_max_filesize = 2M |
| PHP option "max_execution_time" | 300 seconds | In php.ini: max_execution_time = 300 (values 0 and -1 are also allowed) |
| PHP option "max_input_time" | 300 seconds | In php.ini: max_input_time = 300 (values 0 and -1 are also allowed) |

| Pre-requisite | Minimum value | Description |
|--|---------------------------|---|
| <i>PHP databases support</i> | One of: MySQL, PostgreSQL | See Requirements for the list of all mandatory and optional PHP extensions. Note that failed optional pre-requisites are displayed with a red <i>Warning</i> status, and the setup process can proceed even if they are not met. |
| <i>PHP bcmath</i> | must be enabled | In php.ini: mbstring.func_overload = 0 |
| <i>PHP mbstring</i> | must be enabled | |
| <i>PHP option "mbstring.func_overload"</i> | must be disabled | |
| <i>PHP option "session.auto_start"</i> | must be disabled | In php.ini: session.auto_start = 0 |
| <i>PHP option "arg_separator.output"</i> | & | In php.ini: arg_separator.output = "&" (value "&" is also allowed) |

Attention:

If the Apache user or user group needs to be changed, verify the permissions to the session folder; otherwise, Zabbix setup may be unable to continue.

Configure DB connection

Enter details for connecting to the database. Zabbix database must already be created.

If the *Database TLS encryption* option is checked, then additional fields for **configuring the TLS connection** to the database appear in the form (MySQL or PostgreSQL only).

If *Store credentials in* is set to HashiCorp Vault or CyberArk Vault, additional parameters will become available:

- for **HashiCorp Vault**: Vault API endpoint, vault prefix, secret path, and authentication token;
- for **CyberArk Vault**: Vault API endpoint, vault prefix, secret query string, and certificates. Upon marking *Vault certificates* checkbox, two new fields for specifying paths to SSL certificate file and SSL key file will appear.

BackNext step

Pre-installation summary

Review a summary of settings.

Note:

Providing the webserver user has write access to conf/ directory the configuration file would be saved automatically and it would be possible to proceed to the next step right away.

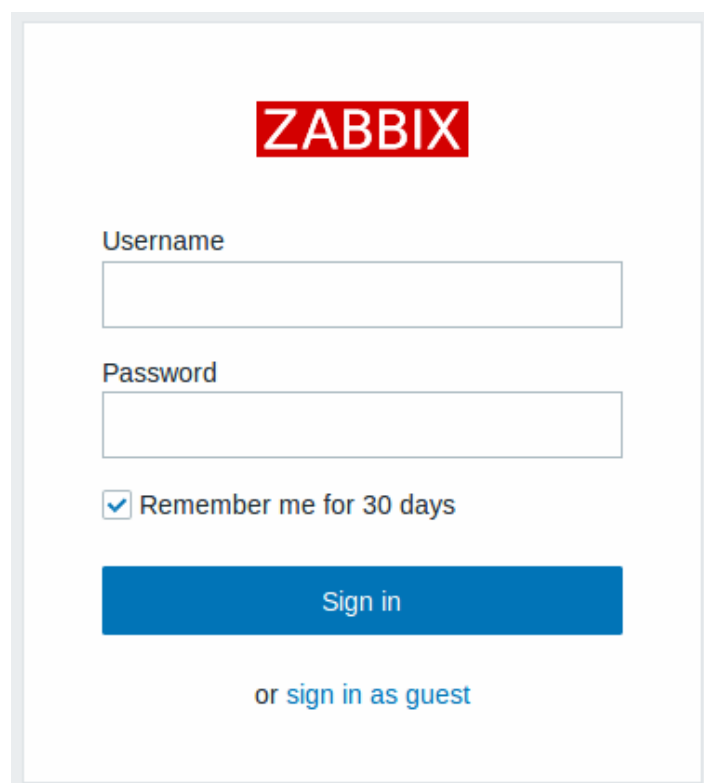

Finish the installation.

The screenshot shows the Zabbix installation completion screen. At the top left is the ZABBIX logo. To its right is the word "Install". Below the logo is a vertical list of installation steps: Welcome, Check of pre-requisites, Configure DB connection, Settings, Pre-installation summary, and Install. The "Install" step is highlighted. The main content area displays a green message: "Congratulations! You have successfully installed Zabbix frontend." Below this, it states: "Configuration file "/var/www/html/zabbix/conf/zabbix.conf.php" created." At the bottom right, there are two buttons: "Back" and "Finish".

Log in

Zabbix frontend is ready! The default user name is **Admin**, password **zabbix**.

The screenshot shows the Zabbix login form. At the top is the ZABBIX logo. Below it are two input fields: "Username" and "Password". Under the password field is a checkbox labeled "Remember me for 30 days". Below the checkbox is a blue "Sign in" button. At the bottom, there is a link that says "or sign in as guest".

Proceed to [getting started with Zabbix](#).

7 Upgrade procedure

Overview

This section provides upgrade information for Zabbix **7.2**:

- Using packages for [Red Hat Enterprise Linux](#) or [Debian/Ubuntu](#)
- Using [sources](#)

Related instructions:

- For servers in a high-availability (HA) cluster, see [Upgrading HA cluster](#)
- For TimescaleDB database, see [Upgrading TimescaleDB schema](#)

Upgrading Zabbix agents is recommended but not mandatory.

Upgrading Zabbix proxies is highly recommended. Zabbix server fully supports proxies that are of the same major version as the server. Zabbix server also supports proxies that are **no older** than Zabbix server previous LTS release version, but with limited functionality (data collection, execution of [remote commands](#), [immediate item value checks](#)). Configuration update is also disabled, and [outdated](#) proxies will only work with old configuration.

Attention:

Proxies that are older than Zabbix server previous LTS release version or newer than Zabbix server major version are not supported. Zabbix server will ignore data from unsupported proxies and all communication with Zabbix server will fail with a warning. For more information, see [Version compatibility](#).

To minimize downtime and data loss during the upgrade, it is recommended to stop, upgrade, and start Zabbix server and then stop, upgrade, and start Zabbix proxies one after another. During server downtime, running proxies will continue data collection. Once the server is up and running, [outdated](#) proxies will send the data to the newer server (proxy configuration will not be updated though) and will remain partly functional. Any notifications for problems during Zabbix server downtime will be generated only after the upgraded server is started.

If Zabbix proxy is started for the first time and the SQLite database file is missing, proxy creates it automatically.

Note that if Zabbix proxy uses SQLite3 and on startup detects that existing database file version is older than required, it will **delete the database file automatically** and create a new one. Therefore, history data stored in the SQLite database file will be lost. If Zabbix proxy's version is older than the database file version, Zabbix will log an error and exit.

Depending on the database size, the database upgrade to version 7.2 may take a long time.

Direct upgrade to Zabbix 7.2.x is possible from Zabbix **7.0.x**, **6.4.x**, **6.2.x**, **6.0.x**, **5.4.x**, **5.2.x**, **5.0.x**, **4.4.x**, **4.2.x**, **4.0.x**, **3.4.x**, **3.2.x**, **3.0.x**, **2.4.x**, **2.2.x** and **2.0.x**. For upgrading from earlier versions consult Zabbix documentation for 2.0 and earlier.

Note:

Please be aware that after upgrading some third-party software integrations in Zabbix might be affected, if the external software is not compatible with the upgraded Zabbix version.

The following upgrade notes are available:

| Upgrade from | Read full upgrade notes | Most important changes between versions |
|--------------|--|--|
| 7.0.x LTS | For: Zabbix 7.2 | Support of Oracle DB dropped. |
| 6.4.x | For: Zabbix 7.0 Zabbix 7.2 | Minimum required PHP version upped from 7.4.0 to 8.0.0. Asynchronous pollers for agent, HTTP agent and SNMP walk[oid] checks. Separate database table for proxies. Default location for Windows agent configuration file changed. Oracle DB deprecated. Old numeric (float) value type dropped. |
| 6.2.x | For: Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required MySQL version raised from 8.0.0 to 8.0.30. 'libevent_pthreads' library is required for Zabbix server/proxy. Upon the first launch after an upgrade, Zabbix proxy with SQLite3 automatically drops the old version of the database (with all the history) and creates a new one. |

| Upgrade from | Read full upgrade notes | Most important changes between versions |
|--------------|--|--|
| 6.0.x LTS | For: Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required PHP version upped from 7.2.5 to 7.4.0. Service monitoring reworked significantly. Deterministic triggers need to be created during the upgrade. If binary logging is enabled for MySQL/MariaDB, this requires superuser privileges or setting the variable/configuration parameter <code>log_bin_trust_function_creators = 1</code> . See Database creation scripts for instructions how to set the variable. |
| 5.4.x | For: Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required database versions upped. Server/proxy will not start if outdated database. Audit log records lost because of database structure change. |
| 5.2.x | For: Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required database versions upped. Aggregate items removed as a separate type. |
| 5.0.x LTS | For: Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required PHP version upped from 7.2.0 to 7.2.5. Password hashing algorithm changed from MD5 to bcrypt. |
| 4.4.x | For: Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Support of IBM DB2 dropped. Minimum required PHP version upped from 5.4.0 to 7.2.0. Minimum required database versions upped. Changed Zabbix PHP file directory. |
| 4.2.x | For: Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Jabber, Ez Texting media types removed. |
| 4.0.x LTS | For: Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Older proxies no longer can report data to an upgraded server. Newer agents no longer will be able to work with an older Zabbix server. |

| Upgrade from | Read full upgrade notes | Most important changes between versions |
|--------------|--|---|
| 3.4.x | For: Zabbix 4.0 Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | 'libpthread' and 'zlib' libraries now mandatory. Support for plain text protocol dropped and header is mandatory. Pre-1.4 version Zabbix agents are no longer supported. The Server parameter in passive proxy configuration now mandatory. |
| 3.2.x | For: Zabbix 3.4 Zabbix 4.0 Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | SQLite support as backend database dropped for Zabbix server/frontend. Perl Compatible Regular Expressions (PCRE) supported instead of POSIX extended. 'libpcre' and 'libevent' libraries mandatory for Zabbix server. Exit code checks added for user parameters, remote commands and system.run[] items without the 'nowait' flag as well as Zabbix server executed scripts. Zabbix Java gateway has to be upgraded to support new functionality. |
| 3.0.x LTS | For: Zabbix 3.2 Zabbix 3.4 Zabbix 4.0 Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Database upgrade may be slow, depending on the history table size. |
| 2.4.x | For: Zabbix 3.0 Zabbix 3.2 Zabbix 3.4 Zabbix 4.0 Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required PHP version upped from 5.3.0 to 5.4.0. LogFile agent parameter must be specified. |

| Upgrade from | Read full upgrade notes | Most important changes between versions |
|--------------|--|--|
| 2.2.x LTS | For: Zabbix 2.4 Zabbix 3.0 Zabbix 3.2 Zabbix 3.4 Zabbix 4.0 Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Node-based distributed monitoring removed. |
| 2.0.x | For: Zabbix 2.2 Zabbix 2.4 Zabbix 3.0 Zabbix 3.2 Zabbix 3.4 Zabbix 4.0 Zabbix 4.2 Zabbix 4.4 Zabbix 5.0 Zabbix 5.2 Zabbix 5.4 Zabbix 6.0 Zabbix 6.2 Zabbix 6.4 Zabbix 7.0 Zabbix 7.2 | Minimum required PHP version upped from 5.1.6 to 5.3.0. Case-sensitive MySQL database required for proper server work; character set utf8 and utf8_bin collation is required for Zabbix server to work properly with MySQL database. See database creation scripts . 'mysqli' PHP extension required instead of 'mysql'. |

1 Upgrade from sources

Overview

This section provides the steps required for a successful **upgrade** from Zabbix **7.0.x** to Zabbix **7.2.x** using official Zabbix sources.

Warning:

Before the upgrade make sure to read the relevant **upgrade notes**!

You may also want to check the **requirements** for 7.2.

Note:

It may be handy to run two parallel SSH sessions during the upgrade, executing the upgrade steps in one and monitoring the server/proxy logs in another. For example, run `tail -f zabbix_server.log` or `tail -f zabbix_proxy.log` in the second SSH session showing you the latest log file entries and possible errors in real time. This can be critical for production instances.

Server upgrade process

1 Stop server

Stop Zabbix server to make sure that no new data is inserted into database.

2 Back up the existing Zabbix database

This is a very important step. Make sure that you have a backup of your database. It will help if the upgrade procedure fails (lack of disk space, power off, any unexpected problem).

3 Back up configuration files, PHP files and Zabbix binaries

Make a backup copy of Zabbix binaries, configuration files and the PHP file directory.

4 Install new server binaries

Use these [instructions](#) to compile Zabbix server from sources.

5 Review server configuration parameters

Make sure to review [Upgrade notes](#) to check if any changes in the configuration parameters are required.

For new optional parameters, see the [What's new](#) page.

6 Start new Zabbix binaries

Start new binaries. Check log files to see if the binaries have started successfully.

Zabbix server will automatically upgrade the database. When starting up, Zabbix server reports the current (mandatory and optional) and required database versions. If the current mandatory version is older than the required version, Zabbix server automatically executes the required database upgrade patches. The start and progress level (percentage) of the database upgrade is written to the Zabbix server log file. When the upgrade is completed, a "database upgrade fully completed" message is written to the log file. If any of the upgrade patches fail, Zabbix server will not start. Zabbix server will also not start if the current mandatory database version is newer than the required one. Zabbix server will only start if the current mandatory database version corresponds to the required mandatory version.

```
8673:20161117:104750.259 current database version (mandatory/optional): 03040000/03040000
8673:20161117:104750.259 required mandatory version: 03040000
```

Before you start the server:

- Make sure the database user has enough permissions (create table, drop table, create index, drop index)
- Make sure you have enough free disk space.

7 Install new Zabbix web interface

The minimum required PHP version is 8.0.0. Update if needed and follow [installation instructions](#).

8 Clear web browser cookies and cache

After the upgrade you may need to clear web browser cookies and web browser cache for the Zabbix web interface to work properly.

Proxy upgrade process

1 Stop proxy

Stop Zabbix proxy.

2 Back up configuration files and Zabbix proxy binaries

Make a backup copy of the Zabbix proxy binary and configuration file.

3 Install new proxy binaries

Use these [instructions](#) to compile Zabbix proxy from sources.

4 Review proxy configuration parameters

There are no mandatory changes in this version to proxy [parameters](#).

5 Start new Zabbix proxy

Start the new Zabbix proxy. Check log files to see if the proxy has started successfully.

Zabbix proxy will automatically upgrade the database. Database upgrade takes place similarly as when starting [Zabbix server](#).

Agent upgrade process

Attention:

Upgrading agents is not mandatory. You only need to upgrade agents if it is required to access the new functionality.

The upgrade procedure described in this section may be used for upgrading both the Zabbix agent and the Zabbix agent 2.

1 Stop agent

Stop Zabbix agent.

2 Back up configuration files and Zabbix agent binaries

Make a backup copy of the Zabbix agent binary and configuration file.

3 Install new agent binaries

Use these [instructions](#) to compile Zabbix agent from sources.

Alternatively, you may download pre-compiled Zabbix agents from the [Zabbix download page](#).

4 Review agent configuration parameters

There are no mandatory changes in this version neither to [agent](#) nor to [agent 2](#) parameters.

5 Start new Zabbix agent

Start the new Zabbix agent. Check log files to see if the agent has started successfully.

Upgrade between minor versions

When upgrading between minor versions of 7.2.x (for example from 7.2.1 to 7.2.3) it is required to execute the same actions for server/proxy/agent as during the upgrade between major versions. The only difference is that when upgrading between minor versions no changes to the database are made.

2 Upgrade from packages

Overview

This section provides the steps required for a successful [upgrade](#) using official RPM and DEB packages provided by Zabbix for:

- [Red Hat Enterprise Linux](#)
- [Debian/Ubuntu](#)

Zabbix packages from OS repositories

Often, OS distributions (in particular, Debian-based distributions) provide their own Zabbix packages.

Note that these packages are not supported by Zabbix, they are typically out of date and lack the latest features and bug fixes. Only the packages from [repo.zabbix.com](#) are officially supported.

If you are upgrading from packages provided by OS distributions (or had them installed at some point), follow this procedure to switch to official Zabbix packages:

1. Always uninstall the old packages first.
2. Check for residual files that may have been left after deinstallation.
3. Install official packages following [installation instructions](#) provided by Zabbix.

Never do a direct update, as this may result in a broken installation.

1 Red Hat Enterprise Linux

Overview

This section provides instructions on upgrading from Zabbix **7.0.x** to the latest version of Zabbix **7.2.x** using official Zabbix packages for Red Hat Enterprise Linux or its derivatives - AlmaLinux, CentOS Stream, Oracle Linux, and Rocky Linux.

Warning:

Before upgrading, please review the relevant [upgrade notes](#) and ensure that your system meets the [requirements](#) for Zabbix 7.2.

Note:

Consider running two parallel SSH sessions during the upgrade: one for executing the upgrade steps and another for monitoring server/proxy logs. For example, run `tail -f zabbix_server.log` or `tail -f zabbix_proxy.log` in the second session to view the latest log entries and possible errors in real time. This can be critical for production instances.

For instructions on upgrading between Zabbix 7.2.x minor versions (for example, from 7.2.1 to 7.2.3), see [Upgrade between minor versions](#).

Upgrade procedure

1 Stop Zabbix processes

Stop Zabbix server to make sure that no new data is inserted into database:

```
systemctl stop zabbix-server
```

If upgrading Zabbix proxy, agent, or agent 2, stop these components too:

```
systemctl stop zabbix-proxy
systemctl stop zabbix-agent
systemctl stop zabbix-agent2
```

2 Back up Zabbix database

Back up your existing Zabbix database to safeguard against upgrade failures (for example, disk space issues, power loss, or unexpected problems).

3 Back up Zabbix configuration files, PHP files, and Zabbix binaries

Back up existing Zabbix configuration files, PHP files, and Zabbix binaries.

For configuration files, run:

```
mkdir /opt/zabbix-backup/
cp /etc/zabbix/zabbix_server.conf /opt/zabbix-backup/
cp /etc/httpd/conf.d/zabbix.conf /opt/zabbix-backup/
```

For PHP files and Zabbix binaries, run:

```
cp -R /usr/share/zabbix/ /opt/zabbix-backup/
cp -R /usr/share/zabbix-* /opt/zabbix-backup/
```

4 Update repository configuration package

Before proceeding with the upgrade, update your current repository package to the latest version to ensure compatibility with the newest packages and to include any recent security patches or bug fixes.

On **RHEL 9**, run:

```
rpm -Uvh https://repo.zabbix.com/zabbix/7.2/release/rhel/9/noarch/zabbix-release-latest.el9.noarch.rpm
```

On **RHEL 8**, run:

```
rpm -Uvh https://repo.zabbix.com/zabbix/7.2/release/rhel/8/noarch/zabbix-release-latest.el8.noarch.rpm
```

Note:

For older RHEL versions or its derivatives, replace the link above with the correct one from the [Zabbix repository](#). Note, however, that packages for these versions may not include all Zabbix components, and to upgrade those components from packages, consider upgrading your OS. For a list of components included, see [Zabbix packages](#).

Then, clean up the dnf package manager's cache (including headers, metadata, and package files downloaded during previous installations or updates):

```
dnf clean all
```

On the next dnf operation, dnf will download fresh metadata from the repositories since the old metadata is cleared.

See also: [Known issues](#) for updating the repository configuration package on RHEL.

5 Upgrade Zabbix components

To upgrade Zabbix components, run:

```
dnf install zabbix-server-mysql zabbix-web-mysql zabbix-agent
```

- If using PostgreSQL, replace mysql with postgresql in the command.
- If upgrading the proxy, replace server with proxy in the command.
- If upgrading the agent 2, replace zabbix-agent with zabbix-agent2 zabbix-agent2-plugin-* in the command.

Attention:

Upgrading Zabbix agent 2 with the `dnf install zabbix-agent2` command could lead to an error. For more information, see [Known issues](#).

Then, to upgrade Zabbix frontend with Apache and restart Apache, run:

```
dnf install zabbix-apache-conf
systemctl restart httpd
```

6 Review component configuration parameters

Review the relevant [upgrade notes](#) to check if any changes in the configuration parameters are necessary.

For new optional parameters, see the [What's new](#) page.

7 Start Zabbix processes

Start the upgraded Zabbix components:

```
systemctl start zabbix-server
systemctl start zabbix-proxy
systemctl start zabbix-agent
systemctl start zabbix-agent2
```

8 Clear web browser cookies and cache

After the upgrade, you may need to clear web browser cookies and web browser cache for the Zabbix web interface to work properly.

Upgrade between minor versions

It is possible to upgrade between Zabbix 7.2.x minor versions (for example, from 7.2.1 to 7.2.3).

To upgrade all Zabbix components, run:

```
dnf upgrade 'zabbix-*
```

- To upgrade Zabbix server only, replace 'zabbix-*' with 'zabbix-server-*' in the command.
- To upgrade Zabbix proxy only, replace 'zabbix-*' with 'zabbix-proxy-*' in the command.
- To upgrade Zabbix agent only, replace 'zabbix-*' with 'zabbix-agent-*' in the command.
- To upgrade Zabbix agent 2 only, replace 'zabbix-*' with 'zabbix-agent2-*' in the command.

2 Debian/Ubuntu

Overview

This section provides instructions on upgrading from Zabbix **7.0.x** to the latest version of Zabbix **7.2.x** using official Zabbix packages for Debian/Ubuntu.

Warning:

Before upgrading, please review the relevant [upgrade notes](#) and ensure that your system meets the [requirements](#) for Zabbix 7.2.

Note:

Consider running two parallel SSH sessions during the upgrade: one for executing the upgrade steps and another for monitoring server/proxy logs. For example, run `tail -f zabbix_server.log` or `tail -f zabbix_proxy.log` in the second session to view the latest log entries and possible errors in real time. This can be critical for production instances.

For instructions on upgrading between Zabbix 7.2.x minor versions (for example, from 7.2.1 to 7.2.3), see [Upgrade between minor versions](#).

Upgrade procedure

1 Stop Zabbix processes

Stop Zabbix server to make sure that no new data is inserted into database:

```
systemctl stop zabbix-server
```

If upgrading Zabbix proxy, agent, or agent 2, stop these components too:

```
systemctl stop zabbix-proxy
systemctl stop zabbix-agent
systemctl stop zabbix-agent2
```

2 Back up Zabbix database

Back up your existing Zabbix database to safeguard against upgrade failures (for example, disk space issues, power loss, or unexpected problems).

3 Back up Zabbix configuration files, PHP files, and Zabbix binaries

Back up existing Zabbix configuration files, PHP files, and Zabbix binaries.

For configuration files, run:

```
mkdir /opt/zabbix-backup/  
cp /etc/zabbix/zabbix_server.conf /opt/zabbix-backup/  
cp /etc/apache2/conf-enabled/zabbix.conf /opt/zabbix-backup/
```

For PHP files and Zabbix binaries, run:

```
cp -R /usr/share/zabbix/ /opt/zabbix-backup/  
cp -R /usr/share/zabbix-* /opt/zabbix-backup/
```

4 Update repository configuration package

Before proceeding with the upgrade, uninstall your current Zabbix repository package:

```
rm -Rf /etc/apt/sources.list.d/zabbix.list
```

You may also need to manually remove any old Zabbix packages from your working directory (e.g., `rm zabbix-release_latest+debian12`) before downloading the new one to prevent the package manager from reusing an outdated version during the upgrade process.

Then, install the latest repository configuration package to ensure compatibility with the newest packages and to include any recent security patches or bug fixes.

On **Debian 12**, run:

```
wget https://repo.zabbix.com/zabbix/7.2/release/debian/pool/main/z/zabbix-release/zabbix-release_latest+debian12_all.deb  
dpkg -i zabbix-release_latest+debian12_all.deb
```

Note:

For older Debian versions, replace the link above with the correct one from the [Zabbix repository](#). Note, however, that packages for these versions may not include all Zabbix components, and to upgrade those components from packages, consider upgrading your OS. For a list of components included, see [Zabbix packages](#).

On **Ubuntu 24.04**, run:

```
wget https://repo.zabbix.com/zabbix/7.2/release/ubuntu/pool/main/z/zabbix-release/zabbix-release_latest+ubuntu24.04_all.deb  
dpkg -i zabbix-release_latest+ubuntu24.04_all.deb
```

On **Ubuntu 22.04**, run:

```
wget https://repo.zabbix.com/zabbix/7.2/release/ubuntu/pool/main/z/zabbix-release/zabbix-release_latest+ubuntu22.04_all.deb  
dpkg -i zabbix-release_latest+ubuntu22.04_all.deb
```

Note:

For older Ubuntu versions, replace the link above with the correct one from the [Zabbix repository](#). Note, however, that packages for these versions may not include all Zabbix components, and to upgrade those components from packages, consider upgrading your OS. For a list of components included, see [Zabbix packages](#).

You may see a prompt about the Zabbix repository configuration:

```
Configuration file '/etc/apt/sources.list.d/zabbix.list'  
==> Deleted (by you or by a script) since installation.  
==> Package distributor has shipped an updated version.  
What would you like to do about it ? Your options are:  
Y or I : install the package maintainer's version  
N or O : keep your currently-installed version  
D       : show the differences between the versions  
Z       : start a shell to examine the situation  
The default action is to keep your current version.  
*** zabbix.list (Y/I/N/O/D/Z) [default=N] ?
```

Enter Y (or I) to install the package maintainer's version of the Zabbix repository configuration.

Then, update the repository information:

```
apt update
```

5 Upgrade Zabbix components

To upgrade Zabbix components, run:

```
apt install --only-upgrade zabbix-server-mysql zabbix-frontend-php zabbix-agent
```

- If using PostgreSQL, replace `mysql` with `pgsql` in the command.
- If upgrading proxy, replace `server` with `proxy` in the command.
- If upgrading Zabbix agent 2, replace `zabbix-agent` with `zabbix-agent2 zabbix-agent2-plugin-*` in the command.

Attention:

Upgrading Zabbix agent 2 with the `apt install zabbix-agent2` command could lead to an error. For more information, see [Known issues](#).

You may see a prompt about the Zabbix server (or proxy) configuration:

```
Configuration file '/etc/zabbix/zabbix_server.conf'
==> Modified (by you or by a script) since installation.
==> Package distributor has shipped an updated version.
What would you like to do about it ? Your options are:
Y or I  : install the package maintainer's version
N or O  : keep your currently-installed version
D       : show the differences between the versions
Z       : start a shell to examine the situation
The default action is to keep your current version.
*** zabbix_server.conf (Y/I/N/O/D/Z) [default=N] ?
```

Enter the option that best fits your situation. For example, enter D to compare the current and new configuration, then decide if you want to install the package maintainer's version (Y or I).

Then, to upgrade Zabbix frontend with Apache and restart Apache, run:

```
apt install zabbix-apache-conf
systemctl restart apache2
```

6 Review component configuration parameters

Review the relevant [upgrade notes](#) to check if any changes in the configuration parameters are necessary.

For new optional parameters, see the [What's new](#) page.

7 Start Zabbix processes

Start the upgraded Zabbix components:

```
systemctl start zabbix-server
systemctl start zabbix-proxy
systemctl start zabbix-agent
systemctl start zabbix-agent2
```

8 Clear web browser cookies and cache

After the upgrade, you may need to clear web browser cookies and web browser cache for the Zabbix web interface to work properly.

Upgrade between minor versions

It is possible to upgrade between Zabbix 7.2.x minor versions (for example, from 7.2.1 to 7.2.3).

First, update the repository information:

```
apt update
```

Then, to upgrade all Zabbix components, run:

```
apt install --only-upgrade 'zabbix*'
```

- To upgrade Zabbix server only, replace `'zabbix*'` with `'zabbix-server*'` in the command.

- To upgrade Zabbix proxy only, replace 'zabbix*' with 'zabbix-proxy*' in the command.
- To upgrade Zabbix agent only, replace 'zabbix*' with 'zabbix-agent*' in the command.
- To upgrade Zabbix agent 2 only, replace 'zabbix*' with 'zabbix-agent2*' in the command.

3 Upgrade from containers

Overview

This section describes steps required for a successful **upgrade** to Zabbix **7.2.x** containers.

Separate sets of instructions are available for upgrading individual Zabbix component **images** and Docker **compose files**.

Warning:

Before the upgrade make sure to read the relevant **upgrade notes**!

Attention:

Before starting the upgrade, verify that users have the necessary permissions to the database for upgrading purposes.

For upgrades from Zabbix 6.0 or older, deterministic triggers will need to be created during the upgrade. If binary logging is enabled for MySQL/MariaDB, this requires superuser privileges or setting the variable/configuration parameter `log_bin_trust_function_creators = 1`. See **Database creation scripts** for instructions how to set the variable.

Note that if executing from a console, the variable will only be set temporarily and will be dropped when a Docker is restarted. In this case, keep your SQL service running, only stop zabbix-server service by running 'docker compose down zabbix-server' and then 'docker compose up -d zabbix-server'.

Alternatively, you can set this variable in the configuration file.

Depending on the size of a database upgrade to version 7.2 may take quite a long time.

Zabbix image upgrade

The steps listed below can be used to upgrade any Zabbix component. Replace `zabbix-server-mysql` with the required component image name.

1. Check current image version:

```
docker inspect -f '{{ .Config.Image }}' zabbix-server-mysql
```

2. Pull desired image version, for example:

```
docker pull zabbix/zabbix-server-mysql:alpine-7.2-latest
```

`zabbix/zabbix-server-mysql:alpine-7.2-latest` will pull the latest released minor version of Zabbix server 7.2 with MySQL support based on Alpine Linux. Replace it with the name of the Docker repository and tags combination you need. See **Installation from containers** for a list of available options.

3. Stop the container:

```
docker stop zabbix-server-mysql
```

4. Remove the container:

```
docker rm zabbix-server-mysql
```

5. Launch the updated container by executing `docker run` command followed by additional arguments to specify required **environment variables** and/or **mount points**.

Configuration examples

Zabbix server with MySQL:

```
docker run --name zabbix-server-mysql -t \
  -e DB_SERVER_HOST="mysql-server" \
  -e MYSQL_DATABASE="zabbix" \
  -e MYSQL_USER="zabbix" \
  -e MYSQL_PASSWORD="zabbix_pwd" \
  -e MYSQL_ROOT_PASSWORD="root_pwd" \
  -e ZBX_JAVAGATEWAY="zabbix-java-gateway" \
  --network=zabbix-net \
  -p 10051:10051 \
  --restart unless-stopped \
```

```
-d zabbix/zabbix-server-mysql:alpine-7.2-latest
```

Zabbix server with PostgreSQL:

```
docker run --name zabbix-server-pgsql -t \
-e DB_SERVER_HOST="postgres-server" \
-e POSTGRES_USER="zabbix" \
-e POSTGRES_PASSWORD="zabbix_pwd" \
-e POSTGRES_DB="zabbix" \
-e ZBX_ENABLE_SNMP_TRAPS="true" \
--network=zabbix-net \
-p 10051:10051 \
--volumes-from zabbix-snmptools \
--restart unless-stopped \
-d zabbix/zabbix-server-pgsql:alpine-7.2-latest
```

More configuration examples, including examples for other Zabbix components, are available on the [Installation from containers](#) page.

6. Verify the update:

```
docker logs -f zabbix-server-mysql
```

Compose files

Follow upgrade instructions in this section, if you installed Zabbix using [compose file](#).

1. Check current image version:

```
docker inspect -f '{{.Config.Image}}' zabbix-server-mysql
```

2. Pull the latest updates from the GitHub [repository](#) and switch to the required branch:

```
git pull
git checkout 7.2
```

3. Start Zabbix components using new compose file:

```
docker-compose -f ./docker-compose_v3_alpine_mysql_latest.yaml up -d
```

4. Verify the update:

```
docker logs -f zabbix-server-mysql
```

See [Installation from containers](#) for more details, including lists of supported environment variables and volume mount points.

8 Known issues

See also: [Compilation issues](#).

Proxy startup with MySQL 8.0.0-8.0.17

zabbix_proxy on MySQL versions 8.0.0-8.0.17 fails with the following "access denied" error:

```
[Z3001] connection to database 'zabbix' failed: [1227] Access denied; you need (at least one of) the SUPER
```

That is due to MySQL 8.0.0 starting to enforce special permissions for setting session variables. However, in 8.0.18 this behavior was removed: [As of MySQL 8.0.18, setting the session value of this system variable is no longer a restricted operation](#).

The workaround is based on granting additional privileges to the zabbix user:

For MySQL versions 8.0.14 - 8.0.17:

```
grant SESSION_VARIABLES_ADMIN on *.* to 'zabbix'@'localhost';
```

For MySQL versions 8.0.0 - 8.0.13:

```
grant SYSTEM_VARIABLES_ADMIN on *.* to 'zabbix'@'localhost';
```

Upgrade

SQL mode setting for successful upgrade

The `sql_mode` setting in MySQL/MariaDB must have the "STRICT_TRANS_TABLES" mode set. If it is absent, the Zabbix database upgrade will fail (see also [ZBX-19435](#)).

Upgrade with MariaDB 10.2.1 and before

Upgrading Zabbix may fail if database tables were created with MariaDB 10.2.1 and before, because in those versions the default row format is compact. This can be fixed by changing the row format to dynamic (see also [ZBX-17690](#)).

Templates

Template compatibility in dual-stack (IPv4/IPv6) environments

In dual-stack environments (systems configured to support both IPv4 and IPv6), the hostname `localhost` typically resolves to both IPv4 and IPv6 addresses. Due to the common prioritization of IPv6 over IPv4 by many operating systems and DNS resolvers, Zabbix templates may fail to work correctly if the service being monitored is configured to listen only on IPv4.

Services that are not configured to listen on IPv6 addresses may become inaccessible, leading to monitoring failures. Users might configure access correctly for IPv4 but still face connectivity issues due to the default behavior of prioritizing IPv6.

A workaround for this is to ensure that the services (Nginx, Apache, PostgreSQL, etc.) are configured to listen on both IPv4 and IPv6 addresses, and Zabbix server/agent is allowed access via IPv6. Additionally, in Zabbix templates and configurations, use `localhost` explicitly instead of `127.0.0.1` to ensure compatibility with both IPv4 and IPv6.

For example, when monitoring PostgreSQL with the [PostgreSQL by Zabbix agent 2](#) template, you may need to edit the `pg_hba.conf` file to allow connections for the `zbx_monitor` user. If the dual-stack environment prioritizes IPv6 (system resolves `localhost` to `::1`) and you configure `localhost` but only add an IPv4 entry (`127.0.0.1/32`), the connection will fail because there is no matching IPv6 entry.

The following `pg_hba.conf` file example ensures that the `zbx_monitor` user can connect to any database from the local machine using both IPv4 and IPv6 addresses with different authentication methods:

| # | TYPE | DATABASE | USER | ADDRESS | METHOD |
|---|------|----------|-------------|--------------|---------------|
| | host | all | zbx_monitor | localhost | trust |
| | host | all | zbx_monitor | 127.0.0.1/32 | md5 |
| | host | all | zbx_monitor | ::1/128 | scram-sha-256 |

If necessary, you can also use the IPv4 address (`127.0.0.1`) directly when configuring the [PostgreSQL by Zabbix agent 2](#) template macro for the connection string.

Accidental installation of EPEL Zabbix packages

With EPEL repository installed and enabled, installing Zabbix from packages will lead to EPEL Zabbix packages being installed rather than official Zabbix packages.

In this case uninstall Zabbix packages from EPEL, i.e.:

```
dnf remove zabbix-server-mysql
```

Block Zabbix packages from EPEL. Add the following line in the `/etc/yum.conf` file:

```
exclude=zabbix7.0*
```

Install Zabbix server again:

```
dnf install zabbix-server-mysql
```

Notice that official Zabbix packages have the word `release` in their version string:

```
7.0.0-release1.el8
```

Zabbix packages for RHEL on Red Hat UBI environments

When installing Zabbix from Red Hat Enterprise Linux packages on [Red Hat Universal Base Image](#) environments, ensure access to required repositories and dependencies. Zabbix packages depend on `libOpenIPMI.so` and `libOpenIPMIposix.so` libraries, which are not provided by any package in the default package manager repositories enabled on UBI systems and will result in installation failures.

The `libOpenIPMI.so` and `libOpenIPMIposix.so` libraries are available in the `OpenIPMI-libs` package, which is provided by the `redhat-#-for-<arch>-appstream-rpms` repository. Access to this repository is curated by subscriptions, which, in the case of UBI environments, get propagated by mounting repository configuration and secrets directories of the RHEL host into the container file-system namespace.

For more information, see [ZBX-24291](#).

Expired signing key for RHEL packages

When upgrading Zabbix on [Red Hat Enterprise Linux](#) or its derivatives, you may encounter an expired signing key issue for packages on [Zabbix repository](#). When a signing key expires, attempts to verify package signatures will result in an error indicating that the certificate or key is no longer valid. For example:

```
error: Verifying a signature using certificate D9AA84C2B617479C6E4FCF4D19F2475308EFA7DD (Zabbix LLC (Jul 2
  1. Certificate 19F2475308EFA7DD invalid: certificate is not alive
    because: The primary key is not live
    because: Expired on 2024-07-04T11:41:23Z
  2. Key 19F2475308EFA7DD invalid: key is not alive
    because: The primary key is not live
    because: Expired on 2024-07-04T11:41:23Z
```

To resolve such issues, manually reinstall the latest zabbix-release package for your specific variant of RHEL (replace the link below with the correct one from [Zabbix repository](#)).

For example, on **RHEL 9**, run:

```
rpm -Uvh https://repo.zabbix.com/zabbix/7.2/release/rhel/9/noarch/zabbix-release-latest.el9.noarch.rpm
```

Then, update the repository information:

```
dnf update
```

For more information, see [ZBX-24761](#).

Timescale DB: high memory usage with large number of partitions

PostgreSQL versions 9.6-12 use too much memory when updating tables with a large number of partitions. This issue manifests itself when Zabbix updates trends on systems with TimescaleDB if trends are split into relatively small (e.g. 1 day) chunks. This leads to hundreds of chunks present in the trends tables with default housekeeping settings - the condition where PostgreSQL is likely to run out of memory.

The issue has been resolved since Zabbix 5.0.1 for new installations with TimescaleDB, but if TimescaleDB was set up with Zabbix before that, please see [ZBX-16347](#) for the migration notes.

Timescale DB 2.5.0: compression policy can fail on tables that contain integers

This issue manifests when TimescaleDB 2.5.0/2.5.1 is used. It has been resolved since TimescaleDB 2.5.2.

For more information, please see [TimescaleDB Issue #3773](#).

Database TLS connection with MariaDB

Database TLS connection is not supported with the 'verify_ca' option for the DBTLSConnect [parameter](#) if MariaDB is used.

Possible deadlocks with MySQL/MariaDB

When running under high load, and with more than one LLD worker involved, it is possible to run into a deadlock caused by an InnoDB error related to the row-locking strategy (see [upstream bug](#)). The error has been fixed in MySQL since 8.0.29, but not in MariaDB. For more details, see [ZBX-21506](#).

Global event correlation

Events may not get correlated correctly if the time interval between the first and second event is very small, i.e. half a second and less.

Numeric (float) data type range with PostgreSQL 11 and earlier

PostgreSQL 11 and earlier versions only support floating point value range of approximately -1.34E-154 to 1.34E+154.

NetBSD 8.0 and newer

Various Zabbix processes may randomly crash on startup on the NetBSD versions 8.X and 9.X. That is due to the too small default stack size (4MB), which must be increased by running:

```
ulimit -s 10240
```

For more information, please see the related problem report: [ZBX-18275](#).

Regular expression limitations in Zabbix agent 2

Zabbix agent 2 does not support lookaheads and lookbehinds in regular expressions due to the standard Go regexp library limitations.

IPMI checks

IPMI checks will not work with the standard OpenIPMI library package on Debian prior to 9 (stretch) and Ubuntu prior to 16.04 (xenial). To fix that, recompile OpenIPMI library with OpenSSL enabled as discussed in [ZBX-6139](#).

SSH checks

- Some Linux distributions like Debian, Ubuntu do not support encrypted private keys (with passphrase) if the libssh2 library is installed from packages. Please see [ZBX-4850](#) for more details.
- When using libssh 0.9.x on some Linux distributions with OpenSSH 8, SSH checks may occasionally report "Cannot read data from SSH server". This is caused by a libssh [issue](#) ([more detailed report](#)). The error is expected to have been fixed by a stable libssh 0.9.5 release. See also [ZBX-17756](#) for details.
- Using the pipe "|" in the SSH script may lead to a "Cannot read data from SSH server" error. In this case it is recommended to upgrade the libssh library version. See also [ZBX-21337](#) for details.

ODBC checks

- MySQL unixODBC driver should not be used with Zabbix server or Zabbix proxy compiled against MariaDB connector library and vice versa, if possible it is also better to avoid using the same connector as the driver due to an [upstream bug](#). Suggested setup:

PostgreSQL, SQLite or Oracle connector → MariaDB or MySQL unixODBC driver MariaDB connector → MariaDB unixODBC driver MySQL connector → MySQL unixODBC driver

See [ZBX-7665](#) for more information and available workarounds.

- XML data queried from Microsoft SQL Server may get truncated in various ways on Linux and UNIX systems.
- It has been observed that using ODBC checks for monitoring Oracle databases using various versions of Oracle Instant Client for Linux causes Zabbix server to crash. See also: [ZBX-18402](#), [ZBX-20803](#).
- If using FreeTDS UnixODBC driver, you need to prepend a 'SET NOCOUNT ON' statement to an SQL query (for example, SET NOCOUNT ON DECLARE @strsql NVARCHAR(max) SET @strsql = ...). Otherwise, database monitor item in Zabbix will fail to retrieve the information with an error "SQL query returned empty result". See [ZBX-19917](#) for more information.

Incorrect request method parameter in items

The request method parameter, used only in HTTP checks, may be incorrectly set to '1', a non-default value for all items as a result of upgrade from a pre-4.0 Zabbix version. For details on how to fix this situation, see [ZBX-19308](#).

Web monitoring and HTTP agent

Zabbix server leaks memory on some Linux distributions due to an [upstream bug](#) when "SSL verify peer" is enabled in web scenarios or HTTP agent. Please see [ZBX-10486](#) for more information and available workarounds.

Simple checks

There is a bug in **fping** versions earlier than v3.10 that mishandles duplicate echo replay packets. This may cause unexpected results for icmping, icmpingloss, icmpingsec items. It is recommended to use the latest version of **fping**. Please see [ZBX-11726](#) for more details.

Errors with fping execution in rootless containers

When containers are running in rootless mode or in a specific-restrictions environment, you may face errors related to fping execution when performing ICMP checks, such as fping: Operation not permitted or all packets to all resources lost.

To fix this problem add --cap-add=net_raw to "docker run" or "podman run" commands.

Additionally fping execution in non-root environments may require sysctl modification, i.e.:

```
sudo sysctl -w "net.ipv4.ping_group_range=0 1995"
```

where "1995" is the zabbix GID. For more details, see [ZBX-22833](#).

SNMP checks

If the OpenBSD operating system is used, a use-after-free bug in the Net-SNMP library up to the 5.7.3 version can cause a crash of Zabbix server if the SourceIP parameter is set in the Zabbix server configuration file. As a workaround, please do not set the SourceIP parameter. The same problem applies also for Linux, but it does not cause Zabbix server to stop working. A local patch for the net-snmp package on OpenBSD was applied and will be released with OpenBSD 6.3.

SNMP data spikes

Spikes in SNMP data have been observed that may be related to certain physical factors like voltage spikes in the mains. See [ZBX-14318](#) more details.

SNMP traps

The "net-snmp-perl" package, needed for SNMP traps, has been removed in RHEL 8.0-8.2; re-added in RHEL 8.3.

So if you are using RHEL 8.0-8.2, the best solution is to upgrade to RHEL 8.3.

Please also see [ZBX-17192](#) for more information.

Alerter process crash in RHEL 7

Instances of a Zabbix server alerter process crash have been encountered in RHEL 7. Please see [ZBX-10461](#) for details.

Upgrading Zabbix agent 2 (6.0.5 or older)

When upgrading Zabbix agent 2 (version 6.0.5 or older) from packages, a plugin-related file conflict error may occur. To fix the error, back up your agent 2 configuration (if necessary), uninstall agent 2 and install it anew.

On RHEL-based systems, run:

```
dnf remove zabbix-agent2
dnf install zabbix-agent2
```

On Debian-based systems, run:

```
apt remove zabbix-agent2
apt install zabbix-agent2
```

For more information, see [ZBX-23250](#).

Flipping frontend locales

It has been observed that frontend locales may flip without apparent logic, i. e. some pages (or parts of pages) are displayed in one language while other pages (or parts of pages) in a different language. Typically the problem may appear when there are several users, some of whom use one locale, while others use another.

A known workaround to this is to disable multithreading in PHP and Apache.

The problem is related to how setting the locale works [in PHP](#): locale information is maintained per process, not per thread. So in a multi-thread environment, when there are several projects run by same Apache process, it is possible that the locale gets changed in another thread and that changes how data can be processed in the Zabbix thread.

For more information, please see related problem reports:

- [ZBX-10911](#) (Problem with flipping frontend locales)
- [ZBX-16297](#) (Problem with number processing in graphs using the `bcdiv` function of BC Math functions)

Graphs

Daylight Saving Time

Changes to Daylight Saving Time (DST) result in irregularities when displaying X axis labels (date duplication, date missing, etc).

Sum aggregation

When using **sum aggregation** in a graph for period that is less than one hour, graphs display incorrect (multiplied) values when data come from trends.

Text overlapping

For some frontend languages (e.g., Japanese), local fonts can cause text overlapping in graph legend. To avoid this, use version 2.3.0 (or later) of PHP GD extension.

Log file monitoring

`log []` and `logrt []` items repeatedly reread log file from the beginning if file system is 100% full and the log file is being appended (see [ZBX-10884](#) for more information).

Slow MySQL queries

Zabbix server generates slow `SELECT` queries in case of non-existing values for items. This [issue](#) is known to occur in MySQL 5.6/5.7 versions (for an extended discussion, see [ZBX-10652](#)), and, in specific cases, may also occur in later MySQL versions. A workaround to this is disabling the [index_condition_pushdown](#) or [prefer_ordering_index](#) optimizer in MySQL. Note, however, that this workaround may not fix all issues related to slow queries.

Persistent filter settings from links

When opening a link to Zabbix frontend page that contains filter settings, including the time selector, the filter is automatically saved in the database for the user, replacing the previously saved filter and/or time selector settings for that page. These settings remain active until the user manually updates or resets them.

IPv6 address issue in SNMPv3 traps

Due to a net-snmp bug, IPv6 address may not be correctly displayed when using SNMPv3 in SNMP traps. For more details and a possible workaround, see [ZBX-14541](#).

Trimmed long IPv6 IP address in failed login information

A failed login attempt message will display only the first 39 characters of a stored IP address as that's the character limit in the database field. That means that IPv6 IP addresses longer than 39 characters will be shown incompletely.

Zabbix agent checks on Windows

Non-existing DNS entries in a `Server` parameter of Zabbix agent configuration file (`zabbix_agentd.conf`) may increase Zabbix agent response time on Windows. This happens because Windows DNS caching daemon doesn't cache negative responses for IPv4 addresses. However, for IPv6 addresses negative responses are cached, so a possible workaround to this is disabling IPv4 on the host.

YAML export/import

There are some known issues with YAML **export/import**:

- Error messages are not translatable;
- Valid JSON with a `.yaml` file extension sometimes cannot be imported;
- Unquoted human-readable dates are automatically converted to Unix timestamps.

Setup wizard on SUSE with NGINX and php-fpm

Frontend setup wizard cannot save configuration file on SUSE with NGINX + php-fpm. This is caused by a setting in `/usr/lib/systemd/system/php-fpm.service` unit, which prevents Zabbix from writing to `/etc`. (introduced in [PHP 7.4](#)).

There are two workaround options available:

- Set the [ProtectSystem](#) option to 'true' instead of 'full' in the php-fpm systemd unit.
- Manually save `/etc/zabbix/web/zabbix.conf.php` file.

Authorization header forwarding

In some cases, Apache or NGINX may prevent the Authorization header in API requests from reaching Zabbix. This can cause authentication issues when using Zabbix API or single sign-on (SSO) services, such as SAML with Okta.

To address this, update your web server's configuration.

For **Apache**, if you are using it as a reverse proxy (non-CGI setup), add the following directive to `/etc/httpd/conf/httpd.conf` (on RHEL-based systems) or `/etc/apache2/apache2.conf` (on Debian/Ubuntu):

```
SetEnvIfNoCase ^Authorization$ "(.+)" HTTP_AUTHORIZATION=$1
```

If Apache directly executes scripts to handle requests (e.g., by using `mod_cgi`), add the following directive instead:

```
CGIPassAuth On
```

In contrast, **NGINX** handles the Authorization header automatically. However, if NGINX is acting as a reverse proxy, you may explicitly forward the Authorization header by adding the following directives to `/etc/nginx/nginx.conf` (for your Zabbix frontend location):

```
...
location / {
...
    proxy_set_header Authorization $http_authorization;
    proxy_pass http://backend_server;
...
}
```

After updating the configuration, restart your web server.

For more details, see:

- [ZBX-22952](#)
- [Apache 2.4 + PHP-FPM and Authorization headers](#)
- [SetEnvIfNoCase](#) and [CGIPassAuth](#) directives
- [NGINX Reverse Proxy](#)

Chromium for Zabbix web service on Ubuntu 20

Though in most cases, Zabbix web service can run with Chromium, on Ubuntu 20.04 using Chromium causes the following error:

```
Cannot fetch data: chrome failed to start:cmd_run.go:994:
WARNING: cannot create user data directory: cannot create
"/var/lib/zabbix/snap/chromium/1564": mkdir /var/lib/zabbix: permission denied
Sorry, home directories outside of /home are not currently supported. See https://forum.snapcraft.io/t/112
```

This error occurs because `/var/lib/zabbix` is used as a home directory of user 'zabbix'.

MySQL custom error codes

When Zabbix detects that the backend database is inaccessible, it sends a notification and continues attempting to connect. For certain database engines, specific error codes are recognized. In MySQL, these recognized error codes include:

- CR_CONN_HOST_ERROR
- CR_SERVER_GONE_ERROR
- CR_CONNECTION_ERROR
- CR_SERVER_LOST
- CR_UNKNOWN_HOST
- ER_SERVER_SHUTDOWN
- ER_ACCESS_DENIED_ERROR
- ER_ILLEGAL_GRANT_FOR_TABLE
- ER_TABLEACCESS_DENIED_ERROR
- ER_UNKNOWN_ERROR

Additionally, when using Zabbix with a MySQL installation on Azure, the generic error message *[9002] Some errors occurred* may appear in Zabbix logs. This message is sent by the database to the Zabbix server or proxy. To determine the cause of the error, please consult the Azure logs.

Invalid regular expressions after switching to PCRE2

In Zabbix 6.0 support for PCRE2 has been added. Even though PCRE is still supported, Zabbix installation packages for RHEL 7 and newer, SLES (all versions), Debian 9 and newer, Ubuntu 16.04 and newer have been updated to use PCRE2. While providing many benefits, switching to PCRE2 may cause certain existing PCRE regexp patterns becoming invalid or behaving differently. In particular, this affects the pattern `^[w-\.]`. In order to make this regexp valid again without affecting semantics, change the expression to `^[w-|\.]`. This happens due to the fact that PCRE2 treats the dash sign as a delimiter, creating a range inside a character class.

Geomap widget error

The maps in the Geomap widget may not load correctly, if you have upgraded from an older Zabbix version with NGINX and didn't switch to the new NGINX configuration file during the upgrade.

To fix the issue, you can discard the old configuration file, use the configuration file from the current version package and reconfigure it as described in the [download instructions](#) in section e. *Configure PHP for Zabbix frontend*.

Alternatively, you can manually edit an existing NGINX configuration file (typically, `/etc/zabbix/nginx.conf`). To do so, open the file and locate the following block:

```
location ~ /(api\|/conf[^\.]|include|locale|vendor) {
    deny          all;
    return        404;
}
```

Then, replace this block with:

```
location ~ /(api\|/conf[^\.]|include|locale) {
    deny          all;
    return        404;
}

location /vendor {
    deny          all;
    return        404;
}
```

Use case with global variables shared across webhook calls

As global variables (for example, by doing `global = 1` without a `var`, `let` or `const` declaration) are shared across different webhook calls, the following code will result in the tag value counter gradually increasing:

```
try
{
    aa = aa + 1;
}
catch(e)
{
    aa = 0;
```

```

}

result = {
    'tags': {
        'endpoint': aa
    }
};
return JSON.stringify(result);

```

Using local variables instead of global ones is recommended to make sure that each script operates on its own data and that there are no collisions between simultaneous calls.

Processor groups on Windows

Microsoft documentation states that systems with fewer than 64 logical processors always have a single processor group, Group 0. However, Zabbix users have reported a rare bug [ZBX-20260](#), when there are two processor groups on systems with 64 or less logical processors. This resulted in having the “\Processor(n)” performance counters for only one processor group out of two. The actual root cause of this bug is not known. However, a similar case was described at [stackoverflow.com](#), and the root cause there was in interoperation between BIOS and Windows.

Limits of filtering with utf8mb4 collations

Filters (e.g., in *Data collection* → *Maintenance*) may not function correctly when applied to entities containing certain Unicode characters (e.g., ε , \emptyset). This issue arises due to how the default utf8mb4_bin collation for MySQL or MariaDB databases handles sorting and comparison of Unicode characters.

To address this limitation, users can change the collation of database columns to alternatives such as utf8mb4_0900_bin, utf8mb4_0900_ai_ci, or utf8mb4_unicode_520_ci. Note, however, that changing the collation may cause unexpected behavior in the handling of empty spaces, as well as sorting and filtering for other characters.

For more information on changing collations, see [MySQL documentation](#) or [MariaDB documentation](#). For details on collation differences, see [Unicode Character Sets](#) in MySQL documentation.

Broken autoregistration in Zabbix 7.2.1

In version 7.2.1, Zabbix server crashes upon processing [autoregistration actions](#). As a workaround, disable active agent autoregistration. The issue has been fixed in Zabbix 7.2.2rc1.

Preprocessing manager performance issue in Zabbix 7.2.8

In version 7.2.8, the Zabbix [preprocessing](#) manager may cause high CPU utilization when multiple values are received for a single item at once (such as during log monitoring) and more than one preprocessing worker is configured. As a temporary workaround, set the StartPreprocessors [server/proxy](#) configuration parameter to 1. The issue has been fixed in Zabbix 7.2.9.

Macro functions

Macro functions do not work in script item parameters, browser item script parameters. Fixed in Zabbix 7.2.1.

Access to UI elements with MariaDB 10.5.1–10.5.9

Accessing the Zabbix web frontend with a role other than Super Admin may result in the message: “System error occurred. Please contact Zabbix administrator.”. This issue affects installations using [MariaDB versions](#) 10.5.1 through 10.5.9.

To avoid this issue, update MariaDB to a version later than 10.5.9. For more details, see [ZBX-25746](#).

Incorrect information from nested host groups in maps

Information from nested host groups is incorrectly displayed in maps, for example:

- Host group label displays the problem summary not including all hosts in nested host groups;
- “Host group elements” view does not display a separate map element for each host in the nested host groups;
- Map label displays summary of all problems not including those in nested host groups.

Profiling excessive memory usage with tcmalloc

If you suspect your Zabbix installation is using too much memory, you can use [tcmalloc's](#) memory profiling feature to investigate Zabbix server/proxy memory consumption.

1. When installing Zabbix [from sources](#), configure additional flags:

```
export CFLAGS="-std=gnu99 -g -O0"
```

The `-std=gnu99` flag is required for building Zabbix server, Zabbix proxy, or Zabbix agent. The `-g` flag adds extra debugging information, while `-O0` disables optimizations, which can interfere with tcmalloc's profiling.

2. Set the following environment variables before starting the Zabbix server. These variables tell tcmalloc how to track and report memory usage:

```
LD_PRELOAD="/usr/lib/aarch64-linux-gnu/libtcmalloc.so" \  
HEAPPROFILE=./heap_profile \  
HEAP_PROFILE_ALLOCATION_INTERVAL=0 \  
HEAP_PROFILE_INUSE_INTERVAL=4294967296 \  
HEAPPROFILE_SIGNAL=5 \  
MALLOCSTATS=1 \  
./sbin/zabbix_server -f -c /etc/zabbix/zabbix_server.conf
```

3. Trigger a profile dump by sending signal 5 to the target process. Replace 1234 with the actual process ID (PID):

```
kill -5 1234
```

4. Print the generated profile:

```
pprof-symbolize -text ./sbin/zabbix_server ./heap_profile.0001.heap
```

Using local file ./sbin/zabbix_server.

Using local file ./heap_profile.0001.heap.

Total: 1078.1 MB

| | | | | | |
|--------|-------|--------|--------|-------|----------------------------------|
| 1076.8 | 99.9% | 99.9% | 1076.8 | 99.9% | zbx_malloc2 |
| 1.0 | 0.1% | 100.0% | 1.0 | 0.1% | __GI___strdup |
| 0.2 | 0.0% | 100.0% | 0.2 | 0.0% | CRYPTO_zalloc@@OPENSSL_3.0.0 |

MySQL 8.0 Group Replication in multi-primary mode

When using MySQL 8.0 Group Replication in multi-primary mode, you may encounter an error during transaction commits similar to the following:

```
1531697:20250128:064734.697 query [txnlev:1] [update alerts set status=1,retries=0,error='' where alertid=  
1531697:20250128:064734.713 query [txnlev:1] [commit;]  
1531697:20250128:064734.753 [Z3005] query failed: [3101] Plugin instructed the server to rollback the curr
```

This error appears to be triggered by issues with rollback operations involving foreign key constraints.

See also:

- [ZBX-26060](#) for the related problem report.
- [MySQL Bug #96758 "Rollbacks with Foreign Keys on single node"](#) for the upstream issue.

1 Compilation issues

These are the known issues regarding Zabbix compilation from sources. For all other cases, see the [Known issues](#) page.

Compiling Zabbix agent on HP-UX

If you install the PCRE library from the popular HP-UX package site <http://hpx.connect.org.uk> (for example, from file pcre-8.42-ia64_64-11.31.depot), only the 64-bit version of the library will be installed in the /usr/local/lib/hpux64 directory.

In this case, for successful agent compilation, a customized option is needed for the configure script, for example:

```
CFLAGS="+DD64" ./configure --enable-agent --with-libpcre-include=/usr/local/include --with-libpcre-lib=/usr
```

and **update** trigger expressions to use them:

Trig_228:

```
find(/Zabbix server/vfs.file.contents[/tmp/ONE],1m:now,"regexp",{228_BACKSLASHES_A})
```

Trig_232:

```
find(/Zabbix server/vfs.file.contents[/tmp/ONE],1m:now,"regexp",{232_BACKSLASHES_A})
```

Now both triggers work the same way as before - only Trig_228 is **firing**.

There are no issues with the calculated items, but they could also be updated for consistency:

Calc_228:

```
find(/Zabbix server/vfs.file.contents[/tmp/ONE],1m:now,"regexp",{228_BACKSLASHES_A})
```

Calc_232:

```
find(/Zabbix server/vfs.file.contents[/tmp/ONE],1m:now,"regexp",{232_BACKSLASHES_A})
```

9 Template changes

This page lists all changes to the stock templates that are shipped with Zabbix.

Upgrading to the latest Zabbix version will not automatically upgrade the templates used. It is suggested to modify the templates in existing installations by downloading the latest templates from the [Zabbix Git repository](#) and **importing** them manually into Zabbix.

If templates with the same names already exist, the *Delete missing* options should be checked when importing to achieve a clean import. This way, the old items that are no longer in the updated template will be removed (note that it will mean losing history of these old items).

Note:

Please be informed that since Zabbix 6.0, all templates follow an updated format, which may impact the import of pre-6.0 templates. For more information, see [Template changes in 6.0](#).

Changes in 7.2.0 Updated templates

- *VMware* and *VMware FQDN* templates now automatically suppress all problems if a hypervisor is in maintenance mode. To disable problem suppression, set the `{$VMWARE.HYPERVISOR.MAINTENANCE}` macro value to 0.

Changes in 7.2.1 New templates

- [Juniper MX by SNMP](#), a template for the Juniper MX Series.

Changes in 7.2.4 New templates

- The [Azure by HTTP](#) template set has been supplemented with the template *Azure SQL Managed Instance by HTTP*.
- [Palo Alto PA-440 by HTTP](#), a template that uses script items to collect metrics using the PAN-OS XML API.

Updated templates

- All [Dell HTTP and SNMP](#) templates have been updated with improvements, including fixes for items, macros, and scripts.
- The templates [MSSQL by ODBC](#) and [MSSQL by Zabbix agent 2](#) have been updated with filters to include or exclude discovered quorum members by name as well as a service filter that allows filtering by cluster name to exclude empty clusters. Please see [Breaking changes](#) for additional information on *MSSQL by Zabbix agent 2*.

Changes in 7.2.5 New templates

- The [Azure by HTTP](#) template set has been supplemented with the template *Azure Microsoft SQL DTU Database by HTTP*.
- The template set [Zabbix server health](#) has been supplemented with the templates *Zabbix server health by Zabbix agent*, *Zabbix server health by Zabbix agent active*, and [Zabbix proxy health](#) - with *Zabbix proxy health by Zabbix agent* and *Zabbix proxy health by Zabbix agent active*, enabling the monitoring of internal Zabbix metrics via Zabbix agent.

Updated templates

- The templates within the [VMware](#) and [VMware FQDN](#) template sets have been updated with fixes for datastore item prototypes. In the template *VMware Guest*, an incorrect preprocessing multiplier has been fixed in the item for virtual machine network utilization, and a problem has been fixed in the discovery rule for mounted filesystems.

Changes in 7.2.6 New templates

- [Pure Storage FlashArray v1 and v2 by HTTP](#), a template set for monitoring Pure Storage FlashArray systems.
- [Juniper MX by NETCONF](#), a template for monitoring Juniper MX Series devices using NETCONF.

Updated templates

- [MySQL by Zabbix agent](#), [MySQL by Zabbix agent 2](#), [MySQL by Zabbix agent active](#), [MySQL by Zabbix agent 2 active](#), and [MySQL by ODBC](#) have been updated with a fix for the buffer pool efficiency formula.
- In the template [MSSQL by ODBC](#), the item "Get last backup" has been updated to exclude non-existing databases from the query.

Changes in 7.2.7 New templates

- The [Azure by HTTP](#) template set has been supplemented with the template *Azure Backup Jobs by HTTP*.

Updated templates

- [PostgreSQL by Zabbix agent 2](#) has been updated for compatibility with PostgreSQL 17 and now uses the new `pg_stat_checkpoint` system view for checkpoint statistics (previously `pg_stat_bgwriter`).

Changes in 7.2.8 Updated templates

- [Oracle by ODBC](#) and [Oracle by Zabbix agent 2](#) have been updated to query PDB and tablespace statistics using the container ID instead of the container name.

10 Upgrade notes for 7.2.0

These notes are for upgrading from Zabbix 7.0.x to Zabbix 7.2.0.

All notes are grouped into:

- **Breaking changes** - changes that may break existing installations and other critical information related to the upgrade process
- **Other** - all remaining information describing the changes in Zabbix functionality

See also:

- [Upgrade procedure](#) for all relevant information about upgrading from versions before Zabbix 7.0.0;
- [Upgrading HA cluster](#) for instructions on upgrading servers in a **high-availability** (HA) cluster.

Upgrade process

To complete a successful Zabbix server upgrade on MySQL/MariaDB, you may require to set `GLOBAL log_bin_trust_function_creators = 1` in MySQL if binary logging is enabled, there are no superuser privileges and `log_bin_trust_function_creators = 1` is not set in MySQL configuration file.

To set the variable using the MySQL console, run:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

Once the upgrade has been successfully completed, this option can be disabled:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 0;
```

Breaking changes Oracle DB dropped

The support for Oracle as a backend database, deprecated since Zabbix 7.0, has been removed.

Escaping of backslashes in history function parameters

Proper escaping of backslashes has been added in history function string parameters since Zabbix 7.0.0.

As additional backslashes are added during the upgrade from pre-7.0 Zabbix versions, this leads to longer parameters which may result in broken trigger functions if the parameter length exceeds the maximum data size of 255 characters.

To avoid this problem it is suggested to manually move long parameters into user macros before the upgrade.

Note that since Zabbix 7.2.5 additional checks for the resulting parameter length have been added for upgrades from pre-7.0 Zabbix versions. If the resulting length exceeds the maximum size, such parameters are **not upgraded** while printing a warning in the logs asking users to fix the listed parameters manually.

See also [escaping-related upgrade issues](#).

Frontend file directory changed during package installation

The frontend file directory has been moved from `/usr/share/zabbix` to `/usr/share/zabbix/ui`.

Note that during the upgrade the web server configuration file, if it contains custom changes (typically with Nginx), will not be automatically overwritten with the updated file containing the new paths. You will need to back up the old config file and then overwrite the old config file with the new one, for example, on RedHat based systems:

```
cp /etc/nginx/conf.d/zabbix.conf.rpmnew /etc/nginx/conf.d/zabbix.conf
```

and then edit the updated configuration file (`/etc/nginx/conf.d/zabbix.conf`) manually to restore the old configuration.

Repository structure

[Zabbix repository](#) now contains Zabbix package files in the folders `.../7.2/stable/` (released versions) and `.../7.2/unstable/` (pre-release packages for alpha, beta, and release candidate versions) instead of `.../7.1/` for unstable versions and `.../7.2/` for stable versions.

The *zabbix-release* packages, which can be used for both stable and unstable releases, are provided separately in the `7.2/release` folder.

For 7.2 and newer versions, packages from the `non-supported` folder are moved to the `third-party` folder, which now contains customized packages for RHEL and its derivative distributions.

A new key `B5333005` is used to sign everything, except for [zabbix-tools](#) repo, which has its own dedicated `zabbix-tools` key.

Loadable plugin executables relocated

When upgrading Zabbix agent 2 from packages, **loadable plugin** executables are moved to a new location - from `/usr/sbin/zabbix-agent2` to `/usr/libexec/zabbix` (for SLES, `/usr/lib/zabbix`).

After upgrading, you may need to update any previously modified plugin configuration files to reflect the new location. For example, update the **MSSQL plugin** `Plugins.MSSQL.System.Path` parameter to `/usr/libexec/zabbix/zabbix-agent2-plugin-mssql`.

auth API property dropped

The support for the `auth` API property, deprecated since Zabbix 6.4, has been removed. For alternative API authorization methods, see [Authentication](#). For other API changes, see [Appendix 2. Changes from 7.0 to 7.2](#).

Items turn unsupported with no pollers configured

A check for poller has been added when an item is added to configuration cache and when item type changes. This check has been added for agent, SNMP agent, HTTP agent, browser, script, JMX monitoring, ODBC monitor, and IPMI items.

If no pollers are configured, the items will turn unsupported instead of being simply ignored. This change does not affect item behavior when executed manually ("Test item") or script execution.

Other Naming

When configuring an **item history** widget:

- *Columns* parameter has been renamed to *Items*
- *Data* column in the selected item list has been renamed to *Item*

Data overview widget migrated to Top items

A new **Top items** widget has been added, replacing the functionality of the deprecated *Data overview* widget. Existing *Data overview* widgets will be migrated to *Top items*.

Note that if previously the *Max number of columns and rows in overview tables* value was set above 100 in *Administration -> General -> GUI*, now host/item value records will be limited to 100.

Low-level discovery

The performance of low-level discovery has been improved, as a result of which the previous limits of 29999 **dependent items** per master item and 3 dependency levels have been removed.

11 Upgrade notes for 7.2.1

Warning! In this version, Zabbix server crashes upon processing **autoregistration actions**. As a workaround, disable active agent autoregistration. The issue has been fixed in Zabbix 7.2.2rc1.

12 Upgrade notes for 7.2.2

This minor version does not have any upgrade notes.

13 Upgrade notes for 7.2.3

Breaking changes Java 11 required for Java gateway

Zabbix Java gateway now requires Java 11 for runtime (building from source is still possible with Java 8), due to updated minimum logback library versions:

| Library | New minimum version | Old minimum version |
|---------------------------------|---------------------|---------------------|
| logback-classic | 1.5.16 | 1.2.9 |
| logback-core | 1.5.16 | 1.2.9 |
| slf4j-api | 2.0.16 | 1.7.32 |

14 Upgrade notes for 7.2.4

Breaking changes MSSQL Zabbix agent 2 plugin update

The template [MSSQL by Zabbix agent 2](#) has been updated with filters to include or exclude discovered quorum members by name as well as a service filter that allows filtering by cluster name to exclude empty clusters. To have the template work without errors, the **MSSQL Zabbix agent 2 plugin** must be updated to a version equal to or above 7.2.4.

Other Improved DNS resolution handling for agent pollers

In this version, the agent poller will attempt to connect to all addresses returned by the DNS lookup. This improvement ensures that if one IP address is unreachable, the agent poller can try the next one, increasing the likelihood of a successful connection.

15 Upgrade notes for 7.2.5

Asynchronous DNS resolution

The agent poller and SNMP poller can now be configured to use the *c-ares* library (version 1.16.0 or newer) instead of the *libevent* DNS resolver, providing potentially faster and more flexible DNS resolution.

If you want to use c-ares library, configure Zabbix with the `--with-ares` option:

```
--with-ares[=ARG]      use c-ares library [default=no],
--with-ares-include=DIR use c-ares include headers from given path.
--with-ares-lib=DIR     use c-ares libraries from given path.
```

Note that starting from c-ares 1.31.0, DNS caching is enabled by default.

Escaping of backslashes in history function parameters

Proper escaping of backslashes has been added in history function string parameters since Zabbix 7.0.0.

As additional backslashes are added during the upgrade from pre-7.0 Zabbix versions, this leads to longer parameters which may result in broken trigger functions if the parameter length exceeds the maximum data size of 255 characters.

To avoid this problem it is suggested to manually move long parameters into user macros before the upgrade.

Note that since Zabbix 7.2.5 additional checks for the resulting parameter length have been added for upgrades from pre-7.0 Zabbix versions. If the resulting length exceeds the maximum size, such parameters are **not upgraded** while printing a warning in the logs asking users to fix the listed parameters manually.

See also [escaping-related upgrade issues](#).

16 Upgrade notes for 7.2.6

This minor version does not have any upgrade notes.

17 Upgrade notes for 7.2.7

Secret macro resolution

Secret user macro values will now remain masked in **locations** that support secret macro resolution if they are referenced indirectly. For example, `{ITEM.KEY}`, `{ITEM.KEY<1-9>}`, `{LLDRULE.KEY}` built-in macros used in media types (Script or Webhook parameters) will resolve to item keys containing masked secret macros, such as `net.tcp.port[*****,*****]` instead of `net.tcp.port[192.0.2.0,80]`.

Interface availability calculation

Host interface availability overall status calculation is now only affected by Zabbix agent, IPMI agent, JMX agent, or SNMP agent items. Other item types using interface like simple checks can't change the interface status so they are now excluded from the overall status calculation.

18 Upgrade notes for 7.2.8

Warning:

In this version, the Zabbix **preprocessing** manager may cause high CPU utilization when multiple values are received for a single item at once (such as during log monitoring) and more than one preprocessing worker is configured. As a temporary workaround, set the `StartPreprocessors` **server/proxy** configuration parameter to 1. The issue has been fixed in Zabbix 7.2.9.

 We recommend upgrading to Zabbix 7.2.9 as soon as possible.

SNMP walk and get retries increased

SNMP agent **walk** and **get** items now make up to 5 retries (instead of 1) to retrieve all values if previous attempts time out or fail. Each retry resets the timeout and resumes from the last successful request, improving data reliability in case of packet loss or delayed responses during SNMP data collection.

Consider setting a low timeout in the **item configuration** form to avoid long delays if the device is unreachable (e.g., 3-second timeout can result in 15-second wait time).

Minimum supported Go version

The minimum supported Go version has been raised from 1.21 to 1.23.

If you previously built Zabbix **agent 2**, **agent 2 loadable plugins**, or **web service** from source using a Go version older than 1.23, it is recommended to rebuild these components using a **supported Go version** to receive the latest security updates and bug fixes. Components built with an older Go version will continue to work, but **upgrading** them will require a newer Go environment.

Database connection parameters

DBPort and **DBSocket** are now mutually exclusive. When specifying database connection parameters, you may define either **DBPort** or **DBSocket**, or leave both undefined to use defaults.

19 Upgrade notes for 7.2.9

This minor version has no upgrade notes.

20 Upgrade notes for 7.2.10

This minor version has no upgrade notes.

5 Quickstart

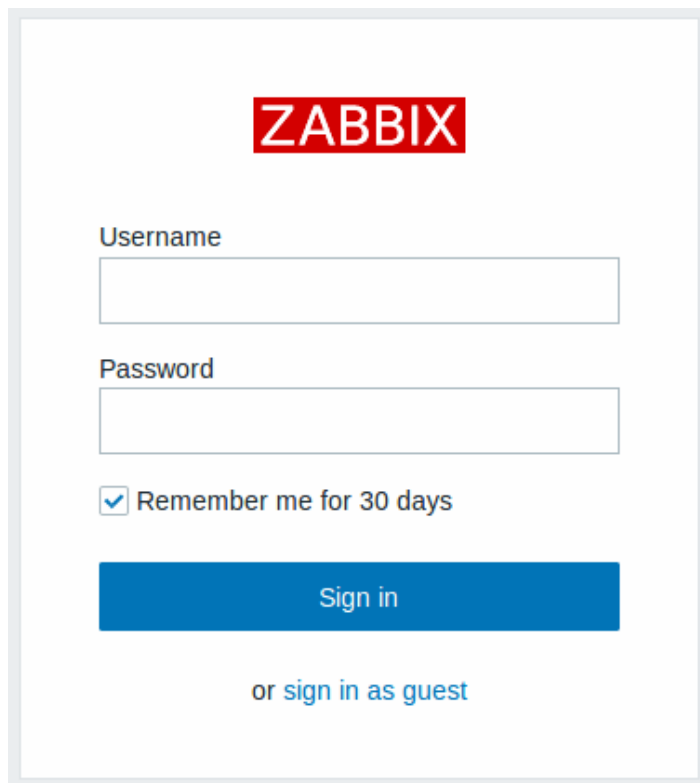

Please use the sidebar to access content in the Quickstart section.

1 Login and configuring user

Overview

In this section, you will learn how to log in and set up a system user in Zabbix.

Login

The image shows the Zabbix login interface. At the top, the 'ZABBIX' logo is displayed in white text on a red rectangular background. Below the logo, there are two input fields: the first is labeled 'Username' and the second is labeled 'Password'. Under the password field, there is a checkbox that is checked, followed by the text 'Remember me for 30 days'. Below these elements is a solid blue button with the text 'Sign in' in white. At the bottom of the form, there is a link that says 'or sign in as guest' in blue text.

This is the Zabbix welcome screen. Enter the user name **Admin** with password **zabbix** to log in as a **Zabbix superuser**. Access to all menu sections will be granted.

For security reasons, it is strongly recommended to change the default password for the Admin account immediately after the first login.

Persistent login

To stay logged in for up to 30 days, select *Remember for 30 days* before clicking *Sign in*.

Remember for 30 days enabled:

- Your session remains active for 30 days.

- **Auto-logout** is overridden, keeping you signed in until the period ends.
- You will be auto-logged in on future visits within 30 days without re-entering credentials.

Remember for 30 days disabled:

- Any previously enabled auto-login is cleared.
- Session will expire according to the configured *Auto-logout* interval.

Protection against brute force attacks

In case of five consecutive failed login attempts, Zabbix interface will pause for 30 seconds in order to prevent brute force and dictionary attacks.

The IP address of a failed login attempt will be displayed after a successful login.

Adding user

To view information about users, go to *Users > Users* in the sidebar's vertical menu.

Users

Create user

| Username | Name | Last name | User role | Groups | Is online? | Login | Frontend access | API access | Debug mode | Status | Provisioned | Info |

Adding permissions

By default, a new user has no permissions to access hosts and templates. To grant the user rights, click on the group of the user in the *Groups* column (in this case - 'Zabbix administrators'). In the *User groups* properties form, go to the *Host permissions* tab to assign permissions to host groups. Click on [Add](#) for the host group selection field to be displayed:

User groups

User group Template permissions **Host permissions** Problem tag filter

Permissions

Host groups

type here to search

Select Read-write Read Deny Remove

Add

Update Delete Cancel

Then click on *Select* next to the field to see the list of the host groups. This user is to have read-only access to *Linux servers* group, so mark the appropriate checkbox in the list and click on *Select* to confirm your choice.

Host groups

☐ Name

☐ Applications

☐ Databases

☐ Discovered hosts

☐ Hypervisors

☒ Linux servers

☐ Virtual machines

☐ Zabbix servers

Select Cancel

Click the *Read* button to set the permission level and then *Update* to save the changes made to the user group configuration.

To grant permissions to templates, you will need to switch to the *Template permissions* tab and specify template groups. The steps are identical to assigning permissions to host groups. An overview of templates is available in the **New template** section of this Quickstart.

Attention:

In Zabbix, access rights to hosts and templates are assigned to **user groups**, not individual users.

Done! You may try to log in using the credentials of the new user.

2 New host

Overview

In this section you will learn how to set up a new host.

A host in Zabbix is a networked entity (physical, virtual) that you wish to monitor. The definition of what can be a "host" in Zabbix is quite flexible. It can be a physical server, a network switch, a virtual machine or some application.

Adding host

Information about configured hosts in Zabbix is available in *Data collection > Hosts* as well as *Monitoring > Hosts* menu sections. There is already one pre-defined host, called "Zabbix server", but we want to learn adding another.

To add a new host, click on *Create host*. This will present us with a host configuration form.

New host

Type

IP address

DNS name

Agent

[Add](#)

Description

All mandatory input fields are marked with a red asterisk.

The bare minimum to enter here is:

Host name

- Enter a host name. Alphanumerics, spaces, dots, dashes and underscores are allowed.

Host groups

- Select one or several existing groups by clicking *Select* button or enter a non-existing group name to create a new group.

Note:

All access permissions are assigned to host groups, not individual hosts. That is why a host must belong to at least one group.

Interfaces: IP address

- Although not a required field technically, a host interface is necessary for collecting certain metrics. To use Zabbix agent passive checks, specify the agent's IP or DNS in this field. Note that you should also specify Zabbix server's IP or DNS in the Zabbix agent configuration file 'Server' directive. If Zabbix agent and Zabbix server are installed on the same machine, you need to specify the same IP/DNS in both places.

Other options will suit us with their defaults for now.

When done, click *Add*. Your new host should be visible in the host list.

| <input type="checkbox"/> | Name ▲ | Items | Triggers | Graphs | Discovery | Web | Interface | Proxy | Templates | Status | Availability | Agent encryption | Info | Tags |
|--------------------------|----------|-------|----------|--------|-----------|-----|-----------------|-------|-----------|---------|--------------|------------------|------|------|
| <input type="checkbox"/> | New host | Items | Triggers | Graphs | Discovery | Web | 127.0.0.1:10050 | | | Enabled | ZBX | None | | |

The Availability column contains indicators of host availability per each interface. We have defined a Zabbix agent interface, so we can use the agent availability icon (with 'ZBX' on it) to understand host availability:

-  - host status has not been established; no metric check has happened yet
 -  - host is available, a metric check has been successful
 -  - host is unavailable, a metric check has failed (move your mouse cursor over the icon to see the error message).
- There might be some error with communication, possibly caused by incorrect interface credentials. Check that Zabbix server is running, and try refreshing the page later as well.

3 New item

Overview

In this section, you will learn how to set up an item.

Items are the basis of gathering data in Zabbix. Without items, there is no data - because only an item defines a single metric or what kind of data to collect from a host.

Adding item

All items are grouped around hosts. That is why to configure a sample item we go to *Data collection > Hosts* and find the "New host" we have created.

Click on the *Items* link in the row of "New host", and then click on *Create item*. This will present us with an item definition form.

The screenshot shows the 'Create item' form in Zabbix. The form is titled 'Item' and has tabs for 'Tags' and 'Preprocessing'. The 'Preprocessing' tab is selected. The form contains the following fields and options:

- Name:** CPU load (mandatory, marked with a red asterisk)
- Type:** Zabbix agent (dropdown)
- Key:** system.cpu.load (mandatory, marked with a red asterisk). There is a 'Select' button next to it.
- Type of information:** Numeric (float) (dropdown)
- Host interface:** 127.0.0.1:10050 (mandatory, marked with a red asterisk, dropdown)
- Units:** (empty text field)
- Update interval:** 1m (mandatory, marked with a red asterisk)
- Custom intervals:** A table with columns: Type, Interval, Period, Action.
 - Row 1: Flexible, Scheduling, 50s, 1-7,00:00-24:00, Remove
 - Row 2: Add
- Timeout:** Global, Override, 3s (mandatory, marked with a red asterisk). There is a 'Timeouts' link next to it.
- History:** Do not store, Store up to, 90d (mandatory, marked with a red asterisk)
- Trends:** Do not store, Store up to, 365d (mandatory, marked with a red asterisk)
- Value mapping:** type here to search (mandatory, marked with a red asterisk). There is a 'Select' button next to it.
- Populates host inventory field:** -None- (dropdown)
- Description:** (empty text area)
- Enabled:** ☒
- Buttons:** Add, Test, Cancel

All mandatory input fields are marked with a red asterisk.

For our sample item, the essential information to enter is:

Name

- Enter *CPU load* as the value. This will be the item name displayed in lists and elsewhere.

Key

- Manually enter *system.cpu.load* as the value. This is the technical name of an item that identifies the type of information that will be gathered. The particular key is just one of **pre-defined keys** that come with Zabbix agent.

Type of information

- This attribute defines the format of the expected data. For the *system.cpu.load* key, this field will be automatically set to *Numeric (float)*.

Note:

You may also want to reduce the number of days **item history** will be kept, to 7 or 14. This is good practice to relieve the database from keeping lots of historical values.

Other options will suit us with their defaults for now.

When done, click **Add**. The new item should appear in the item list, and you should see a success message.

Viewing data

With an item defined, you might be curious if it is actually gathering data. For that, go to **Monitoring > Latest data**, select 'New host' in the filter and click on **Apply**.

≡ Latest data Filter

| Host | Name | Last check | Last value | Change | Tags |
|----------|----------|-----------------------|------------|--------|-----------------------|
| New host | CPU load | 05/24/2021 10:40:5... | 1.17 | -0.11 | Graph |

0 selected Display stacked graph Display graph

With that said, it may take up to 60 seconds for the first data to arrive. That, by default, is how often the server reads configuration changes and picks up new items to execute.

If you see no value in the 'Change' column, maybe only one value has been received so far. Wait 30 seconds for another value to arrive.

If you do not see information about the item as in the screenshot, make sure that:

- you have filled out the item 'Key' and 'Type of information' fields exactly as in the screenshot;
- both the agent and the server are running;
- host status is 'Monitored' and its availability icon is green;
- the host selected in the host filter is correct;
- the item is enabled.

Graphs

With the item working for a while, it might be time to see something visual. **Simple graphs** are available for any monitored numeric item without any additional configuration. These graphs are generated on runtime.

To view the graph, go to **Monitoring > Latest data** and click on the 'Graph' link next to the item.

4 New trigger

Overview

In this section you will learn how to set up a trigger.

Items only collect data. To automatically evaluate incoming data we need to define triggers. A trigger contains an expression that defines a threshold of what is an acceptable level for the data.

If that level is surpassed by the incoming data, a trigger will "fire" or go into a 'Problem' state - letting us know that something has happened that may require attention. If the level is acceptable again, trigger returns to an 'Ok' state.

Adding trigger

To configure a trigger for our item, go to *Data collection > Hosts*, find 'New host' and click on *Triggers* next to it and then on *Create trigger*. This presents us with a trigger definition form.

The screenshot shows the 'New trigger' form with the following details:

- Name:** CPU load too high on 'New host' for 3 minutes
- Event name:** CPU load too high on 'New host' for 3 minutes
- Operational data:** (empty field)
- Severity:** Not classified (selected), Information, Warning, Average, High, Disaster
- Expression:** avg(/New host/system.cpu.load,3m)>2
- OK event generation:** Expression (selected), Recovery expression, None
- PROBLEM event generation mode:** Single (selected), Multiple
- OK event closes:** All problems (selected), All problems if tag values match
- Allow manual close:** ☐
- Menu entry name:** Trigger URL
- Menu entry URL:** (empty field)
- Description:** (empty text area)
- Enabled:** ☒

For our trigger, the essential information to enter here is:

Name

- Enter *CPU load too high on 'New host' for 3 minutes* as the value. This will be the trigger name displayed in lists and elsewhere.

Expression

- Enter: `avg(/New host/system.cpu.load,3m)>2`

This is the trigger expression. Make sure that the expression is entered right, down to the last symbol. The item key here (system.cpu.load) is used to refer to the item. This particular expression basically says that the problem threshold is exceeded when the CPU load average value for 3 minutes is over 2. You can learn more about the [syntax of trigger expressions](#).

When done, click *Add*. The new trigger should appear in the trigger list.

Displaying trigger status

With a trigger defined, you might be interested to see its status.

If the CPU load has exceeded the threshold level you defined in the trigger, the problem will be displayed in *Monitoring > Problems*.

| Time | <input type="checkbox"/> | Severity | Recovery time | Status | Info | Host ▲ | Problem | Operational data | Duration |
|----------|--------------------------|----------------|---------------|---------|------|----------|---|------------------|----------|
| 16:23:06 | <input type="checkbox"/> | Not classified | | PROBLEM | | New host | CPU load too high on "New host" for 3 minutes | 6.6 | 56s |

The flashing in the status column indicates a recent change of trigger status, one that has taken place in the last 30 minutes.

5 Receiving problem notification

Overview

In this section you will learn how to set up alerting in the form of notifications in Zabbix.

With items collecting data and triggers designed to "fire" upon problem situations, it would also be useful to have some alerting mechanism in place that would notify us about important events even when we are not directly looking at Zabbix frontend.

This is what notifications do. Email being the most popular delivery method for problem notifications, we will learn how to set up an email notification.

Email settings

Initially there are several predefined notification **delivery methods** in Zabbix. **Email** is one of those.

To configure email settings, go to *Alerts > Media types* and click on *Email* in the list of pre-defined media types.

≡ Media types

| <input type="checkbox"/> | Name ▲ | Type | Status | Used in actions | Details |
|--------------------------|------------|---------|---------|-----------------|---------------------------------|
| <input type="checkbox"/> | Email | Email | Enabled | | SMTP server: "mail.zabbix.com", |
| <input type="checkbox"/> | Mattermost | Webhook | Enabled | | |
| <input type="checkbox"/> | Opsgenie | Webhook | Enabled | | |

This will present us with the email settings definition form.

New media type

Description

Enabled
☒

Add
Cancel

All mandatory input fields are marked with a red asterisk.

In the *Media type* tab, set the values of SMTP server, SMTP helo and SMTP email to the appropriate for your environment.

Note:

'SMTP email' will be used as the 'From' address for the notifications sent from Zabbix.

Next, it is required to define the content of the problem message. The content is defined by means of a message template, configured in the *Message templates* tab.

Click on *Add* to create a message template, and select *Problem* as the message type.

Message template
X

Message type
Problem

Subject
Problem: {EVENT.NAME}

Message
Problem started at {EVENT.TIME} on {EVENT.DATE}
Problem name: {EVENT.NAME}
Host: {HOST.NAME}
Severity: {EVENT.SEVERITY}
Operational data: {EVENT.OPDATA}
Original problem ID: {EVENT.ID}
{TRIGGER.URL}

Add
Cancel

Click on *Add* when ready and save the form.

Now you have configured 'Email' as a working media type. The media type must also be linked to users by defining specific delivery addresses (like we did when [configuring a new user](#)), otherwise it will not be used.

New action

Delivering notifications is one of the things [actions](#) do in Zabbix. Therefore, to set up a notification, go to *Alerts > Actions > Trigger actions* and click on *Create action*.

≡ Actions

The screenshot shows the 'Create Action' form in Zabbix. The 'Action' tab is active. The 'Name' field is required (marked with a red asterisk) and contains the text 'Test action'. Below this is the 'Conditions' section, which contains a table with two columns: 'Label' and 'Name'. There is an 'Add' button below the table. The 'Enabled' checkbox is checked. A message below the checkbox states: '* At least one operation must exist.' At the bottom of the form are two buttons: 'Add' and 'Cancel'.

All mandatory input fields are marked with a red asterisk.

In this form, enter a name for the action.

In the most simple case, if we do not add any more specific [conditions](#), the action will be taken upon any trigger change from 'Ok' to 'Problem'.

We still should define what the action should do - and that is done in the *Operations* tab. Click on *Add* in the Operations block, which opens a new operation form.

Operation details

×

Operation

Pause operations for suppressed problems

☒

Operations

| Steps | Details | Start in | Duration |
|-------|--|-------------|----------|
| 1 | Send message to users: user (New User) via Email | Immediately | Default |

Add

That is all for a simple action configuration, so click *Add* in the action form.

Receiving notification

Now, with delivering notifications configured, it would be fun to actually receive one. To help with that, we might on purpose increase the load on our host - so that our **trigger** "fires" and we receive a problem notification.

Open the console on your host and run:

```
cat /dev/urandom | md5sum
```

You may run one or several of [these processes](#).

Now go to *Monitoring > Latest data* and see how the values of 'CPU Load' have increased. Remember, for our trigger to *fire*, the 'CPU Load' value has to go over '2' for 3 minutes running. Once it does:

- in *Monitoring > Problems* you should see the trigger with a flashing 'Problem' status
- you should receive a problem notification in your email

Attention:

If notifications do not work:

- verify once again that both the email settings and the action have been configured properly
- make sure the user you created has at least read permissions on the host which generated the event, as noted in the *Adding user* step. The user, being part of the 'Zabbix administrators' user group must have at least read access to 'Linux servers' host group that our host belongs to.
- Additionally, you can check out the action log by going to *Reports > Action log*.

6 New template

Overview

In this section you will learn how to set up a template.

Previously we learned how to set up an item, a trigger and how to get a problem notification for the host.

While all of these steps offer a great deal of flexibility in themselves, it may appear like a lot of steps to take if needed for, say, a thousand hosts. Some automation would be handy.

This is where templates come to help. Templates allow to group useful items, triggers and other entities so that those can be reused again and again by applying to hosts in a single step.

When a template is linked to a host, the host inherits all entities of the template. So, basically a pre-prepared bunch of checks can be applied very quickly.

Adding template

To start working with templates, we must first create one. To do that, in *Data collection > Templates* click on *Create template*. This will bring up a template configuration form.

The screenshot shows the 'New template' dialog box. It has four tabs: 'Template' (selected), 'Tags', 'Macros', and 'Value mapping'. Under the 'Template' tab, there are several input fields:

- 'Template name' is a required field (marked with a red asterisk) containing the text 'New template'.
- 'Visible name' is an optional field containing 'New template'.
- 'Templates' is a searchable list field with the placeholder 'type here to search' and a 'Select' button.
- 'Template groups' is a required field (marked with a red asterisk) containing 'Templates' with a dropdown arrow, and a 'Select' button.
- 'Description' is a large text area.

 At the bottom right of the dialog are 'Add' and 'Cancel' buttons.

All mandatory input fields are marked with a red asterisk.

The required parameters to enter here are:

Template name

- Enter a template name. Alpha-numericals, spaces and underscores are allowed.

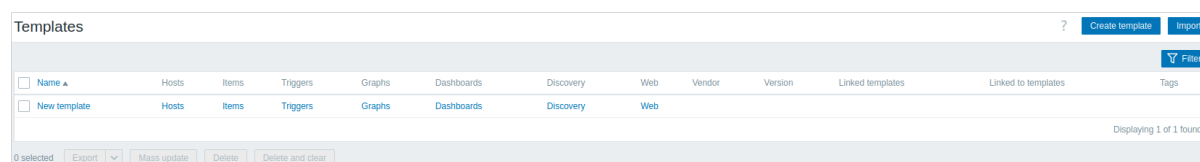

Template groups

- Select one or several groups by clicking *Select* button. The template must belong to a group.

Note:

Access permissions to template groups are assigned in the *user group* configuration on the **Template permissions** tab in the same way as host permissions. All access permissions are assigned to groups, not individual templates, that's why including the template into at least one group is mandatory.

When done, click *Add*. Your new template should be visible in the list of templates. You can also use the **filter** to find your template.

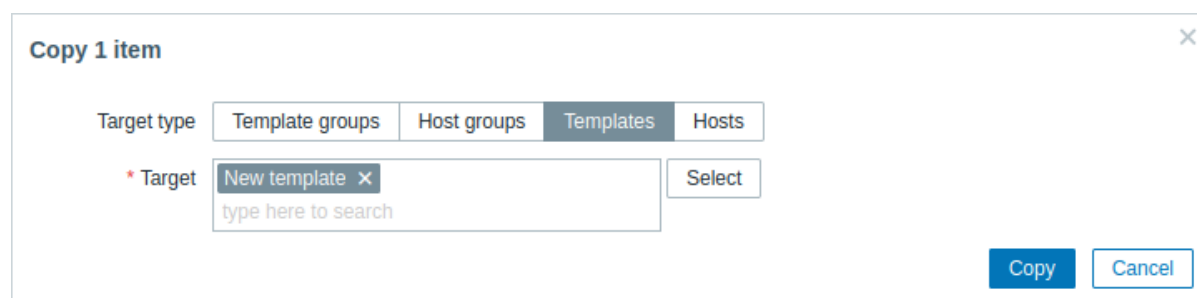

As you may see, the template is there, but it holds nothing in it - no items, triggers or other entities.

Adding item to template

To add an item to the template, open the item list for 'New host' by navigating to *Data collection* → *Hosts* and clicking *Items* next to 'New host'.

Then:

- Mark the checkbox of the 'CPU Load' item in the list.
- Click on *Copy* below the list.
- Select the *Templates* tab.
- Select the template to copy the item to.

All mandatory input fields are marked with a red asterisk.

- Click on *Copy*.

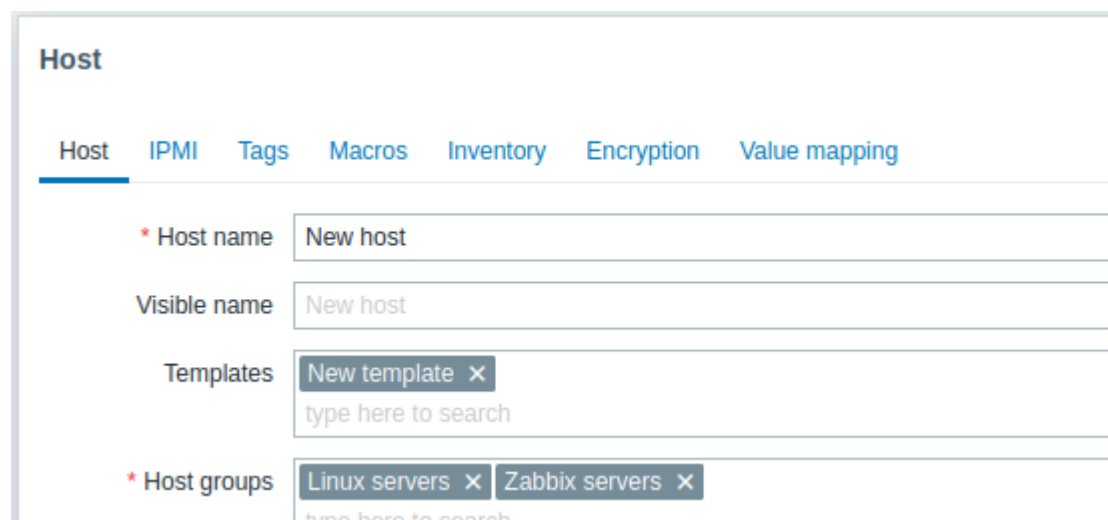

If you now go to *Data collection* > *Templates*, 'New template' should have one new item in it.

We will stop at one item only for now, but similarly you can add any other items, triggers or other entities to the template until it's a fairly complete set of entities for given purpose (monitoring OS, monitoring single application).

Linking template to host

With a template ready, it only remains to add it to a host. For that, go to *Data collection* > *Hosts*, click on 'New host' to open its configuration form and find the **Templates** field.

Start typing *New template* in the *Templates* field. The name of template we have created should appear in the dropdown list. Scroll down to select. See that it appears in the *Templates* field.

Click *Update* in the form to save the changes. The template is now added to the host, with all entities that it holds.

This way it can be applied to any other host as well. Any changes to the items, triggers and other entities at the template level will propagate to the hosts the template is linked to.

Linking pre-defined templates to hosts

As you may have noticed, Zabbix comes with a set of predefined templates for various OS, devices and applications. To get started with monitoring very quickly, you may link the appropriate one of them to a host, but beware that these templates need to be fine-tuned for your environment. Some checks may not be needed, and polling intervals may be way too frequent.

More information about [templates](#) is available.

6 Zabbix appliance

Overview Zabbix appliance provides a way to instantly deploy Zabbix server and frontend, instead of setting them up manually or reusing an existing server for Zabbix.

The appliance is based on AlmaLinux 8 (x86_64) and contains a pre-configured Zabbix server running on MySQL and frontend running on Nginx web server.

Attention:

This appliance is designed for evaluating Zabbix. Using it in serious production environments is discouraged.

Appliance images are available for [download](#) in the following formats:

- Installation CD/DVD (.iso)
- VMware (.vmx) - see [notes](#)
- Open virtualization format (.ovf)
- Microsoft Hyper-V (.vhd/.vhdx) - see [notes](#)
- KVM, Parallels, QEMU, USB stick, VirtualBox, Xen (.raw) - see [notes](#)
- KVM, QEMU (.qcow2)

Zabbix installation CD/DVD boot menu:

Quick start Pre-requisites

1. Make sure the host machine has sufficient resources to meet the virtual machine's system requirements:

- *RAM*: 4 GB
 - *Disk space*: at least 8 GB should be allocated for the virtual machine
 - *CPU*: 2 cores minimum
2. If not yet installed, install the virtualization software for booting the appliance image (for example, [VirtualBox](#)).
 3. [Download](#) the appliance in the format supported by your virtualization software.
 4. Check network settings to ensure that DHCP is enabled on the host machine.

Installation

1. Boot the appliance virtual machine from the downloaded image.
2. Configure virtual machine network settings to allow access from a browser on the host machine. This can be achieved by enabling *Bridged mode*.
3. Log in to the virtual machine using default system **credentials**.
4. To retrieve the IP address, run the following command on the virtual machine:

```
ip addr show
```

5. Open a browser on the host machine and point it to the IP address the appliance has received over DHCP.
6. Log in to Zabbix using default **credentials** and start monitoring.

Configuration This section describes frequently required default configuration settings along with available customization options.

Credentials

System

- Username: root
- Password: zabbix

Zabbix frontend

- Username: Admin
- Password: zabbix

After logging in, you can change default password in the **user profile settings** or **create new users** and delete the default one.

Database

Passwords for all database users are randomly generated during the installation process. The following users are defined for the database:

Root:

- Username: root
- Password: the password is stored in the `/root/.my.cnf` file. It is not required to input a password under the root account.

Zabbix server:

- Username: zabbix_srv
- Password: the password is stored in the `/etc/zabbix/zabbix_server.conf`

Zabbix frontend:

- Username: zabbix_web
- Password: the password is stored in the `/etc/zabbix/web/zabbix.conf.php`

To change a database user password, modify it in MySQL and the corresponding configuration file.

Frontend access

Zabbix frontend can be accessed at `http://<virtual machine's IP>`.

By default, access is allowed from anywhere. To limit the access, modify `/etc/nginx/conf.d/zabbix.conf`. After saving the edited file, restart Nginx by logging in via SSH as **root user** and executing:

```
systemctl restart nginx
```

Static IP address

By default, the appliance uses DHCP to obtain the IP address. To set a static IP address:

- Log in as **root user**.
- Run the following commands, replacing values with your custom IP addresses:

```
nmcli connection modify eth0 ipv4.addresses 192.168.1.10/24 # Appliance IP address/CIDR prefix
nmcli connection modify eth0 ipv4.gateway 192.168.1.1 # Gateway IP address
nmcli connection modify eth0 ipv4.dns 8.8.8.8 # DNS server IP address
nmcli connection modify eth0 ipv4.method manual
systemctl restart network
```

Alternatively, you can open the file `/etc/NetworkManager/system-connections/eth0.nmconnection` and add the following lines:

```
[ipv4]
address1=192.168.1.10/24,192.168.1.1
dns=8.8.8.8
method=manual
```

After saving the edited file, run the command `systemctl restart network`.

Firewall configuration

To manage firewall settings, the appliance uses iptables with predefined rules:

- Open SSH port (22 TCP)
- Open Zabbix agent (10050 TCP) and Zabbix trapper (10051 TCP) ports
- Open HTTP (80 TCP) and HTTPS (443 TCP) ports
- Open SNMP trap port (162 UDP)
- Open outgoing connections to NTP port (123 UDP)
- Limit ICMP packets to 5 packets per second
- Drop all other incoming connections

To open additional ports, modify `/etc/sysconfig/iptables` file and reload firewall rules:

```
systemctl reload iptables
```

Repositories

Zabbix appliance uses *zabbix-release* package from the Zabbix [repository](#). Repositories are configured in `/etc/yum.repos.d/*` directory.

Time zone

By default, the appliance uses UTC for the system clock. To change the time zone, copy the appropriate file from `/usr/share/zoneinfo` to `/etc/localtime`, for example:

```
cp /usr/share/zoneinfo/Europe/Riga /etc/localtime
```

Note:

Zabbix **frontend time zone** is set separately and can be changed in the frontend settings. The default time zone for Zabbix frontend is Europe/Riga.

File locations

- Configuration files are located in `/etc/zabbix`
- Zabbix server, proxy, and agent log files are located in `/var/log/zabbix`
- Zabbix frontend is located in `/usr/share/zabbix`
- The home directory for *zabbix* user is `/var/lib/zabbix`

System services

Systemd services are available. To see the list of Zabbix services, run the following command on the virtual machine:

```
systemctl list-units zabbix*
```

Image format-specific notes VMware

The images in *vmdk* format are usable directly in VMware Player, Server, and Workstation products. For use in ESX, ESXi, and vSphere they must be converted using [VMware vCenter Converter](#) (authentication required for download). If you use VMware vCenter Converter, you may encounter issues with the hybrid network adapter. In that case, you can try specifying the E1000 adapter during the conversion process. Alternatively, after the conversion is complete, you can delete the existing adapter and add an E1000 adapter.

HDD/flash image (raw)

To boot the image, run:

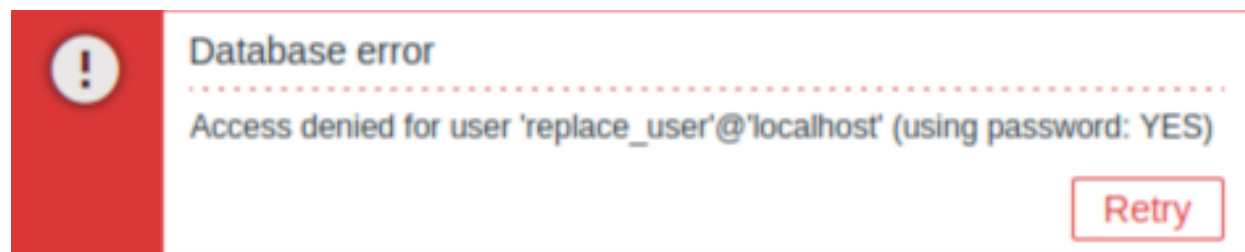

```
dd if=./zabbix_appliance_7.0.0.raw of=/dev/sdc bs=4k conv=fdatasync
```

Replace `/dev/sdc` with your Flash/HDD disk device path.

Hyper-V

If the appliance fails to start up in Hyper-V, try pressing **Ctrl+Alt+F2** to switch a TTY session.

Troubleshooting If you encounter the error message *Access denied for user 'replace_user'@'localhost' (using password: YES)* while trying to log in to the frontend, it may indicate that the installation is still in progress.

If the error persists after waiting a few minutes, or if you observe any other unexpected behavior, it likely means that the installation process has not completed successfully. In this case, we recommend deleting the current appliance and redeploying it by following the same installation instructions. This step typically resolves the issue.

Note that attempting to manually fix a broken installation is not recommended, as it may lead to further complications.

7 Configuration

Please use the sidebar to access content in the Configuration section.

1 Configuring a template

Overview

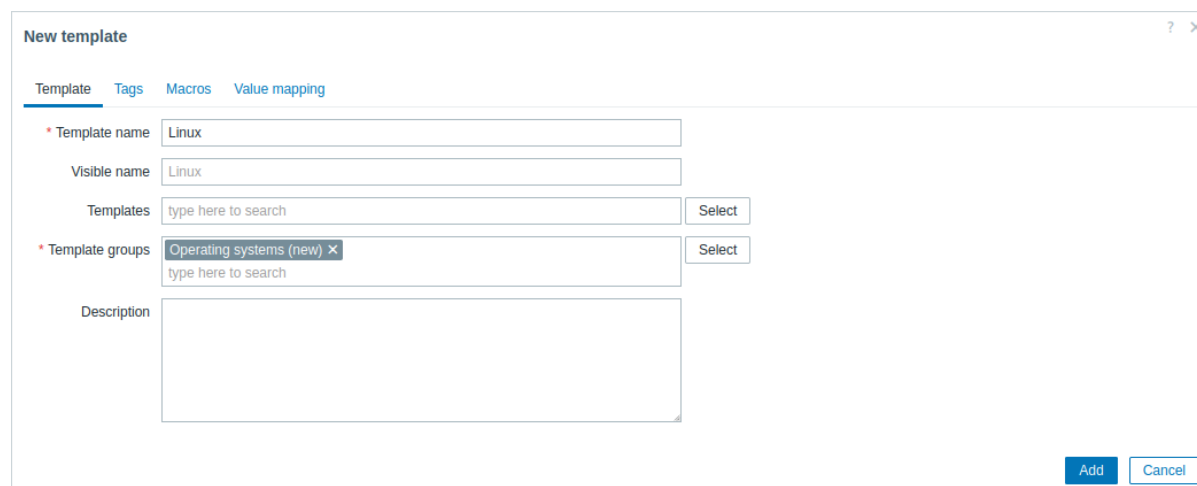

Configuring a template requires that you first create a template by defining its general parameters and then you add entities (items, triggers, graphs, etc.) to it.

Creating a template

To create a template, do the following:

1. Go to *Data collection* → *Templates*.
2. Click on *Create template*.
3. Edit template attributes.

The **Template** tab contains general template attributes.

All mandatory input fields are marked with a red asterisk.

Template attributes:

| Parameter | Description |
|---------------------------|---|
| <i>Template name</i> | Unique template name. Alphanumerics, spaces, dots, dashes, and underscores are allowed. Leading and trailing spaces are not allowed. |
| <i>Visible name</i> | If you set this name, it will be the one visible in lists, maps, etc. |
| <i>Templates</i> | Link one or more templates to this template. All entities (items, triggers, etc.) will be inherited from the linked templates. To link a new template, type its name in the <i>Templates</i> field—this will display a drop-down list of matching templates. Alternatively, click <i>Select</i> to open the <i>Templates</i> pop-up, which initially shows no templates. To populate the list, either type a template group name in the <i>Template group</i> field (and select one from the suggested list) or press the <i>Select</i> button next to the <i>Template group</i> field to open a <i>Template groups</i> pop-up. Once you choose a template group, the <i>Templates</i> pop-up is updated to show the templates belonging to that group. The selected templates will be linked when the configuration is saved or updated. To unlink a template, use one of the two options in the <i>Templates</i> block: <i>Unlink</i> - unlink the template, but preserve its entities (items, triggers, etc.); <i>Unlink and clear</i> - unlink the template and remove all of its entities (items, triggers, etc.). |
| <i>Template groups</i> | Template groups the template belongs to. |
| <i>Description</i> | Template description. |
| <i>Vendor and version</i> | Template vendor and version; displayed only when updating existing templates (out-of-the-box templates provided by Zabbix, imported templates , or templates modified through the Template API) if the template configuration contains such information. Cannot be modified in Zabbix frontend. For out-of-the-box templates, version is displayed as follows: major version of Zabbix, delimiter (" - "), revision number (increased with each new version of the template, and reset with each major version of Zabbix). For example, 7.0-0, 7.0-5, 7.2-0, 7.2-3. |

The **Tags** tab allows you to define template-level **tags**. All problems of hosts linked to this template will be tagged with the values entered here.

[Add](#) [Cancel](#)

For convenience, links to the respective templates, as well as a link to global macro configuration is provided. It is also possible to edit a linked template macro or global macro on the template level, effectively creating a copy of the macro on the template.

The **Value mapping** tab allows to configure human-friendly representation of item data in **value mappings**.

Buttons:

| | |
|----------------------------------|---|
| Add | Add the template. The added template should appear in the list. |
| Update | Update the properties of an existing template. |
| Clone | Create another template based on the properties of the current template. This includes the entities (items, triggers, etc.) both inherited from linked templates and directly attached to the current template, but excludes the current template's vendor and version for the cloned template to be distinguishable from the original. |
| Delete | Delete the template; entities of the template (items, triggers, etc.) remain with the linked hosts. |
| Delete and clear | Delete the template and all its entities from linked hosts. |

Cancel

Cancel the editing of template properties.

Adding items, triggers, graphs

Attention:

Items have to be added to a template first. Triggers and graphs cannot be added without the corresponding item.

There are two ways to add items to the template:

1. To create new items, follow the guidelines for [Creating an item](#).
2. To add existing items to the template:
 - Go to *Data collection* → *Hosts* (or *Templates*).
 - Click on *Items* in the row of the required host/template.
 - Mark the checkboxes of items you want to add to the template.
 - Click on *Copy* below the item list.
 - Select the template (or group of templates) the items should be copied to and click on *Copy*.All the selected items should be copied to the template.

Adding triggers and graphs is done in a similar fashion (from the list of triggers and graphs respectively), again, keeping in mind that they can only be added if the required items are added first.

Adding dashboards

To add dashboards to a template in *Data collection* → *Templates*, do the following:

1. Click on *Dashboards* in the row of the template.
2. Configure a dashboard following the guidelines of [configuring dashboards](#).

Attention:

When configuring widgets on a template dashboard (instead of a global dashboard), the host-related parameters are not available, and some parameters have a different label. This is because template dashboards display data only from the host that the template is linked to. For example, the parameters *Host groups*, *Exclude host groups* and *Hosts* in the *Problems* widget are not available, the parameter *Host groups* in the *Host availability* widget is not available, and the parameter *Show hosts in maintenance* is renamed to *Show data in maintenance*, etc. For more information on the availability of parameters in template dashboard widgets, see specific parameters for each [dashboard widget](#).

Note:

For details on accessing host dashboards that are created from template dashboards, see the [host dashboards](#) section.

Configuring low-level discovery rules

See the [low-level discovery](#) section of the manual.

Adding web scenarios

To add web scenarios to a template in *Data collection* → *Templates*, do the following:

1. Click on *Web* in the row of the template.
2. Configure a web scenario following the usual method of [configuring web scenarios](#).

2 Configuring a template group

Overview

Template groups are used for the logical grouping of templates and assigning user permissions to them.

Each template must have at least one template group assigned. A template may belong to multiple template groups, and each template group may contain multiple templates.

Note that in Zabbix, all permissions are based on groups: **user groups**, **host groups**, and template groups. So, even if a single user needs access to a single template, it is granted by adding the user to a user group that has permission to access the template group containing that template.

Configuration

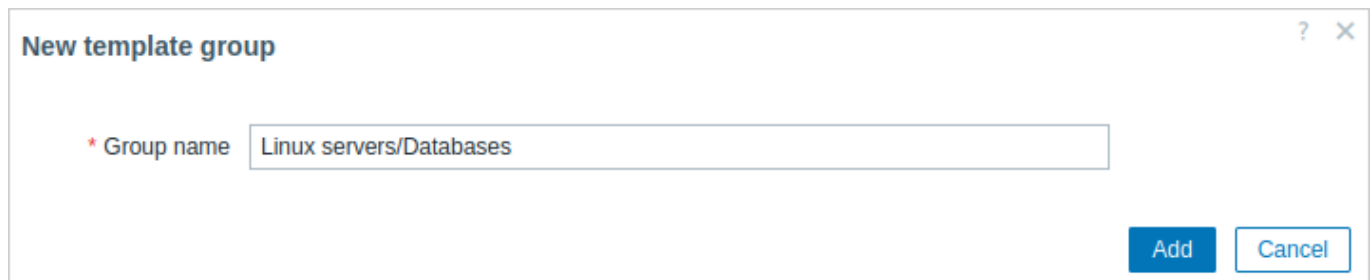

Attention:

Only Super admin users can create template groups.

There are two options of creating a template group in Zabbix frontend.

Option one:

- Go to: *Data collection* → *Template groups*
- Click on *Create template group* in the upper right corner of the screen
- Enter the group name in the form

Option two: when **configuring a template**, enter a non-existing group name in the *Template groups* input field.

Once the template group is created, you can click on the template name in the list under *Data collection* → *Template groups* to edit the group name, clone the group, or delete the group.

Deleting a template group only deletes the logical group, not the templates in the group. It is not possible to delete a template group that is the only group for any existing template.

Creating template subgroups

A template subgroup (or nested template group) is a child of the parent template group that contains it.

A subgroup is created by using the forward slash '/' in the group name input field to denote its relation to the parent group(s). For example:

- inputting `Linux servers/Databases` creates the `Linux servers/Databases` subgroup of the parent group `Linux servers`.
- inputting `Linux servers/Databases/MySQL/Tokyo` creates the respective subgroup within the nested parent groups `Linux servers`, `Linux servers/Databases`, `Linux servers/Databases/MySQL`.

When creating a subgroup, using leading or trailing slashes, or several slashes in a row is not allowed. Escaping of '/' is not supported.

It is not required to create any parent template group(s) before creating a subgroup. You can choose whether to start by creating a subgroup (for example, `Linux servers/Databases`) or any parent template group(s) (in our example, `Linux servers`). If you start by creating a subgroup, parent template group(s) will **not** be created automatically.

Permissions to template groups

- When creating a subgroup to an existing parent template group (for example, creating `Linux servers/Databases` when `Linux servers` already exists), **user group** permissions to the subgroup are inherited from the parent.
- When creating a parent template group to an existing subgroup (for example, creating `Linux servers` when `Linux servers/Databases` already exists), no permissions to the parent are set.

When editing any template group, you can also set an additional option, *Apply permissions to all subgroups*.

Template group

?

×

* Group name

Linux servers/Databases/MySQL

☒ Apply permissions to all subgroups

Update

Clone

Delete

Cancel

Marking this checkbox and clicking on *Update* will apply the same level of permissions to all current and future subgroups of the template group being edited.

So, if any user groups have been given varying **permissions** to the subgroups of the template group being edited, marking the checkbox will grant all current and future subgroups the same user permissions as the group being edited.

Note that this option is not saved in the database and will override existing permissions. Any changes made through this option can be reverted only manually.

3 Linking/unlinking

Overview

Linking is a process whereby templates are applied to hosts, whereas unlinking removes the association with the template from a host.

Linking a template

To link a template to the host, do the following:

1. Go to *Data collection* → *Hosts*.
2. Click on the required host.
3. Start typing the template name in the *Templates* field. A list of matching templates will appear; scroll down to select. Alternatively, you may click on *Select* next to the field and select one or several templates from the list in a popup window.
4. Click on *Add/Update* in the host attributes form.

The host will now have all the entities of the template. This includes items, triggers, graphs, low-level discovery rules, web scenarios, as well as dashboards.

Attention:

Linking multiple templates to the same host will fail if those templates contain items with the same item key. And, as triggers and graphs use items, they cannot be linked to a single host from multiple templates either, if using identical item keys.

When entities (items, triggers, etc.) are added from the template:

- previously existing identical entities on the host are updated as entities of the template, and **any existing host-level customizations to the entity are lost**;
- entities from the template are added;
- any directly linked entities that, prior to template linkage, existed only on the host remain untouched.

In the lists, all entities from the template now are prefixed by the template name, indicating that these belong to the particular template. The template name itself (in gray text) is a link allowing to access the list of those entities on the template level.

Note:

For some items, such as **external checks**, **HTTP agent checks**, **simple checks**, **SSH checks** and **Telnet checks**, a host interface is optional. If, at the time of linking a template, the host does not have an interface defined these items will be added without an interface. If you add a host interface later it will not be assigned automatically to already existing items. To assign the newly added host interface to all template items at once, **unlink** the template from the host and then link it back again. To preserve item history use the option *Unlink*, do not use *Unlink and clear*.

If some entity is not prefixed by the template name, it means that it existed on the host before and was not added by the template.

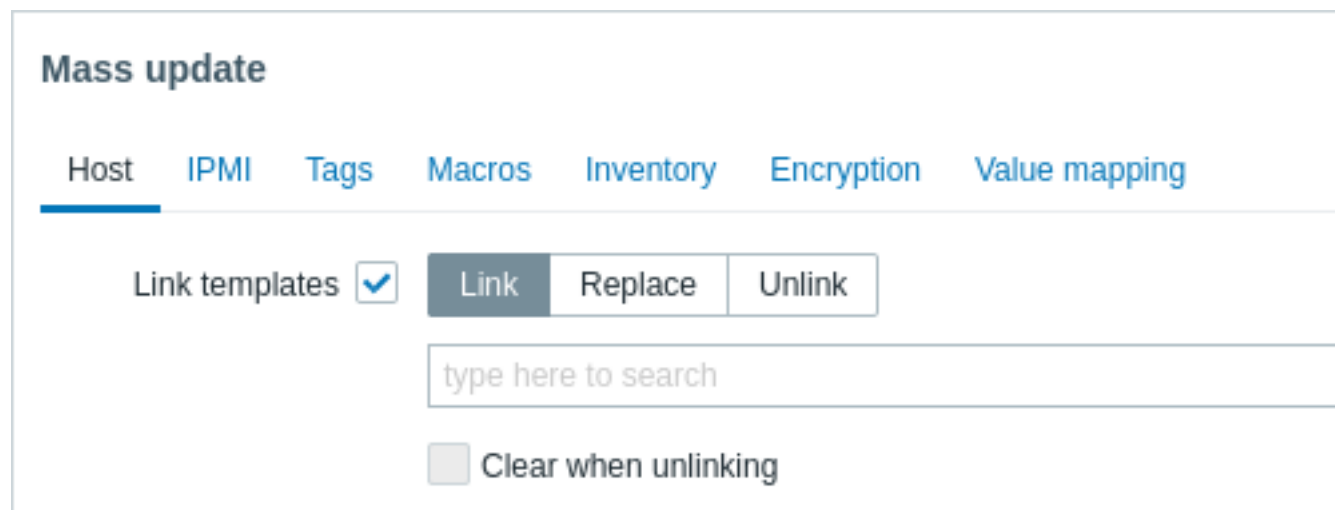

Entity uniqueness criteria

When adding entities (items, triggers, etc.) from a template it is important to know what of those entities already exist on the host and need to be updated and what entities differ. The uniqueness criteria for deciding upon the sameness/difference are:

- for items - the item key;
- for triggers - trigger name and expression;
- for custom graphs - graph name and its items.

Linking templates to several hosts

To update template linkage of many hosts, in *Data collection* → *Hosts* select some hosts by marking their checkboxes, then click on **Mass update** below the list and then select *Link templates*:

To link additional templates, start typing the template name in the auto-complete field until a dropdown appears offering the matching templates. Just scroll down to select the template to link.

The *Replace* option will allow to link a new template while unlinking any template that was linked to the hosts before. The *Unlink* option will allow to specify which templates to unlink. The *Clear when unlinking* option will allow to not only unlink any previously linked templates, but also remove all entities inherited from them (items, triggers, etc.).

Note:

Zabbix offers a sizable set of predefined templates. You can use these for reference, but beware of using them unchanged in production as they may contain too many items and poll for data too often. If you feel like using them, finetune them to fit your real needs.

Editing linked entities

If you try to edit an item or a trigger that was linked from the template, you may realize that many key options are disabled for editing. This makes sense as the idea of templates is that things are edited in a one-touch manner on the template level. However, you still can, for example, enable/disable an item on individual hosts and set the update interval, history length and some other parameters.

If you want to edit the entity fully, you have to edit it on the template level (template level shortcut is displayed in the form name), keeping in mind that these changes will affect all hosts that have this template linked to them.

Attention:

Any customizations to the entities implemented on a template-level will override the previous customizations of the entities on a host-level.

Unlinking a template

To unlink a template from a host, do the following:

1. Go to *Data collection* → *Hosts*.
2. Click on the required host and find the *Templates* field.
3. Click on *Unlink* or *Unlink and clear* next to the template to unlink the template.
4. Click on *Update* in the host attributes form.

Choosing the *Unlink* option will simply remove association with the template, while leaving all its entities with the host. This includes items, triggers, graphs, low-level discovery rules, and web scenarios, but excludes dashboards. Note that value maps and tags inherited from linked templates will also be removed.

Choosing the *Unlink and clear* option will remove both the association with the template and all its entities (items, triggers, etc.).

4 Nesting

Overview

Nesting is a way of one template encompassing one or more other templates.

As it makes sense to separate out entities on individual templates for various services, applications, etc., you may end up with quite a few templates all of which may need to be linked to quite a few hosts. To simplify the picture, it is possible to link some templates together in a single template.

The benefit of nesting is that you have to link only one template to the host, and the host will automatically inherit all entities from the templates that are linked to the one template. For example, if we link *T1* and *T2* to *T3*, we supplement *T3* with all entities from *T1* and *T2*, but not vice versa. If we link *T1* to *T2* and *T3*, we supplement *T2* and *T3* with entities from *T1*.

Configuring nested templates

To link templates, you need to take an existing template (or create a new one), and then:

1. Open the **template configuration form**.
2. Find the *Templates* field.
3. Click on *Select* to open the *Templates* pop-up window.
4. In the pop-up window, choose the required templates, and then click on *Select* to add the templates to the list.
5. Click on *Add or Update* in the template configuration form.

Thus, all entities of the configured template, as well as all entities of linked templates will now appear in the template configuration. This includes items, triggers, graphs, low-level discovery rules, and web scenarios, but excludes dashboards. However, linked template dashboards will, nevertheless, be inherited by hosts.

To unlink any of the linked templates, click on *Unlink* or *Unlink and clear* in the template configuration form, and then click on *Update*.

The *Unlink* option will simply remove the association with the linked template, while not removing any of its entities (items, triggers, etc.).

The *Unlink and clear* option will remove both the association with the linked template, as well as all its entities (items, triggers, etc.).

5 Mass update

Overview

Sometimes you may want to change some attribute for a number of templates at once. Instead of opening each individual template for editing, you may use the mass update function for that.

Using mass update

To mass-update some templates, do the following:

1. Mark the checkboxes before the templates you want to update in the **template list**.
2. Click on *Mass update* below the list.
3. Navigate to the tab with required attributes (*Template*, *Tags*, *Macros* or *Value mapping*).
4. Mark the checkboxes of any attribute to update and enter a new value for them.

The **Template** tab contains general template mass update options.

The following options are available when selecting the respective button for the *Link templates* update:

- *Link* - specify which additional templates to link;
- *Replace* - specify which templates to link while at the same time unlinking any previously linked templates;
- *Unlink* - specify which templates to unlink.

To specify the templates to link/unlink, start typing the template name in the auto-complete field until a dropdown appears offering the matching templates. Just scroll down to select the required templates.

The *Clear when unlinking* option will allow to unlink any previously linked templates, as well as to remove all elements inherited from them (items, triggers, graphs, etc.).

The following options are available when selecting the respective button for the *Template groups* update:

- *Add* - allows to specify additional template groups from the existing ones or enter completely new template groups for the templates;
- *Replace* - will remove the template from any existing template groups and replace them with the one(s) specified in this field (existing or new template groups);
- *Remove* - will remove specific template groups from templates.

These fields are auto-complete - starting to type in them offers a dropdown of matching template groups. If the template group is new, it also appears in the dropdown and it is indicated by *(new)* after the string. Just scroll down to select.

The **Tags** tab allows you to mass update template-level tags.

User macros, {INVENTORY.*} macros, {HOST.HOST}, {HOST.NAME}, {HOST.CONN}, {HOST.DNS}, {HOST.IP}, {HOST.PORT} and {HOST.ID} macros are supported in tags. Note that tags with the same name, but different values are not considered 'duplicates'

145

and can be added to the same template.

The **Macros** tab allows you to mass update template-level macros.

The screenshot shows the 'Mass update' dialog box with the 'Macros' tab selected. At the top, there are four tabs: 'Template', 'Tags', 'Macros' (active), and 'Value mapping'. Below the tabs, there is a section for 'Macros' with a checked checkbox and four buttons: 'Add', 'Update', 'Remove', and 'Remove all'. Below these buttons is a table with three columns: 'Macro', 'Value', and 'Description'. The 'Macro' column contains the text '{ \$MACRO }', the 'Value' column contains 'value', and the 'Description' column contains 'description'. There is a 'Remove' button next to the 'Description' column. Below the table, there is an 'Add' button and a checkbox labeled 'Update existing'. At the bottom right, there are 'Update' and 'Cancel' buttons.

The following options are available when selecting the respective button for macros update:

- **Add** - allows to specify additional user macros for the templates. If *Update existing* checkbox is checked, value, type and description for the specified macro name will be updated. If unchecked, if a macro with that name already exist on the template(s), it will not be updated.
- **Update** - will replace values, types and descriptions of macros specified in this list. If *Add missing* checkbox is checked, macro that didn't previously exist on a template will be added as new macro. If unchecked, only macros that already exist on a template will be updated.
- **Remove** - will remove specified macros from templates. If *Except selected* box is checked, all macros except specified in the list will be removed. If unchecked, only macros specified in the list will be removed.
- **Remove all** - will remove all user macros from templates. If *I confirm to remove all macros* checkbox is not checked, a new popup window will open asking to confirm removal of all macros.

The **Value mapping** tab allows you to mass update **value mappings**.

The screenshot shows the 'Mass update' dialog box with the 'Value mapping' tab selected. At the top, there are four tabs: 'Template', 'Tags', 'Macros', and 'Value mapping' (active). Below the tabs, there is a section for 'Value mapping' with a checked checkbox and five buttons: 'Add', 'Update', 'Rename', 'Remove', and 'Remove all'. Below these buttons is a table with three columns: 'Name', 'Value', and 'Action'. The 'Name' column contains the text 'Add', 'Add from template', and 'Add from host'. The 'Value' column is empty. The 'Action' column is empty. Below the table, there is a checkbox labeled 'Update existing'. At the bottom right, there are 'Update' and 'Cancel' buttons.

Buttons with the following options are available for value map update:

- **Add** - add value maps to the templates. If you mark *Update existing*, all properties of the value map with this name will be updated. Otherwise, if a value map with that name already exists, it will not be updated.
- **Update** - update existing value maps. If you mark *Add missing*, a value map that didn't previously exist on a template will be added as a new value map. Otherwise only the value maps that already exist on a template will be updated.
- **Rename** - give new name to an existing value map.
- **Remove** - remove the specified value maps from the templates. If you mark *Except selected*, all value maps will be removed **except** the ones that are specified.
- **Remove all** - remove all value maps from the templates. If the *I confirm to remove all value maps* checkbox is not marked, a new popup window will open asking to confirm the removal.

Add from template and *Add from host* options are available for value mapping add/update operations. They allow to select value mappings from a template or a host respectively.

When done with all required changes, click on *Update*. The attributes will be updated accordingly for all the selected templates.

1 Hosts and host groups

What is a "host"?

In Zabbix, a "host" refers to any physical or virtual device, application, service, or any other logically-related collection of monitored parameters.

Creating hosts is one of the first monitoring tasks in Zabbix. For example, if you want to monitor some parameters on a server "x", you must first create a host called, say, "Server X" and then you can look to add monitoring items to it.

Hosts are organized into host groups.

Proceed to [creating and configuring a host](#).

1 Configuring a host

Overview

To configure a host in Zabbix frontend, do the following:

- Go to: *Data collection > Hosts* or *Monitoring > Hosts*
- Click on *Create host* to the right (or on the host name to edit an existing host)
- Enter parameters of the host in the form

You can also use the *Clone* button in the configuration form of an existing host to create a new host. This host will have all of the properties of the existing host, including linked templates, entities (items, triggers, etc.) from those templates, as well as the entities directly attached to the existing host.

Note that when a host is cloned, it will retain all template entities as they are originally on the template. Any changes to those entities made on the existing host level (such as changed item interval, modified regular expression or added prototypes to the low-level discovery rule) will not be cloned to the new host; instead they will be as on the template.

Configuration

The **Host** tab contains general host attributes:

☒

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|---------------------|--|
| <i>Host name</i> | Enter a unique host name. Alphanumerics, spaces, dots, dashes and underscores are allowed. However, leading and trailing spaces are disallowed. <i>Note:</i> With Zabbix agent running on the host you are configuring, the agent configuration file parameter <i>Hostname</i> must have the same value as the host name entered here. The name in the parameter is needed in the processing of active checks . |
| <i>Visible name</i> | Enter a unique visible name for the host. If you set this name, it will be the one visible in lists, maps, etc instead of the technical host name. This attribute has UTF-8 support. |
| <i>Templates</i> | Link templates to the host. All entities (items, triggers, <i>etc.</i>) will be inherited from the template. To link a new template, start typing the template name in the text input field. A list of matching templates will appear; scroll down to select. Alternatively, you may click on <i>Select</i> next to the field and select templates from the list in a popup window. All selected templates will be linked to the host when the host configuration form is saved or updated. To unlink a template, use one of the two options in the <i>Linked templates</i> block: <i>Unlink</i> - unlink the template, but preserve its entities (items, triggers, <i>etc.</i>); <i>Unlink and clear</i> - unlink the template and remove all its entities (items, triggers, <i>etc.</i>). Listed template names are clickable links leading to the template configuration form. |

| Parameter | Description |
|---------------------|--|
| <i>Host groups</i> | Select host groups the host belongs to. A host must belong to at least one host group. A new group can be created and linked to the host by adding a non-existing group name. |
| <i>Interfaces</i> | Several host interface types are supported for a host: <i>Agent</i> , <i>SNMP</i> , <i>JMX</i> and <i>IPMI</i> . No interfaces are defined by default. To add a new interface, click on <i>Add</i> in the <i>Interfaces</i> block, select the interface type and enter <i>IP/DNS</i> , <i>Connect to</i> and <i>Port</i> info. <i>Note:</i> Interfaces that are used in any items cannot be removed and link <i>Remove</i> is grayed out for them. The "IP" or "DNS" from an SNMP interface is also used for SNMP traps . During matching, only the selected "IP" or "DNS" in the host interface is used. See Configuring SNMP monitoring for additional details on configuring an SNMP interface (v1, v2 and v3). |
| <i>IP address</i> | Host IP address (optional). |
| <i>DNS name</i> | Host DNS name (optional). |
| <i>Connect to</i> | Clicking the respective button will tell Zabbix server what to use to retrieve data from agents: IP - Connect to the host IP address (recommended) DNS - Connect to the host DNS name |
| <i>Port</i> | TCP/UDP port number. Default values are: 10050 for Zabbix agent, 161 for SNMP agent, 12345 for JMX and 623 for IPMI. |
| <i>Default</i> | Check the radio button to set the default interface. |
| <i>Description</i> | Enter the host description. |
| <i>Monitored by</i> | Select if the host is monitored by: Server - host is monitored by Zabbix server; Proxy - host is monitored by standalone proxy; Proxy group - host is monitored by proxy group. |
| <i>Proxy</i> | The assigned proxy name is displayed (only if Zabbix server has assigned one from the selected proxy group). |
| <i>Enabled</i> | This field is displayed only if the host is monitored by a proxy group. When the checkbox is checked, the host is enabled - ready for monitoring. When the checkbox is unchecked, the host is disabled - not monitored: For passive data requests initiated by Zabbix server/proxy (for example, Zabbix agent , SNMP agent , simple checks), monitoring is disabled after configuration synchronization. Triggers and actions linked to the host are also disabled only after the configuration is reloaded. For Zabbix agent active checks , monitoring stops within the time frame (approx. 5 seconds) that Zabbix agent receives information about the host having been disabled. During this brief interval, the host will continue to locally collect data for the active checks and try sending it to the server/proxy; however, since the host is marked as <i>Disabled</i> , the server/proxy will reject the data. |

The **IPMI** tab contains IPMI management attributes.

| Parameter | Description |
|---------------------------------|--|
| <i>Authentication algorithm</i> | Select the authentication algorithm. |
| <i>Privilege level</i> | Select the privilege level. |
| <i>Username</i> | User name for authentication. User macros may be used. |
| <i>Password</i> | Password for authentication. User macros may be used. |

The **Tags** tab allows you to define host-level **tags**. All problems of this host will be tagged with the values entered here.

| {\$HOST_MACRO} | 1 | T ▼ | Remove |

For convenience, links to respective templates and global macro configuration are provided. It is also possible to edit a template/global macro on the host level, effectively creating a copy of the macro on the host.

The **Inventory** tab allows you to manually enter **inventory** information for the host. You can also select to enable *Automatic* inventory population, or disable inventory population for this host.

Host IPMI Tags 1 Macros 2 **Inventory ●** Encryption Value mapping 1

Disabled Manual **Automatic**

Type Zabbix server

Type (Full details)

If inventory is enabled (manual or automatic), a green dot is displayed with the tab name.

Encryption

The **Encryption** tab allows you to require **encrypted** connections with the host.

| Parameter | Description |
|------------------------------|--|
| <i>Connections to host</i> | How Zabbix server or proxy connects to Zabbix agent on a host: no encryption (default), using PSK (pre-shared key) or certificate. |
| <i>Connections from host</i> | Select what type of connections are allowed from the host (i.e. from Zabbix agent and Zabbix sender). Several connection types can be selected at the same time (useful for testing and switching to other connection type). Default is "No encryption". |
| <i>Issuer</i> | Allowed issuer of certificate. Certificate is first validated with CA (certificate authority). If it is valid, signed by the CA, then the <i>Issuer</i> field can be used to further restrict allowed CA. This field is intended to be used if your Zabbix installation uses certificates from multiple CAs. If this field is empty then any CA is accepted. |
| <i>Subject</i> | Allowed subject of certificate. Certificate is first validated with CA. If it is valid, signed by the CA, then the <i>Subject</i> field can be used to allow only one value of <i>Subject</i> string. If this field is empty then any valid certificate signed by the configured CA is accepted. |
| <i>PSK identity</i> | Pre-shared key identity string. Do not put sensitive information in the PSK identity, it is transmitted unencrypted over the network to inform a receiver which PSK to use. |
| <i>PSK</i> | Pre-shared key (hex-string). Maximum length: 512 hex-digits (256-byte PSK) if Zabbix uses GnuTLS or OpenSSL library, 64 hex-digits (32-byte PSK) if Zabbix uses mbed TLS (PolarSSL) library. Example: 1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952 |

Value mapping

The **Value mapping** tab allows to configure human-friendly representation of item data in **value mappings**.

2 Configuring a host group

Overview

Host groups are used for the logical grouping of hosts and assigning user permissions to them.

Each host must have at least one host group assigned. A host may belong to multiple host groups, and each host group may contain multiple hosts.

Note that in Zabbix, all permissions are based on groups: **user groups**, host groups, and **template groups**. So, even if a single user needs access to a single host, it is granted by adding the user to a user group that has permission to access the host group containing that host.

Configuration

Attention:

Only Super admin users can create host groups.

There are two options of creating a host group in Zabbix frontend.

Option one:

- Go to: *Data collection* → *Host groups*
- Click on *Create host group* in the upper right corner of the screen
- Enter the group name in the form

Option two: when **configuring a host**, enter a non-existing group name in the *Host groups* input field.

Once the host group is created, you can click on the group name in the list under *Data collection* → *Host groups* to edit the group name, clone the group, or delete the group.

Deleting a host group only deletes the logical group, not the hosts in the group. It is not possible to delete a host group that is the only group for any existing host.

Creating host subgroups

A host subgroup (or nested host group) is a child of the parent host group that contains it.

A subgroup is created by using the forward slash '/' in the group name input field to denote its relation to the parent group(s). For example:

- inputting Europe/Latvia creates the Europe/Latvia subgroup of the parent group Europe.
- inputting Europe/Latvia/Riga/Zabbix servers creates the respective subgroup within the nested parent groups Europe, Europe/Latvia, Europe/Latvia/Riga.

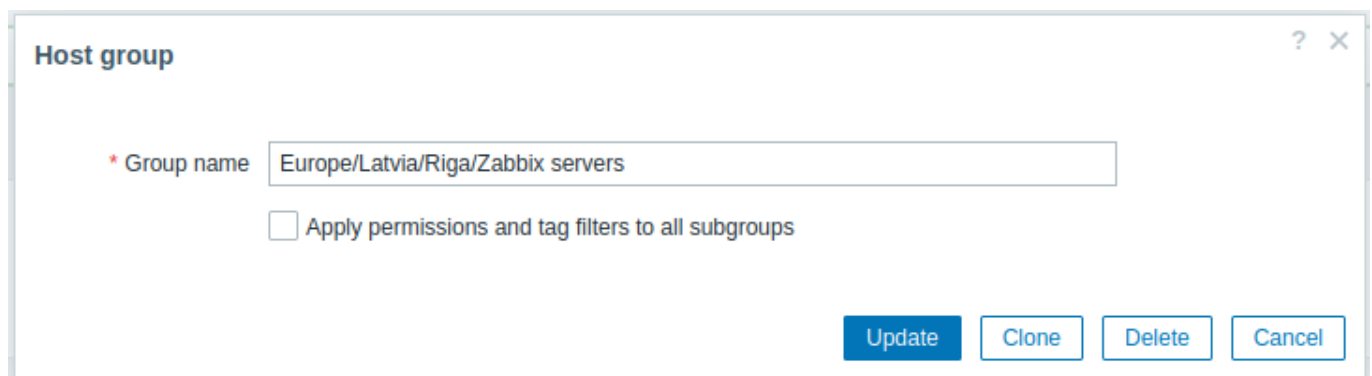

When creating a subgroup, using leading or trailing slashes, or several slashes in a row is not allowed. Escaping of '/' is not supported.

It is not required to create any parent host group(s) before creating a subgroup. You can choose whether to start by creating a subgroup (for example, Europe/Latvia) or any parent host group(s) (in our example, Europe). If you start by creating a subgroup, parent host group(s) will **not** be created automatically.

Permissions to host groups

- When creating a subgroup to an existing parent host group (for example, creating Europe/Latvia when Europe already exists), **user group** permissions to the subgroup are inherited from the parent.
- When creating a parent host group to an existing subgroup (for example, creating Europe when Europe/Latvia already exists), no permissions to the parent are set.

When editing any host group, you can also set an additional option, *Apply permissions and tag filters to all subgroups*.

Marking this checkbox and clicking on *Update* will apply the same level of permissions and tag filters to all current and future subgroups of the host group being edited.

So, if any user groups have been given varying **permissions** to the subgroups of the host group being edited, marking the checkbox will grant all current and future subgroups the same user permissions and tag-based permissions as the group being edited.

Note that this option is not saved in the database and will override existing permissions. Any changes made through this option can be reverted only manually.

3 Inventory

Overview

You can keep the inventory of networked devices in Zabbix.

There is a special *Inventory* menu in the Zabbix frontend. However, you will not see any data there initially and it is not where you enter data. Building inventory data is done manually when configuring a host or automatically by using some automatic population options.

Building inventory

Manual mode

When **configuring a host**, in the *Inventory* tab you can enter such **details** as the type of device, serial number, location, responsible person, URLs, etc. - data that will populate inventory information.

If a URL is included in host inventory information and it starts with 'http' or 'https', it will result in a clickable link in the *Inventory* section.

Automatic mode

Host inventory can also be populated automatically. For that to work, when configuring a host the inventory mode in the *Inventory* tab must be set to *Automatic*.

Then you can **configure host items** to populate any host inventory field with their value, indicating the destination field with the respective attribute (called *Item will populate host inventory field*) in item configuration.

Items that are especially useful for automated inventory data collection:

- system.hw.chassis[full|type|vendor|model|serial] - default is [full], root permissions needed
- system.hw.cpu[all|cpunum,full|maxfreq|vendor|model|curfreq] - default is [all,full]
- system.hw.devices[pci|usb] - default is [pci]
- system.hw.macaddr[interface,short|full] - default is [all,full], interface is regexp
- system.sw.arch
- system.sw.os[name|short|full] - default is [name]
- system.sw.packages[regexp,manager,short|full] - default is [all,all,full]

Inventory mode selection

Inventory mode can be selected in the host configuration form.

Inventory mode by default for new hosts is selected based on the *Default host inventory mode* setting in *Administration* → *General* → *Other*.

For hosts added by network discovery or autoregistration actions, it is possible to define a *Set host inventory mode* operation selecting manual or automatic mode. This operation overrides the *Default host inventory mode* setting.

Inventory overview

The details of all existing inventory data are available in the *Inventory* menu.

In *Inventory* → *Overview* you can get a host count by various fields of the inventory.

In *Inventory* → *Hosts* you can see all hosts that have inventory information. Clicking on the host name will reveal the inventory details in a form.

≡ Host inventory

Overview Details

[Cancel](#)

The **Overview** tab shows:

| Parameter | Description |
|--|---|
| <i>Host name</i> | Name of the host. Clicking on the name opens a menu with the scripts defined for the host. Host name is displayed with an orange icon, if the host is in maintenance. |
| <i>Visible name</i> | Visible name of the host (if defined). |
| <i>Host (Agent, SNMP, JMX, IPMI) interfaces</i> | This block provides details of the interfaces configured for the host. |
| <i>OS</i> | Operating system inventory field of the host (if defined). |

| Parameter | Description |
|----------------------|---|
| <i>Hardware</i> | Host hardware inventory field (if defined). |
| <i>Software</i> | Host software inventory field (if defined). |
| <i>Description</i> | Host description. |
| <i>Monitoring</i> | Links to monitoring sections with data for this host: <i>Web, Latest data, Problems, Graphs, Dashboards</i> . |
| <i>Configuration</i> | Links to configuration sections for this host: <i>Host, Items, Triggers, Graphs, Discovery, Web</i> . The amount of configured entities is listed after each link. |

The **Details** tab shows all inventory fields that are populated (are not empty).

Inventory macros

There are host inventory macros {INVENTORY.*} available for use in notifications, for example:

"Server in {INVENTORY.LOCATION1} has a problem, responsible person is {INVENTORY.CONTACT1}, phone number {INVENTORY.POC.PRIMARY.PHONE.A1}."

For more details, see the [Supported macros](#) page.

4 Mass update

Overview

Sometimes you may want to change some attribute for a number of hosts at once. Instead of opening each individual host for editing, you may use the mass update function for that.

Using mass update

To mass-update some hosts, do the following:

- Mark the checkboxes before the hosts you want to update in the [host list](#)
- Click on *Mass update* below the list
- Navigate to the tab with required attributes (*Host, IPMI, Tags, Macros, Inventory, Encryption or Value mapping*)
- Mark the checkboxes of any attribute to update and enter a new value for them

The following options are available when selecting the respective button for **template** linkage update:

- *Link* - specify which additional templates to link
- *Replace* - specify which templates to link while unlinking any template that was linked to the hosts before
- *Unlink* - specify which templates to unlink

To specify the templates to link/unlink start typing the template name in the auto-complete field until a dropdown appears offering the matching templates. Just scroll down to select the required template.

The *Clear when unlinking* option will allow to not only unlink any previously linked templates, but also remove all elements inherited from them (items, triggers, etc.).

The following options are available when selecting the respective button for **host group** update:

- *Add* - allows to specify additional host groups from the existing ones or enter completely new host groups for the hosts
- *Replace* - will remove the host from any existing host groups and replace them with the one(s) specified in this field (existing or new host groups)
- *Remove* - will remove specific host groups from hosts

These fields are auto-complete - starting to type in them offers a dropdown of matching host groups. If the host group is new, it also appears in the dropdown and it is indicated by *(new)* after the string. Just scroll down to select.

☐ Update existing

The following options are available when selecting the respective button for macros update:

- **Add** - allows to specify additional user macros for the hosts. If *Update existing* checkbox is checked, value, type and description for the specified macro name will be updated. If unchecked, if a macro with that name already exist on the host(s), it will not be updated.
- **Update** - will replace values, types and descriptions of macros specified in this list. If *Add missing* checkbox is checked, macro that didn't previously exist on a host will be added as new macro. If unchecked, only macros that already exist on a host will be updated.
- **Remove** - will remove specified macros from hosts. If *Except selected* box is checked, all macros except specified in the list will be removed. If unchecked, only macros specified in the list will be removed.
- **Remove all** - will remove all user macros from hosts. If *I confirm to remove all macros* checkbox is not checked, a new popup window will open asking to confirm removal of all macros.

☐ Update existing

Buttons with the following options are available for value map update:

- **Add** - add value maps to the hosts. If you mark *Update existing*, all properties of the value map with this name will be updated. Otherwise, if a value map with that name already exists, it will not be updated.
- **Update** - update existing value maps. If you mark *Add missing*, a value map that didn't previously exist on a host will be added as a new value map. Otherwise only the value maps that already exist on a host will be updated.
- **Rename** - give new name to an existing value map
- **Remove** - remove the specified value maps from the hosts. If you mark *Except selected*, all value maps will be removed **except** the ones that are specified.
- **Remove all** - remove all value maps from the hosts. If the *I confirm to remove all value maps* checkbox is not marked, a new popup window will open asking to confirm the removal.

When done with all required changes, click on *Update*. The attributes will be updated accordingly for all the selected hosts.

2 Items

Overview

An item is an individual metric.

Items are used for collecting data. Once you have configured a host, you must add items to get actual data. One way of quickly adding many items is to attach one of the predefined templates to a host. However, for optimized system performance, you may need to fine-tune the templates to have as many items and as frequent monitoring as necessary.

To specify what sort of data to collect from a host, use the **item key**. For example, an item with the key name **system.cpu.load** will collect processor load data, while an item with the key name **net.if.in** will collect incoming traffic information.

Additional parameters can be specified in square brackets after the key name. For example, `system.cpu.load[avg5]` will return the processor load average for the last 5 minutes, while `net.if.in[eth0]` will show incoming traffic in the interface "eth0".

Note:
See individual sections of **item types** for all supported item types and item keys.

Proceed to **creating and configuring an item**.

1 Creating an item

Overview

To create an item in Zabbix frontend, do the following:

- Go to: *Data collection* → *Hosts*
- Click on *Items* in the row of the host
- Click on *Create item* in the upper right corner of the screen
- Enter parameters of the item in the form

You can also create an item by opening an existing one, pressing the *Clone* button and then saving under a different name.

Configuration

The **Item** tab contains general item attributes.

| Parameter | Description |
|-----------|---|
| Name | Item name. User macros are supported. |
| Type | Item type. See individual item type sections. |

| Parameter | Description |
|---------------------|---|
| Key | <p>Item key (up to 2048 characters).</p> <p>The supported item keys can be found in individual item type sections.</p> <p>The key must be unique within a single host.</p> <p>If key type is 'Zabbix agent', 'Zabbix agent (active)' or 'Simple check', the key value must be supported by Zabbix agent or Zabbix server.</p> <p>See also: the correct key format.</p> |
| Type of information | <p>Type of data as stored in the database after performing conversions, if any.</p> <p>Numeric (unsigned) - 64-bit unsigned integer.</p> <p>Note that a floating point value, if received for an integer item, will be trimmed from its decimal part.</p> <p>Numeric (float) - 64-bit floating point number.</p> <p>This type will allow precision of approximately 15 digits and range from approximately -1.79E+308 to 1.79E+308 (with exception of PostgreSQL 11 and earlier versions).</p> <p>Receiving values in scientific notation is also supported. E.g. 1.23E+7, 1e308, 1.1E-4.</p> <p>Character - short text data.</p> <p>Log - long text data with optional log related properties (timestamp, source, severity, logeventid).</p> <p>Text - long text data. See also text data limits.</p> <p>Binary - binary number (supported for dependent items only). A binary number will be resolved to a static "binary value" string in <i>Latest data</i>; {ITEM.VALUE}, {ITEM.LASTVALUE} and expression macros will resolve to UNKNOWN.</p> <p>For item keys that return data only in one specific format, matching type of information is selected automatically.</p> |
| Host interface | Select the host interface. This field is available when editing an item on the host level. |
| Units | <p>If a unit symbol is set, Zabbix applies postprocessing to the received item value and displays it with the specified unit postfix.</p> <p>Supported unit symbols with special formatting (and examples of received item value → displayed value):</p> <p>B - bytes (1024 → 1 KB)</p> <p>Bps - bytes per second (1024 → 1 KBps)</p> <p>s - seconds, displayed using up to three largest non-zero time units (881764 → 10d 4h 56m)</p> <p>uptime - elapsed time in hh:mm:ss or N days, hh:mm:ss (881764 → 10 days, 04:56:04)</p> <p>unixtime - Unix timestamp, formatted as yyyy.mm.dd hh:mm:ss (881764 → 1970-01-11 04:56:04 AM); for correct formatting, the received item value must be <i>Numeric (unsigned)</i>.</p> <p>For other units (such as Hz, W, etc.), if the received value exceeds 1000, it is divided by 1000 and displayed with a corresponding prefix (5000 → 5 KHz, 881764 → 881.76 KW).</p> <p>If the unit symbol is prefixed with !, unit conversion and prefixing are disabled (1024 !B → 1024 B, 61 !s → 61 s).</p> <p>For more examples and details on unit symbols and unit conversion, see Item value suffixes.</p> |
| Update interval | <p>Retrieve a new value for this item every N seconds. Maximum allowed update interval is 86400 seconds (1 day).</p> <p>Time suffixes are supported, e.g., 30s, 1m, 2h, 1d.</p> <p>User macros are supported.</p> <p>A single macro has to fill the whole field. Multiple macros in a field or macros mixed with text are not supported.</p> <p>Note: The update interval can only be set to '0' if custom intervals exist with a non-zero value. If set to '0', and a custom interval (flexible or scheduled) exists with a non-zero value, the item will be polled during the custom interval duration.</p> <p>Note that the first item poll after the item became active or after update interval change might occur earlier than the configured value.</p> <p>New items will be checked within 60 seconds of their creation, unless they have Scheduling or Flexible update interval and the <i>Update interval</i> is set to 0.</p> <p>An existing passive item can be polled for value immediately by pushing the <i>Execute now</i> button.</p> |
| Custom intervals | <p>You can create custom rules for checking the item:</p> <p>Flexible - create an exception to the <i>Update interval</i> (interval with different frequency).</p> <p>Scheduling - create a custom polling schedule.</p> <p>For detailed information see Custom intervals.</p> <p>Time suffixes are supported in the <i>Interval</i> field, e.g., 30s, 1m, 2h, 1d.</p> <p>User macros are supported.</p> <p>A single macro has to fill the whole field. Multiple macros in a field or macros mixed with text are not supported.</p> |

| Parameter | Description |
|---------------------------------------|--|
| <i>Timeout</i> | <p>Set the item check timeout (available for supported item types). Select the timeout option:</p> <p>Global - proxy/global timeout is used (displayed in the grayed out <i>Timeout</i> field).</p> <p>Override - custom timeout is used (set in the <i>Timeout</i> field; allowed range: 1 - 600s). Time suffixes, e.g. 30s, 1m, and user macros are supported.</p> <p>Clicking the <i>Timeouts</i> link allows you to configure proxy timeouts or global timeouts (if a proxy is not used). Note that the <i>Timeouts</i> link is visible only to users of <i>Super admin</i> type with permissions to <i>Administration</i> → General or <i>Administration</i> → Proxies frontend sections.</p> |
| <i>History</i> | <p>Select either:</p> <p>Do not store - item history is not stored. Useful for master items if only dependent items need to keep history.</p> <p>This setting cannot be overridden by global housekeeper settings.</p> <p>Store up to - specify the duration of keeping detailed history in the database (1 hour to 25 years). Older data will be removed by the housekeeper. Stored in seconds.</p> <p>Time suffixes are supported, e.g., 2h, 1d. User macros are supported.</p> <p>The <i>Store up to</i> value can be overridden globally in <i>Administration</i> → Housekeeping.</p> <p>If a global overriding setting exists, an orange  info icon is displayed. If you position your mouse on it, a warning message is displayed, e.g., <i>Overridden by global housekeeper settings (1d)</i>.</p> <p>It is recommended to keep the recorded values for the smallest possible time to reduce the size of value history in the database. Instead of storing a long history of values, you can store longer data of trends.</p> <p>See also History and trends.</p> |
| <i>Trends</i> | <p>Select either:</p> <p>Do not store - trends are not stored.</p> <p>This setting cannot be overridden by global housekeeper settings.</p> <p>Store up to - specify the duration of keeping aggregated (hourly min, max, avg, count) history in the database (1 day to 25 years). Older data will be removed by the housekeeper. Stored in seconds.</p> <p>Time suffixes are supported, e.g., 24h, 1d. User macros are supported.</p> <p>The <i>Store up to</i> value can be overridden globally in <i>Administration</i> → Housekeeping.</p> <p>If a global overriding setting exists, an orange  info icon is displayed. If you position your mouse on it, a warning message is displayed, e.g., <i>Overridden by global housekeeper settings (7d)</i>.</p> <p><i>Note:</i> Keeping trends is not available for non-numeric data - character, log and text.</p> <p>See also History and trends.</p> |
| <i>Value mapping</i> | <p>Apply value mapping to this item. Value mapping does not change received values, it is for displaying data only.</p> <p>It works with <i>Numeric(unsigned)</i>, <i>Numeric(float)</i> and <i>Character</i> items.</p> <p>For example, "Windows service states".</p> |
| <i>Log time format</i> | <p>Available for items of type Log only. Supported placeholders:</p> <p>y: Year (1970-2038).</p> <p>M: Month (01-12).</p> <p>d: Day (01-31).</p> <p>h: Hour (00-23).</p> <p>m: Minute (00-59).</p> <p>s: Second (00-59).</p> <p>If left blank, the timestamp will be set to 0 in Unix time, representing January 1, 1970.</p> <p>For example, consider the following line from the Zabbix agent log file:</p> <p>" 23480:20100328:154718.045 Zabbix agent started. Zabbix 1.8.2 (revision 11211)."</p> <p>It begins with six character positions for PID, followed by date, time, and the rest of the message. The log time format for this line would be "pppppp:yyyyMMdd:hhmmss".</p> <p>Note that "p" and ":" characters are placeholders and can be any characters except "yMdhms".</p> |
| <i>Populates host inventory field</i> | <p>You can select a host inventory field that the value of item will populate. This will work if automatic inventory population is enabled for the host.</p> <p>This field is not available if <i>Type of information</i> is set to 'Log'.</p> |
| <i>Description</i> | Enter an item description. User macros are supported. |
| <i>Enabled</i> | Mark the checkbox to enable the item so it will be processed. |
| <i>Latest data</i> | <p>Click on the link to view the latest data for the item.</p> <p>This link is only available when editing an already existing item.</p> |

Note:

Item type specific fields are described on [corresponding pages](#).

Note:

When editing an existing **template** level item on a host level, a number of fields are read-only. You can use the link in the form header and go to the template level and edit them there, keeping in mind that the changes on a template level will change the item for all hosts that the template is linked to.

The **Tags** tab allows to define item-level **tags**.

| Item tags | |
|-----------|-------|
| Name | Value |
| component | cpu |

Item value preprocessing

The **Preprocessing** tab allows to define **transformation rules** for the received values.

Testing

Attention:

To perform item testing, ensure that the system time on the server and the proxy is **synchronized**. In the case when the server time is behind, item testing may return an error message "The task has been expired." Having set different time zones on the server and the proxy, however, won't affect the testing result.

It is possible to test an item and, if configured correctly, get a real value in return. Testing can occur even before an item is saved.

Testing is available for host and template items, item prototypes and low-level discovery rules. Testing is not available for active items.

Item testing is available for the following passive item types:

- Zabbix agent
- SNMP agent (v1, v2, v3)
- IPMI agent
- SSH checks
- Telnet checks
- JMX agent
- Simple checks (except `icmping*`, `vmware.*` items)
- Zabbix internal
- Calculated items
- External checks
- Database monitor
- HTTP agent
- Script
- Browser

To test an item, click on the *Test* button at the bottom of the item configuration form. Note that the *Test* button will be disabled for items that cannot be tested (like active checks, excluded simple checks).

Description

Enabled ☒

The item testing form has fields for the required host parameters (host address, port, test with server/proxy (proxy name)) and item-specific details (such as SNMPv2 community or SNMPv3 security credentials). These fields are context aware:

- The values are pre-filled when possible, i.e., for items requiring an agent, by taking the information from the selected agent interface of the host
- The values have to be filled manually for template items
- Plain-text macro values are resolved
- Fields where the value (or part of the value) is a secret or Vault macro are empty and have to be entered manually. If any item parameter contains a secret macro value, the following warning message is displayed: "Item contains user-defined macros with secret values. Values of these macros should be entered manually."
- The fields are disabled when not needed in the context of the item type (e.g., the host address field and the proxy field are disabled for calculated items)

To test the item, click on *Get value*. If the value is retrieved successfully, it will fill the *Value* field, moving the current value (if any) to the *Previous value* field while also calculating the *Prev. time* field, i.e., the time difference between the two values (clicks) and trying to detect an EOL sequence and switch to CRLF if detecting "\n\r" in retrieved value.

Previous value Prev. time

End of line sequence LF CRLF

Values retrieved from a host and test results are truncated to a maximum size of 512KB when sent to the frontend. If a result is truncated, a warning icon is displayed. The warning description is displayed on mouseover. Note that data larger than 512KB is still processed fully by Zabbix server.

If the configuration is incorrect, an error message is displayed describing the possible cause.

Test item

Invalid second parameter.

Get value from host ☒

Host address

Test with Server Proxy

Value

A successfully retrieved value from host can also be used to test [preprocessing steps](#).

Form buttons

Buttons at the bottom of the form allow to perform several operations.

Add

Add an item. This button is only available for new items.

Update

Update the properties of an item.

Clone

Create another item based on the properties of the current item.

Execute now

Execute a check for a new item value immediately. Supported for **passive** checks only (see [more details](#)).

Note that when checking for a value immediately, configuration cache is not updated, thus the value will not reflect very recent changes to item configuration.

Test

Test if item configuration is correct by getting a value.

Clear history and trends

Delete the item history and trends.

Delete

Delete the item.

Cancel

Cancel the editing of item properties.

Text data limits

Text data limits depend on the database backend. Before storing text values in the database they get truncated to match the database value type limit:

| Database | Type of information | | |
|----------------------------|---------------------|------------------|------------------|
| | Character | Log | Text |
| MySQL | 255 characters | 65536 bytes | 65536 bytes |
| PostgreSQL | 255 characters | 65536 characters | 65536 characters |
| SQLite (only Zabbix proxy) | 255 characters | 65536 characters | 65536 characters |

Custom script limit

Available custom script length depends on the database used:

| Database | Limit in characters | Limit in bytes |
|----------------------------|---------------------|----------------|
| MySQL | 65535 | 65535 |
| PostgreSQL | 65535 | not limited |
| SQLite (only Zabbix proxy) | 65535 | not limited |

Unsupported items

Unsupported items are reported as having a *Not supported* status and are still rechecked at their standard *Update interval*.

An item becomes unsupported if its value cannot be retrieved for some reason (e.g. connection error, no pollers configured to process the item). In addition, items that do not receive historical data remain in the *Not supported* status. This is expected behavior—an item transitions to a *Normal* status only when it receives new, valid historical data.

Like problems, unsupported items are re-evaluated only when new data is received—even if there is no historical data available for that item anymore. In other words, items and triggers change their state solely upon receiving new data. However, if a trigger expression includes a *date and time* and/or *nodata()* function, the trigger will be recalculated every 30 seconds (see *triggers calculation time* for details).

1 Item key format

Item key format, including key parameters, must follow syntax rules. The following illustrations depict the supported syntax. Allowed elements and characters at each point can be determined by following the arrows - if some block can be reached through the line, it is allowed, if not - it is not allowed.

To construct a valid item key, one starts with specifying the key name, then there's a choice to either have parameters or not - as depicted by the two lines that could be followed.

Key name

The key name itself has a limited range of allowed characters, which just follow each other. Allowed characters are:

0-9a-zA-Z_-.

Which means:

- all numbers;
- all lowercase letters;
- all uppercase letters;
- underscore;
- dash;
- dot.

Key parameters

An item key can have multiple parameters that are comma separated.

Each key parameter can be either a quoted string, an unquoted string or an array.

The parameter can also be left empty, thus using the default value. In that case, the appropriate number of commas must be added if any further parameters are specified. For example, item key **icmpping[,,200,,500]** would specify that the interval between individual pings is 200 milliseconds, timeout - 500 milliseconds, and all other parameters are left at their defaults.

It is possible to include macros in the parameters. Those can be **user macros** or some of the built-in macros. To see what particular built-in macros are supported in item key parameters, search the page **Supported macros** for "item key parameters".

Parameter - quoted string

If the key parameter is a quoted string, any Unicode character is allowed. If the key parameter string contains a quotation mark, this parameter has to be quoted, and each quotation mark which is a part of the parameter string has to be escaped with a backslash (\) character. If the key parameter string contains comma, this parameter has to be quoted.

Warning:

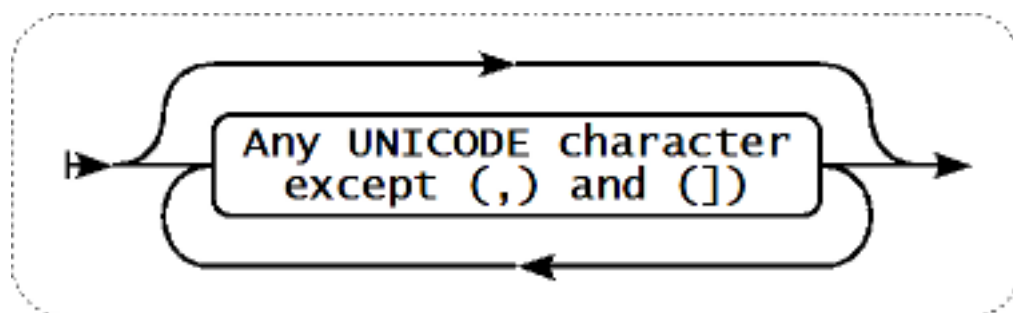

To quote item key parameters, use double quotes only. Single quotes are not supported.

Attention:

Multi-level parameter arrays, e.g. [a, [b, [c,d]], e], are not allowed.

Parameter - unquoted string

If the key parameter is an unquoted string, any Unicode character is allowed except comma and right square bracket (]). Unquoted parameter cannot start with left square bracket ([).

Parameter - array

If the key parameter is an array, it is again enclosed in square brackets, where individual parameters come in line with the rules and syntax of specifying multiple parameters.

2 Custom intervals

Overview

It is possible to create custom rules regarding the times when an item is checked. The two methods for that are *Flexible intervals*, which allow to redefine the default update interval, and *Scheduling*, whereby an item check can be executed at a specific time or sequence of times.

Flexible intervals

Flexible intervals allow to redefine the default update interval for specific time periods. A flexible interval is defined with *Interval* and *Period* where:

- *Interval* - the update interval for the specified time period
- *Period* - the time period when the flexible interval is active (see the [time periods](#) for detailed description of the *Period* format)

If multiple flexible intervals overlap, the smallest *Interval* value is used for the overlapping period. Note that if the smallest value of overlapping flexible intervals is '0', no polling will take place. Outside the flexible intervals the default update interval is used.

Note that if the flexible interval equals the length of the period, the item will be checked exactly once. If the flexible interval is greater than the period, the item might be checked once or it might not be checked at all (thus such configuration is not advisable). If the flexible interval is less than the period, the item will be checked at least once.

If the flexible interval is set to '0', the item is not polled during the flexible interval period and resumes polling according to the default *Update interval* once the period is over. Examples:

| Interval | Period | Description |
|----------|-----------------|--|
| 10 | 1-5,09:00-18:00 | Item will be checked every 10 seconds during working hours. |
| 0 | 1-7,00:00-7:00 | Item will not be checked during the night. |
| 0 | 7-7,00:00-24:00 | Item will not be checked on Sundays. |
| 60 | 1-7,12:00-12:01 | Item will be checked at 12:00 every day. Note that this was used as a workaround for scheduled checks and it is recommended to use scheduling intervals for such checks. |

Scheduling intervals

Scheduling intervals are used to check items at specific times. While flexible intervals are designed to redefine the default item update interval, the scheduling intervals are used to specify an independent checking schedule, which is executed in parallel.

A scheduling interval is defined as: md<filter>wd<filter>h<filter>m<filter>s<filter> where:

- **md** - month days

- **wd** - week days
- **h** - hours
- **m** - minutes
- **s** - seconds

<filter> is used to specify values for its prefix (days, hours, minutes, seconds) and is defined as: [<from>[-<to>]] [/<step>] [,<filter>] where:

- <from> and <to> define the range of matching values (included). If <to> is omitted then the filter matches a <from> - <from> range. If <from> is also omitted then the filter matches all possible values.
- <step> defines the skips of the number value through the range. By default <step> has the value of 1, which means that all values of the defined range are matched.

While the filter definitions are optional, at least one filter must be used. A filter must either have a range or the <step> value defined.

An empty filter matches either '0' if no lower-level filter is defined or all possible values otherwise. For example, if the hour filter is omitted then only '0' hour will match, provided minute and seconds filters are omitted too, otherwise an empty hour filter will match all hour values.

Valid <from> and <to> values for their respective filter prefix are:

| Prefix | Description | <from> | <to> |
|--------|-------------|--------|------|
| md | Month days | 1-31 | 1-31 |
| wd | Week days | 1-7 | 1-7 |
| h | Hours | 0-23 | 0-23 |
| m | Minutes | 0-59 | 0-59 |
| s | Seconds | 0-59 | 0-59 |

The <from> value must be less or equal to <to> value. The <step> value must be greater or equal to 1 and less or equal to <to> - <from>.

Single digit month days, hours, minutes and seconds values can be prefixed with 0. For example md01-31 and h/02 are valid intervals, but md01-031 and wd01-07 are not.

In Zabbix frontend, multiple scheduling intervals are entered in separate rows. In Zabbix API, they are concatenated into a single string with a semicolon ; as a separator.

If a time is matched by several intervals it is executed only once. For example, wd1h9;h9 will be executed only once on Monday at 9am.

Examples:

| Interval | Will be executed |
|---|---|
| m0-59 | every minute |
| h9-17/2 | every 2 hours starting with 9:00 (9:00, 11:00 ...) |
| m0,30 or m/30 | hourly at hh:00 and hh:30 |
| m0,5,10,15,20,25,30,35,40,45,50,55 or m/5 | every five minutes |
| wd1-5h9 | every Monday till Friday at 9:00 |
| wd1-5h9-18 | every Monday till Friday at 9:00,10:00,...,18:00 |
| h9,10,11 or h9-11 | every day at 9:00, 10:00 and 11:00 |
| md1h9m30 | every 1st day of each month at 9:30 |
| md1wd1h9m30 | every 1st day of each month at 9:30 if it is Monday |
| h9m/30 | every day at 9:00, 9:30 |
| h9m0-59/30 | every day at 9:00, 9:30 |
| h9,10m/30 | every day at 9:00, 9:30, 10:00, 10:30 |
| h9-10m30 | every day at 9:30, 10:30 |
| h9m10-40/30 | every day at 9:10, 9:40 |
| h9,10m10-40/30 | every day at 9:10, 9:40, 10:10, 10:40 |
| h9-10m10-40/30 | every day at 9:10, 9:40, 10:10, 10:40 |
| h9m10-40 | every day at 9:10, 9:11, 9:12, ... 9:40 |
| h9m10-40/1 | every day at 9:10, 9:11, 9:12, ... 9:40 |
| h9-12,15 | every day at 9:00, 10:00, 11:00, 12:00, 15:00 |
| h9-12,15m0 | every day at 9:00, 10:00, 11:00, 12:00, 15:00 |

| Interval | Will be executed |
|--|---|
| h9-12,15m0s30 | every day at 9:00:30, 10:00:30, 11:00:30, 12:00:30, 15:00:30 |
| h9-12s30 | every day at 9:00:30, 9:01:30, 9:02:30 ... 12:58:30, 12:59:30 |
| h9m/30;h10 (<i>API-specific syntax</i>) | every day at 9:00, 9:30, 10:00 |
| h9m/30 | every day at 9:00, 9:30, 10:00 |
| h10 (<i>add this as another row in frontend</i>) | |

Aligning time zones for proxies and agent

Note that Zabbix proxies and agent use their local time zones when processing scheduling intervals.

For this reason, when scheduling intervals are applied to items monitored by Zabbix proxy or agent active items, it is recommended to set the time zone of the respective proxies or agent the same as Zabbix server, otherwise the **queue** may report item delays incorrectly.

The time zone for Zabbix proxy or agent can be set using the environment variable TZ in the systemd unit file:

```
[Service]
...
Environment="TZ=Europe/Amsterdam"
```

2 Item value preprocessing

Overview

Preprocessing allows you to apply transformations to the received item values before saving them to the database. These transformations/preprocessing steps are performed by Zabbix server or proxy (if items are monitored by proxy).

This feature supports a variety of use cases, such as:

- converting bytes to bits (e.g., multiplying network traffic values by "8");
- calculating per-second statistics for incrementally increasing values;
- applying regular expressions to extract or modify values;
- executing custom scripts on values;
- discarding unchanged values to optimize database storage.

One or more preprocessing steps can be configured for an item. These steps are executed in the order they are configured.

Attention:

If a preprocessing step fails, an item becomes **unsupported**. This can be avoided by *Custom on fail* error-handling (available for most transformations), allowing you to discard values or set custom values.
For log items, log metadata (without value) will always reset the item unsupported state, making it supported again. This happens even if the initial error occurred after receiving a log value from agent.

All values passed to preprocessing are initially treated as strings. Conversion to the desired value type (as defined in item configuration) is performed at the end of the preprocessing pipeline. However, specific preprocessing steps may trigger earlier conversions, if required. For detailed technical information, see [Preprocessing details](#).

To ensure that your preprocessing configuration works as expected, you can **test it**.

See also: [Preprocessing examples](#)

Configuration

Preprocessing steps are defined in the **Preprocessing** tab of the item **configuration** form.

The screenshot shows the 'Preprocessing' tab of the Zabbix item configuration form. It contains a table of preprocessing steps:

| Preprocessing steps | Name | Parameters | Custom on fail | Actions |
|---------------------|-------------------|------------|--------------------------|---|
| 1: | Change per second | | <input type="checkbox"/> | Test Remove |
| 2: | Custom multiplier | 8 | <input type="checkbox"/> | Test Remove |

Below the table, there is an 'Add' button and a 'Test all steps' link. At the bottom, there is a 'Type of information' dropdown menu set to 'Numeric (unsigned)', and 'Add', 'Test', and 'Cancel' buttons.

Click on *Add* to select a supported transformation.

The *Type of information* field is displayed at the bottom of the tab when at least one preprocessing step is defined. If required, it is possible to change the type of information without leaving the *Preprocessing* tab. See [Creating an item](#) for the detailed parameter description.

Supported transformations

All supported transformations are listed below. Click on the transformation name to see full details about it.

| Name | Description | Type |
|--|--|---------------------------|
| Regular expression | Match the value to the regular expression and replace with the required output. | Text |
| Replace | Find the search string and replace it with another (or nothing). | |
| Trim | Remove specified characters from the beginning and end of the value. | |
| Right trim | Remove specified characters from the end of the value. | |
| Left trim | Remove specified characters from the beginning of the value. | |
| XML XPath | Extract value or fragment from XML data using XPath functionality. | Structured data |
| JSON Path | Extract value or fragment from JSON data using JSONPath functionality. | |
| CSV to JSON | Convert CSV file data into JSON format. | |
| XML to JSON | Convert data in XML format to JSON. | |
| SNMP walk value | Extract value by the specified OID/MIB name and apply formatting options. | SNMP |
| SNMP walk to JSON | Convert SNMP values to JSON. | |
| SNMP get value | Apply formatting options to the SNMP get value. | |
| Custom multiplier | Multiply the value by the specified integer or floating-point value. | Arithmetic Change |
| Simple change | Calculate the difference between the current and previous value. | |
| Change per second | Calculate the value change (difference between the current and previous value) speed per second. | |
| Boolean to decimal | Convert the value from boolean format to decimal. | Numeral systems |
| Octal to decimal | Convert the value from octal format to decimal. | |
| Hexadecimal to decimal | Convert the value from hexadecimal format to decimal. | |
| JavaScript | Enter JavaScript code. | Custom scripts Validation |
| In range | Define a range that a value should be in. | |
| Matches regular expression | Specify a regular expression that a value must match. | |
| Does not match regular expression | Specify a regular expression that a value must not match. | |
| Check for error in JSON | Check for an application-level error message located at JSONPath. | |
| Check for error in XML | Check for an application-level error message located at XPath. | Throttling |
| Check for error using a regular expression | Check for an application-level error message using a regular expression. | |
| Check for not supported value | Check if no item value could be retrieved. | |
| Discard unchanged | Discard a value if it has not changed. | |
| Discard unchanged with heartbeat | Discard a value if it has not changed within the defined time period. | |
| Prometheus pattern | Use the following query to extract the required data from Prometheus metrics. | Prometheus |
| Prometheus to JSON | Convert the required Prometheus metrics to JSON. | |

Note that for *Change* and *Throttling* preprocessing steps, Zabbix has to remember the last value to calculate/compare the new value as required. These previous values are handled by the preprocessing manager. If Zabbix server or proxy is restarted or there is any change made to preprocessing steps, the last value of the corresponding item is reset, resulting in:

- for *Simple change*, *Change per second* steps - the next value will be ignored because there is no previous value to calculate the change from;
- for *Discard unchanged*, *Discard unchanged with heartbeat* steps - the next value will never be discarded, even if it should have been because of discarding rules.

Regular expression

Match the value to the regular expression and replace with the required output.

Parameters:

- **pattern** - the regular expression;

- **output** - the output formatting template. An \N (where N=1...9) escape sequence is replaced with the Nth matched group. A \0 escape sequence is replaced with the matched text.

Comments:

- A failure to match the input value will make the item unsupported;

- The regular expression supports extraction of maximum 10 captured groups with the \N sequence;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

- Please refer to [regular expressions](#) section for some existing examples.

Replace

Find the search string and replace it with another (or nothing).

Parameters:

- **search string** - the string to find and replace, case-sensitive (required);

- **replacement** - the string to replace the search string with. The replacement string may also be empty effectively allowing to delete the search string when found.

Comments:

- All occurrences of the search string will be replaced;
- It is possible to use escape sequences to search for or replace line breaks, carriage return, tabs and spaces "\n \r \t \s"; backslash can be escaped as "\\" and escape sequences can be escaped as "\\n";
- Escaping of line breaks, carriage return, tabs is automatically done during low-level discovery.

Trim

Remove specified characters from the beginning and end of the value.

Right trim

Remove specified characters from the end of the value.

Left trim

Remove specified characters from the beginning of the value.

XML XPath

Extract value or fragment from XML data using XPath functionality.

Comments:

- For this option to work, Zabbix server (or Zabbix proxy) must be compiled with libxml support;

- Namespaces are not supported;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Examples:

```
number(/document/item/value) #will extract '10' from <document><item><value>10</value></item></document>
number(/document/item/@attribute) #will extract '10' from <document><item attribute="10"></item></document>
/document/item #will extract '<item><value>10</value></item>' from <document><item><value>10</value></item>
```

JSON Path

Extract value or fragment from JSON data using [JSONPath functionality](#).

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

CSV to JSON

Convert CSV file data into JSON format.

For more information, see: [CSV to JSON preprocessing](#).

XML to JSON

Convert data in XML format to JSON.

For more information, see: [Serialization rules](#).

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

SNMP walk value

Extract value by the specified OID/MIB name and apply formatting options:

- **Unchanged** - return hex-string as unescaped hex string (*note* that display hints are still applied);

- **UTF-8 from hex-STRING** - convert hex-string to UTF-8 string;

- **MAC from hex-STRING** - validate hex-string as MAC address and return a proper MAC address string (where ' ' are replaced by ':');

- **Integer from BITS** - convert the first 8 bytes of a bit string expressed as a sequence of hex characters (e.g., "1A 2B 3C 4D") into a 64-bit unsigned integer. In bit strings longer than 8 bytes, consequent bytes will be ignored.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

SNMP walk to JSON

Convert SNMP values to JSON.

Specify a field name in the JSON and the corresponding SNMP OID path. Field values will be populated by values in the specified SNMP OID path.

Comments:

- Similar value formatting options as in the *SNMP walk value* step are available;

- You may use this preprocessing step for [SNMP OID discovery](#);

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

SNMP get value

Apply formatting options to the SNMP get value:

- **UTF-8 from Hex-STRING** - convert hex-string to UTF-8 string;

- **MAC from Hex-STRING** - validate hex-string as MAC address and return a proper MAC address string (where ' ' are replaced by ':');

- **Integer from BITS** - convert the first 8 bytes of a bit string expressed as a sequence of hex characters (e.g., "1A 2B 3C 4D") into a 64-bit unsigned integer. In bit strings longer than 8 bytes, consequent bytes will be ignored.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Custom multiplier

Multiply the value by the specified integer or floating-point value.

Comments:

- Use this option to convert values received in KB, MBps, etc., into B, Bps. Otherwise, Zabbix cannot correctly set [prefixes](#) (K, M, G, etc.).

- Note that if the item type of information is *Numeric (unsigned)*, incoming values with a fractional part will be trimmed (i.e., '0.9' will become '0') before the custom multiplier is applied;

- If you use a custom multiplier or store value as *Change per second* for items with the type of information set to *Numeric (unsigned)* and the resulting calculated value is actually a float number, the calculated value is still accepted as a correct one by trimming the decimal part and storing the value as an integer;

- Supported: scientific notation, for example, 1e+70; user macros and LLD macros; strings that include macros, for example, {#MACRO}e+10, {\$MACRO1}e+{\$MACRO2}. The macros must resolve to an integer or a floating-point number.
- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Simple change

Calculate the difference between the current and previous value.

Comments:

- This step can be useful to measure a constantly growing value;

- Evaluated as **value-prev_value**, where *value* - the current value; *prev_value* - the previously received value;

- Only one change operation per item ("Simple change" or "Change per second") is allowed;
- If the current value is smaller than the previous value, Zabbix discards that difference (stores nothing) and waits for another value;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Change per second

Calculate the value change (difference between the current and previous value) speed per second.

Comments:

- This step is useful for calculating the speed per second of a constantly growing value;

- As this calculation may produce floating-point numbers, it is recommended to set the 'Type of information' to *Numeric (float)*, even if the incoming raw values are integers. This is especially relevant for small numbers where the decimal part matters. If the floating-point values are large and may exceed the 'float' field length in which case the entire value may be lost, it is actually suggested to use *Numeric (unsigned)* and thus trim only the decimal part.

- Evaluated as **(value-prev_value)/(time-prev_time)**, where *value* - the current value; *prev_value* - the previously received value; *time* - the current timestamp; *prev_time* - the timestamp of the previous value;

- Only one change operation per item ("Simple change" or "Change per second") is allowed;
- If the current value is smaller than the previous value, Zabbix discards that difference (stores nothing) and waits for another value. This helps to work correctly with, for instance, a wrapping (overflow) of 32-bit SNMP counters.

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Boolean to decimal

Convert the value from boolean format to decimal.

Comments:

- The textual representation is translated into either 0 or 1. Thus, 'TRUE' is stored as 1 and 'FALSE' is stored as 0. All values are matched in a case-insensitive way. Currently recognized values are, for *TRUE* - true, t, yes, y, on, up, running, enabled, available, ok, master; for *FALSE* - false, f, no, n, off, down, unused, disabled, unavailable, err, slave. Additionally, any non-zero numeric value is considered to be TRUE and zero is considered to be FALSE.

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Octal to decimal

Convert the value from octal format to decimal.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Hexadecimal to decimal

Convert the value from hexadecimal format to decimal.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

JavaScript

Enter JavaScript code in the modal editor that opens when clicking in the parameter field or on the pencil icon next to it.

Comments:

- The available JavaScript length depends on the **database used**;

- For more information, see: **JavaScript preprocessing**.

In range

Define a range that a value should be in by specifying minimum/maximum values (inclusive).

Comments:

- Numeric values are accepted (including any number of digits, optional decimal part and optional exponential part, negative values);

- The minimum value should be less than the maximum;

- At least one value must exist;

- User macros and low-level discovery macros can be used;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Matches regular expression

Specify a regular expression that a value must match.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Does not match regular expression

Specify a regular expression that a value must not match.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Check for error in JSON

Check for an application-level error message located at JSONPath. Stop processing if succeeded and the message is not empty; otherwise, continue processing with the value that was before this preprocessing step.

Comments:

- These external service errors are reported to the user as is, without adding preprocessing step information;

- No error will be reported in case of failing to parse invalid JSON;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Check for error in XML

Check for an application-level error message located at XPath. Stop processing if succeeded and the message is not empty; otherwise, continue processing with the value that was before this preprocessing step.

Comments:

- These external service errors are reported to the user as is, without adding preprocessing step information;

- No error will be reported in case of failing to parse invalid XML;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Check for error using a regular expression

Check for an application-level error message using a regular expression. Stop processing if succeeded and the message is not empty; otherwise, continue processing with the value that was before this preprocessing step.

Parameters:

- **pattern** - the regular expression;

- **output** - the output formatting template. An \N (where N=1...9) escape sequence is replaced with the Nth matched group. A \0 escape sequence is replaced with the matched text.

Comments:

- These external service errors are reported to the user as is, without adding preprocessing step information;

- If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.

Check for not supported value

Check if no item value could be retrieved. Specify how the failure should be processed, based on inspecting the returned error message.

Parameters:

- **scope** - select the error processing scope:
any error - any error;
error matches - only the error that matches the regular expression specified in *pattern*;
error does not match - only the error that does not match the regular expression specified in *pattern*

- **pattern** - the regular expression to match the error to. If *any error* is selected in the scope parameter, this field is not displayed. If displayed, this field is mandatory.

Comments:

- Normally, the absence/failure to retrieve a value would lead to the item becoming unsupported. This preprocessing step allows you to modify this behavior. If you mark the *Custom on fail* checkbox (always marked and grayed out for this preprocessing step), it is possible to specify custom error-handling options: either to discard the value, set a specified value, or set a specified error message. In case of a failed preprocessing step, the item will not become unsupported if the option to discard the value or set a specified value is selected.
- This preprocessing step only checks if no item value could be retrieved. It does not check, for example, if the type of the retrieved value (e.g., string) matches the item's type of information (e.g., numeric); for details, see [Preprocessing examples](#). If there is a type mismatch, the item may still become unsupported after all preprocessing steps are executed. To check for a type mismatch, you may use, for example, the *Custom multiplier* preprocessing step; see [Preprocessing examples](#).
- Capturing regular expression groups is supported in the *Set value to* or *Set error to* fields. Use \N (where N=1...9) to retrieve the Nth matched group; use \0 to retrieve the matched text;
- These steps are always executed as the first preprocessing steps and are placed above all others after saving changes to the item;
- Multiple *Check for not supported value* steps are supported, in the specified order. A step for *any error* will be automatically placed as the last step in this group.

Discard unchanged

Discard a value if it has not changed.

Comments:

- If a value is discarded, it is not saved in the database and Zabbix server has no knowledge that this value was received. No trigger expressions will be evaluated, as a result, no problems for related triggers will be created/resolved. Functions will work only based on data that is actually saved in the database. As trends are built based on data in the database, if there is no value saved for an hour then there will also be no trends data for that hour.

- Only one throttling option can be specified per item.

Discard unchanged with heartbeat

Discard a value if it has not changed within the defined time period (in seconds).

Comments:

- Positive integer values are supported to specify the seconds (minimum - 1 second);

- Time suffixes can be used (e.g., 30s, 1m, 2h, 1d);

- User macros and low-level discovery macros can be used;

- If a value is discarded, it is not saved in the database and Zabbix server has no knowledge that this value was received. No trigger expressions will be evaluated, as a result, no problems for related triggers will be created/resolved. Functions will work only based on data that is actually saved in the database. As trends are built based on data in the database, if there is no value saved for an hour then there will also be no trends data for that hour.

- Only one throttling option can be specified per item.

Prometheus pattern

Use the following query to extract the required data from Prometheus metrics.

See [Prometheus checks](#) for more details.

Prometheus to JSON

Convert the required Prometheus metrics to JSON.

See [Prometheus checks](#) for more details.

Macro support

[User macros](#) and user macros with context are supported in:

- preprocessing step parameters, including JavaScript code;

- custom error-handling parameters (*Set value to* and *Set error to* fields).

Note:

The macro context is ignored when a macro is replaced with its value. The macro value is inserted in the code as is, it is not possible to add additional escaping before placing the value in the JavaScript code. Please be advised that this can cause JavaScript errors in some cases.

Testing

See [preprocessing testing](#).

1 Preprocessing testing

Testing

Testing preprocessing steps is useful to make sure that complex preprocessing pipelines yield the results that are expected from them, without waiting for the item value to be received and preprocessed.

It is possible to test:

- against a hypothetical value
- against a real value from a host

Each preprocessing step can be tested individually as well as all steps can be tested together. When you click on the *Test* or *Test all steps* button respectively in the Actions block, a testing window is opened.

Testing hypothetical value

| Parameter | Description |
|----------------------------|---|
| <i>Get value from host</i> | If you want to test a hypothetical value, leave this checkbox unmarked. See also: Testing real value . |
| <i>Value</i> | Enter the input value to test. Clicking in the parameter field or on the view/edit button  will open a text area window for entering the value or code block. |
| <i>Not supported</i> | Mark this checkbox to test an unsupported value. This option is useful to test the <i>Check for not supported value</i> preprocessing step. |

| Parameter | Description |
|-----------------------------|---|
| <i>Error</i> | Enter the error text. This field is enabled when <i>Get value from host</i> is unchecked, but <i>Not supported</i> is checked. If <i>Get value from host</i> is checked, this field gets filled with the actual error message (read-only) from the host. |
| <i>Time</i> | Time of the input value is displayed: <i>now</i> (read-only). |
| <i>Previous value</i> | Enter a previous input value to compare to. Only for <i>Change</i> and <i>Throttling</i> preprocessing steps. |
| <i>Previous time</i> | Enter the previous input value time to compare to. Only for <i>Change</i> and <i>Throttling</i> preprocessing steps. The default value is based on the 'Update interval' field value of the item (if '1m', then this field is filled with <i>now-1m</i>). If nothing is specified or the user has no access to the host, the default is <i>now-30s</i> . |
| <i>Macros</i> | If any macros are used, they are listed along with their values. The values are editable for testing purposes, but the changes will only be saved within the testing context. |
| <i>End of line sequence</i> | Select the end of line sequence for multiline input values: LF - LF (line feed) sequence CRLF - CRLF (carriage-return line-feed) sequence. |
| <i>Preprocessing steps</i> | Preprocessing steps are listed; the testing result is displayed for each step after the <i>Test</i> button is clicked. Test results are truncated to a maximum size of 512KB when sent to the frontend. If a result is truncated, a warning icon is displayed. The warning description is displayed on mouseover. Note that data larger than 512KB is still processed fully by Zabbix server. If the step failed in testing, an error icon is displayed. The error description is displayed on mouseover. In case "Custom on fail" is specified for the step and that action is performed, a new line appears right after the preprocessing test step row, showing what action was done and what outcome it produced (error or value). |
| <i>Result</i> | The final result of testing preprocessing steps is displayed in all cases when all steps are tested together (when you click on the <i>Test all steps</i> button). The type of conversion to the value type of the item is also displayed, for example <i>Result converted to Numeric (unsigned)</i> . Test results are truncated to a maximum size of 512KB when sent to the frontend. If a result is truncated, a warning icon is displayed. The warning description is displayed on mouseover. Note that data larger than 512KB is still processed fully by Zabbix server. |

Click on *Test* to see the result after each preprocessing step.

Test values are stored between test sessions for either individual steps or all steps, allowing the user to change preprocessing steps or item configuration and then return to the testing window without having to re-enter information. Values are lost on a page refresh though.

The testing is done by Zabbix server. The frontend sends a corresponding request to the server and waits for the result. The request contains the input value and preprocessing steps (with expanded user macros). For *Change* and *Throttling* steps, an optional previous value and time can be specified. The server responds with results for each preprocessing step.

All technical errors or input validation errors are displayed in the error box at the top of the testing window.

Testing real value

To test preprocessing against a real value:

- Mark the *Get value from host* checkbox
- Enter or verify host parameters (host address, port, proxy name/no proxy) and item-specific details (such as SNMPv2 community or SNMPv3 security credentials). These fields are context-aware:
 - The values are pre-filled when possible, i.e., for items requiring an agent, by taking the information from the selected agent interface of the host
 - The values have to be filled manually for template items
 - Plain-text macro values are resolved
 - Where the field value (or part of the value) is a secret or Vault macro, the field will be empty and has to be filled out manually. If any item parameter contains a secret macro value, the following warning message is displayed: "Item contains user-defined macros with secret values. Values of these macros should be entered manually."
 - The fields are disabled when not needed in the context of the item type (e.g., the host address and the proxy fields are disabled for calculated items)
- Click on *Get value and test* to test the preprocessing

Get value and test

Cancel

If you have specified a value mapping in the item configuration form ('Show value' field), the item test dialog will show another line after the final result, named 'Result with value map applied'.

Parameters that are specific to getting a real value from a host:

| Parameter | Description |
|--|---|
| <i>Get value from host</i> | Mark this checkbox to get a real value from the host. |
| <i>Host address</i> | Enter the host address. |
| <i>Port</i> | This field is automatically filled by the address of the item host interface. Enter the host port. |
| <i>Additional fields for SNMP interfaces (SNMP version, SNMP community, Context name, etc.)</i> | This field is automatically filled by the port of item host interface. See Configuring SNMP monitoring for additional details on configuring an SNMP interface (v1, v2 and v3). |
| <i>Proxy</i> | These fields are automatically filled from the item host interface. Specify the proxy if the host is monitored by a proxy. |
| <i>Value</i> | This field is automatically filled by the proxy of the host (if any). Value retrieved from the host. Clicking in the parameter field or on the view/edit button  will open a text area window of the value or code block. Values are truncated to a maximum size of 512KB and only in the frontend. If a result is truncated, a warning icon is displayed. The warning description is displayed on mouseover. Note that data larger than 512KB is still processed fully by Zabbix server. |

For the rest of the parameters, see [Testing hypothetical value](#) above.

2 Preprocessing details

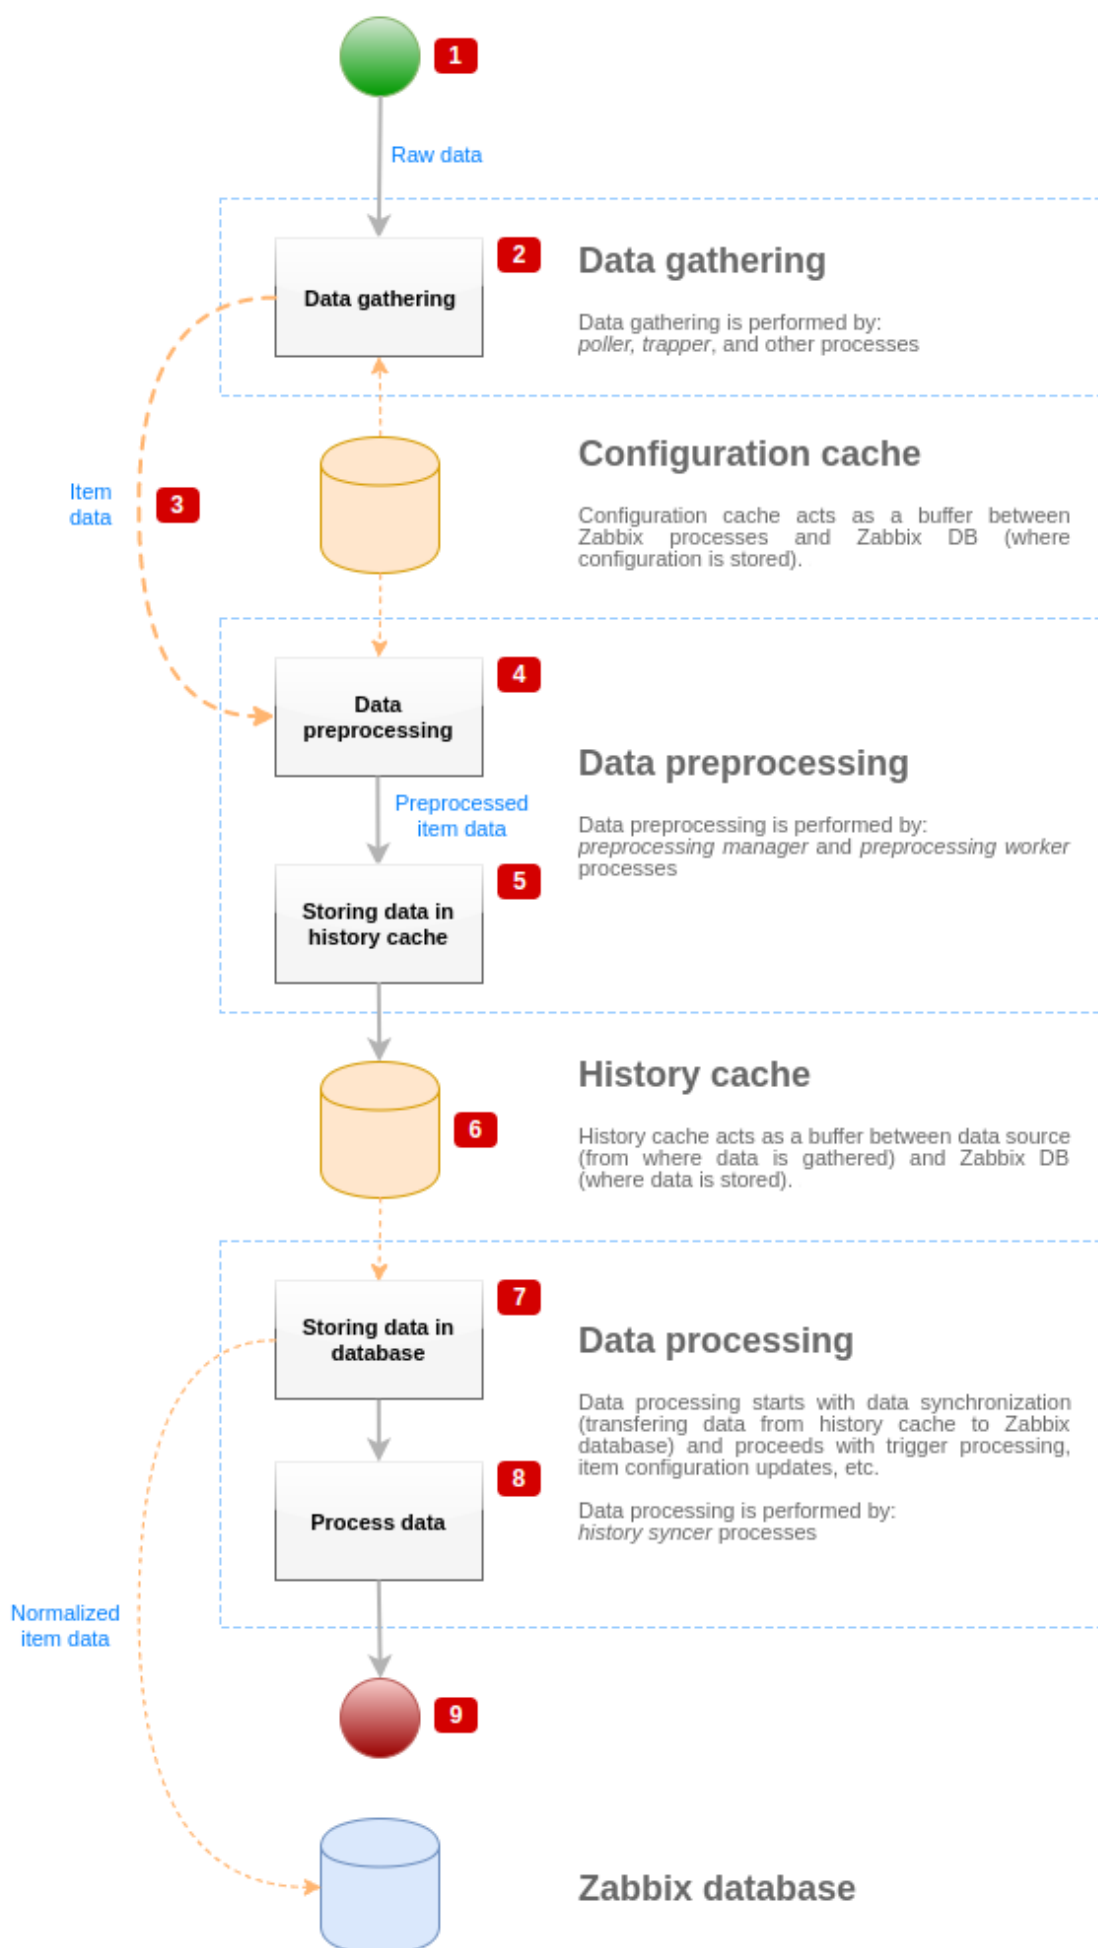

Overview

This section provides item value preprocessing details. The item value preprocessing allows to define and execute **transformation rules** for the received item values.

Preprocessing is managed by the preprocessing manager process along with preprocessing workers that perform the preprocessing steps. All values (with or without preprocessing) from different data gatherers pass through the preprocessing manager before being added to the history cache. Socket-based IPC communication is used between data gatherers (pollers, trappers, etc.) and the preprocessing process. Either Zabbix server or Zabbix proxy (for the items monitored by the proxy) performs the preprocessing steps.

Item value processing

To visualize the data flow from data source to the Zabbix database, we can use the following simplified diagram:

The diagram above shows only processes, objects and actions related to item value processing in a **simplified** form. The diagram does not show conditional direction changes, error handling or loops. The local data cache of the preprocessing manager is not shown either because it doesn't affect the data flow directly. The aim of this diagram is to show processes involved in the item value processing and the way they interact.

- Data gathering starts with raw data from a data source. At this point, the data contains only ID, timestamp and value (can be multiple values as well).
- No matter what type of data gatherer is used, the idea is the same for active or passive checks, for trapper items, etc., as it only changes the data format and the communication starter (either data gatherer is waiting for a connection and data, or data gatherer initiates the communication and requests the data). The raw data is validated, the item configuration is retrieved from the configuration cache (data is enriched with the configuration data).
- A socket-based IPC mechanism is used to pass data from data gatherers to the preprocessing manager. At this point the data gatherer continues to gather data without waiting for the response from preprocessing manager.
- Data preprocessing is performed. This includes the execution of preprocessing steps and dependent item processing.

Note:

An item can change its state to NOT SUPPORTED while preprocessing is performed if any of preprocessing steps fail.

- The history data from the local data cache of the preprocessing manager is being flushed into the history cache.
- At this point the data flow stops until the next synchronization of history cache (when the history syncer process performs data synchronization).
- The synchronization process starts with data normalization before storing data in Zabbix database. The data normalization performs conversions to the desired item type (type defined in item configuration), including truncation of textual data based on predefined sizes allowed for those types (HISTORY_STR_VALUE_LEN for string, HISTORY_TEXT_VALUE_LEN for text and HISTORY_LOG_VALUE_LEN for log values). The data is being sent to the Zabbix database after the normalization is done.

Note:

An item can change its state to NOT SUPPORTED if data normalization fails (for example, when a textual value cannot be converted to number).

- The gathered data is being processed - triggers are checked, the item configuration is updated if item becomes NOT SUPPORTED, etc.
- This is considered the end of data flow from the point of view of item value processing.

Item value preprocessing

Data preprocessing is performed in the following steps:

- The item value is passed to the preprocessing manager using a UNIX socket-based IPC mechanism.
- If the item has neither preprocessing nor dependent items, its value is either added to the history cache or sent to the LLD manager. Otherwise:
 - A preprocessing task is created and added to the queue and preprocessing workers are notified about the new task.
 - At this point the data flow stops until there is at least one unoccupied (i.e., not executing any tasks) preprocessing worker.
 - When a preprocessing worker is available, it takes the next task from the queue.
 - After the preprocessing is done (both failed and successful execution of preprocessing steps), the preprocessed value is added to the finished task queue and the manager is notified about a new finished task.
 - The preprocessing manager converts the result to desired format (defined by item value type) and either adds it to the history cache or sends to the LLD manager.
 - If there are dependent items for the processed item, then dependent items are added to the preprocessing queue with the preprocessed master item value. Dependent items are enqueued bypassing the normal value preprocessing requests, but only for master items with the value set and not in a NOT SUPPORTED state.

Note that in the diagram the master item preprocessing is slightly simplified by skipping the preprocessing caching.

Preprocessing queue

The preprocessing queue is organized as:

- the list of pending tasks:
 - tasks created directly from value preprocessing requests in the order they were received
- the list of immediate tasks (processed before pending tasks):
 - testing tasks (created in response to item/preprocessing testing requests by the frontend)
 - dependent item tasks
 - sequence tasks (tasks that must be executed in a strict order):
 - * having preprocessing steps using the last value:
 - change
 - throttling
 - JavaScript (bytecode caching)
 - * dependent item preprocessing caching
- the list of finished tasks

Preprocessing caching

Preprocessing caching was introduced to improve the preprocessing performance for multiple dependent items having similar preprocessing steps (which is a common LLD outcome).

Caching is done by preprocessing one dependent item and reusing some of the internal preprocessing data for the rest of the dependent items. The preprocessing cache is supported only for the first preprocessing step of the following types:

- Prometheus pattern (indexes input by metrics)
- JSONPath (pares the data into object tree and indexes the first expression `[?(@.path == "value")]`)

Preprocessing workers

The Zabbix server configuration file allows users to set the count of preprocessing worker threads. The `StartPreprocessors` configuration parameter should be used to set the number of pre-started instances of preprocessing workers, which should at least match the number of available CPU cores.

If preprocessing tasks are not CPU-bound and involve frequent network requests, configuring additional workers is recommended. The optimal number of preprocessing workers can be determined by many factors, including the count of "preprocessable" items (items that require to execute any preprocessing steps), the count of data gathering processes, the average step count for item preprocessing, etc. Insufficient workers can lead to high memory usage. For troubleshooting excessive memory usage on your Zabbix installation, see [Profiling excessive memory usage with tcmalloc](#).

But assuming that there are no heavy preprocessing operations like parsing large XML/JSON chunks, the number of preprocessing workers can match the total number of data gatherers. This way, there will mostly (except for the cases when data from the gatherer comes in bulk) be at least one unoccupied preprocessing worker for collected data.

Warning:

Too many data gathering processes (pollers, unreachable pollers, ODBC pollers, HTTP pollers, Java pollers, pingers, trappers, proxypollers) together with IPMI manager, SNMP trapper and preprocessing workers can exhaust the per-process file descriptor limit for the preprocessing manager.
Exhausting the per-process file descriptor limit will cause Zabbix server to stop, typically shortly after startup but sometimes taking longer. To avoid such issues, review the [Zabbix server configuration file](#) to optimize the number of concurrent checks and processes. Additionally, if necessary, ensure that the file descriptor limit is set sufficiently high by checking and adjusting system limits.

Value processing pipeline

Item value processing is executed in multiple steps (or phases) by multiple processes. This can cause:

- A dependent item can receive values, while THE master value cannot. This can be achieved by using the following use case:
 - Master item has value type UINT (trapper item can be used), dependent item has value type TEXT.
 - No preprocessing steps are required for both master and dependent items.
 - Textual value (for example, "abc") should be passed to master item.
 - As there are no preprocessing steps to execute, preprocessing manager checks if master item is not in NOT SUPPORTED state and if value is set (both are true) and enqueues dependent item with the same value as master item (as there are no preprocessing steps).
 - When both master and dependent items reach history synchronization phase, master item becomes NOT SUPPORTED because of the value conversion error (textual data cannot be converted to unsigned integer).

As a result, the dependent item receives a value, while the master item changes its state to NOT SUPPORTED.

- A dependent item receives value that is not present in the master item history. The use case is very similar to the previous one, except for the master item type. For example, if CHAR type is used for master item, then master item value will be truncated at the history synchronization phase, while dependent items will receive their values from the initial (not truncated) value of the master item.

3 Preprocessing examples

Overview

This section presents examples of using preprocessing steps to accomplish some practical tasks.

Filtering VMware event log records

This example uses the [Matches regular expression](#) preprocessing step to filter unnecessary events from the VMware event log.

1. On a working VMware Hypervisor host, check that the `vmware.eventlog` item is present and working properly. Note that the event log item could already be present on the hypervisor if a `VMware` template has been linked during the host creation.
2. On the VMware Hypervisor host, create a [dependent item](#) of `Log` type and set the event log item as its master item.

3. In the *Preprocessing* tab of the dependent item, click *Add* to create a preprocessing step and select *Matches regular expression* from the drop-down. Then, specify one of the following patterns:

- For filtering all log events:

```
.* logged in .*
```

- For filtering lines containing usernames after "User":

```
\bUser\s+\K\S+
```

Attention:

If the regular expression is not matched, then the dependent item becomes unsupported with a corresponding error message. To avoid this, mark the *Custom on fail* checkbox and select an option such as discarding the value or setting a custom one. Please note that **discarded** values are not stored in the database; as a result, triggers are not evaluated and trend data is not generated.

Alternatively, you may use the **Regular expression** preprocessing step to extract matching groups and control output:

- For extracting and outputting the entire log event containing "logged in", specify the following parameters:

Pattern: `.*logged in.*`

Output: `\0`

- For extracting and outputting usernames following "User":

Pattern: `User (.*?) (?:\s|)`

Output: `\1`

Checking retrieved value type

This example uses the **Custom multiplier** preprocessing step to check if the retrieved item value type is numeric.

In the *Preprocessing* tab of an item, select the *Custom multiplier* preprocessing step and specify the following parameter (multiplies the retrieved value by 1):

```
1
```

Attention:

If preprocessing fails (e.g., input is not numeric), then the item becomes unsupported with a corresponding error message. To avoid this, mark the *Custom on fail* checkbox and select an option such as discarding the value or setting a custom one. Please note that **discarded** values are not stored in the database; as a result, triggers are not evaluated and trend data is not generated.

Checking for not supported value

This example uses the **Check for not supported value** preprocessing step to check if the item value could not be retrieved.

When a Zabbix server/proxy poller process attempts to collect an item value, it may:

- Return a valid result.
- Return a result that initially seems valid but may become unsupported later (e.g., due to a value type mismatch after preprocessing).
- Return an error of collecting the value, causing the item to become unsupported. Common causes include:
 - Unknown item key (for Zabbix agent, Simple check, or Zabbix internal items)
 - Unknown OID (SNMP agent), unknown sensor (IPMI agent), or no JMX metric (JMX agent)
 - Cannot read trap file (SNMP trap)
 - Script not found (External check)
 - No such URL (HTTP agent, Browser)
 - Login failed (SSH agent, TELNET agent)
 - Invalid formula syntax (Calculated), JavaScript syntax error (Script), or invalid SQL (Database monitor)

To detect and handle errors of collecting item values, you can use the *Check for not supported value* preprocessing step. Note that this step is always executed first and only detects errors that occur before preprocessing begins.

In the *Preprocessing* tab of an item, select the *Check for not supported value* preprocessing step and specify one of the following parameters:

- For any errors:

Parameter: any error

- For errors containing "cannot connect":

Parameter: error matches

Pattern: (?i)cannot connect

Then, use the *Custom on fail* option to discard the value (in this case, the error), set a custom value, or return a custom error message. Please note that **discarded** values are not stored in the database; as a result, triggers are not evaluated and trend data is not generated.

4 JSONPath functionality

Overview

This section outlines the supported JSONPath functionality within item value preprocessing steps.

JSONPath is composed of segments separated by dots. A segment can take the form of a simple word, representing a JSON value name, the wildcard character (*), or a more intricate construct enclosed within square brackets. The dot before a bracketed segment is optional and can be omitted.

| JSONPath example | Description |
|---|---|
| <code>\$.object.name</code> | Return <code>object.name</code> contents. |
| <code>\$.object['name']</code> | Return <code>object.name</code> contents. |
| <code>\$.object.['name']</code> | Return <code>object.name</code> contents. |
| <code>\$["object"]['name']</code> | Return <code>object.name</code> contents. |
| <code>\$.['object'].["name"]</code> | Return <code>object.name</code> contents. |
| <code>\$.object.history.length()</code> | Return the number of <code>object.history</code> array elements. |
| <code>\$[?(@.name == 'Object')].price.first()</code> | Return the value of the <code>price</code> property from the first object named "Object". |
| <code>\$[?(@.name == 'Object')].history.first().length()</code> | Return the number of history array elements from the first object named "Object". |
| <code>\$[?(@.price > 10)].length()</code> | Return the number of objects with a price greater than 10. |

See also: [Escaping special characters from LLD macro values in JSONPath](#).

Supported segments

| Segment | Description |
|--|---|
| <code><name></code> | Match object property by name. |
| <code>*</code> | Match all object properties. |
| <code>['<name>']</code> | Match object property by name. |
| <code>['<name>', '<name>', ...]</code> | Match object property by any of the listed names. |
| <code>[<index>]</code> | Match array element by index. |
| <code>[<number>, <number>, ...]</code> | Match array element by any of the listed indexes. |
| <code>[*]</code> | Match all object properties or array elements. |
| <code>[<start> : <end>]</code> | Match array elements by the defined range: <start> - the first index to match (including); if not specified, matches all array elements from the beginning; if negative, specifies starting offset from the end of array; <end> - the last index to match (excluding); if not specified, matches all array elements to the end; if negative, specifies starting offset from the end of array. |
| <code>[? (<expression>)]</code> | Match objects/array elements by applying a filter expression. |

To find a matching segment ignoring its ancestry (detached segment), it must be prefixed with two dots (. .). For example, `$. . name` or `$. . ['name']` return values of all `name` properties.

Matched element names can be extracted by adding a tilde (~) suffix to the JSONPath. It returns the name of the matched object or an index in string format of the matched array item. The output format follows the same rules as other JSONPath queries - definite path results are returned 'as is', and indefinite path results are returned in an array. However, there is minimal value in extracting the name of an element that matches a definitive path, as it is already known.

Filter expression

The filter expression is an arithmetical expression in infix notation.

Supported operands:

| Operand | Description |
|-----------------------------|---|
| "<text>" '<text>' | Text constant. Example: 'value: \\ '1\\ '' "value: '1'" |
| <number> | Numeric constant supporting scientific notation. Example: 123 |
| <jsonpath starting with \$> | Value referred to by the JSONPath from the input document root node; only definite paths are supported. |
| <jsonpath starting with @> | Example: \$.object.name Value referred to by the JSONPath from the current object/element; only definite paths are supported. Example: @.name |

Supported operators:

| Operator | Type | Description | Result |
|----------|--------|----------------------------|---------------|
| - | Binary | Subtraction | Number |
| + | Binary | Addition | Number |
| / | Binary | Division | Number |
| * | Binary | Multiplication | Number |
| == | Binary | Equality | Boolean (1/0) |
| != | Binary | Inequality | Boolean (1/0) |
| | Binary | Less than | Boolean (1/0) |
| <= | Binary | Less than or equal to | Boolean (1/0) |
| > | Binary | Greater than | Boolean (1/0) |
| >= | Binary | Greater than or equal to | Boolean (1/0) |
| =~ | Binary | Matches regular expression | Boolean (1/0) |
| ! | Unary | Boolean NOT | Boolean (1/0) |
| | Binary | Boolean OR | Boolean (1/0) |
| && | Binary | Boolean AND | Boolean (1/0) |

Functions

Functions can be used at the end of JSONPath. Multiple functions can be chained if the preceding function returns value that is accepted by the following function.

Supported functions:

| Function | Description | Input | Output |
|----------|--|------------------|--|
| avg | Average value of numbers in an input array | Array of numbers | Number |
| min | Minimum value of numbers in an input array | Array of numbers | Number |
| max | Maximum value of numbers in an input array | Array of numbers | Number |
| sum | Sum of numbers in an input array | Array of numbers | Number |
| length | Number of elements in an input array | Array | Number |
| first | The first element of an array | Array | A JSON construct (object, array, value) depending on the contents of the input array |

JSONPath aggregate functions accept quoted numeric values. These values are automatically converted from strings to numeric types when aggregation is needed. Incompatible input will cause the function to generate an error.

Output value

JSONPaths can be divided into definite and indefinite paths. A definite path can return only null or a single match. An indefinite path can return multiple matches: JSONPaths with detached, multiple name/index lists, array slices, or expression segments. However, when a function is used, the JSONPath becomes definite, as functions always output a single value.

A definite path returns the object/array/value it is referencing. In contrast, an indefinite path returns an array of the matched objects/arrays/values.

Attention:

The property order in JSONPath query results may not align with the original JSON property order due to internal optimization methods. For example, the JSONPath `$.books[1]["author", "title"]` may return `["title", "author"]`. If preserving the original property order is essential, alternative post-query processing methods should be considered.

Path formatting rules

Whitespaces (space, tab character) can be used in bracket notation segments and expressions, for example: `$['a'][0][?($.b == 'c')][: -1].first()`.

Strings should be enclosed with single (') or double (") quotes. Inside the strings, single or double quotes (depending on which are used to enclose it) and backslashes (\) are escaped with the backslash (\) character.

Example

```
{

| JSONPath | Type | Result |
|--|------------|--|
| <code>\$.services..price</code> | indefinite | [154.99, 5, 46, 24.5, 99.49] |
| <code>\$.books[?(@.id == 4 - 0.4 * 5)].title</code> | indefinite | ["Sword of Honour"] |
| | | Note: This query shows that arithmetical operations can be used in queries; it can be simplified to <code>\$.books[?(@.id == 2)].title</code> |
| <code>\$.books[?(@.id == 2 \\ @.id == 4)].title</code> | indefinite | ["Sword of Honour", "The Lord of the Rings"] |
| <code>\$.books[?(!@.id == 2)].title</code> | indefinite | ["Sayings of the Century", "Moby Dick", "The Lord of the Rings"] |
| <code>\$.books[?(@.id != 2)].title</code> | indefinite | ["Sayings of the Century", "Moby Dick", "The Lord of the Rings"] |
| <code>\$.books[?(@.title =~ " of ")].title</code> | indefinite | ["Sayings of the Century", "Sword of Honour", "The Lord of the Rings"] |
| <code>\$.books[?(@.price > 12.99)].title</code> | indefinite | ["The Lord of the Rings"] |
| <code>\$.books[?(@.author > "Herman Melville")].title</code> | indefinite | ["Sayings of the Century", "The Lord of the Rings"] |
| <code>\$.books[?(@.price > \$.filters.price)].title</code> | indefinite | ["Sword of Honour", "The Lord of the Rings"] |
| <code>\$.books[?(@.category == \$.filters.category)].title</code> | indefinite | ["Sword of Honour", "Moby Dick", "The Lord of the Rings"] |
| <code>\$.books[?(@.category == "fiction" && @.price < 10)].title</code> | indefinite | ["Moby Dick"] |
| <code>\$..[?(@.id)]</code> | indefinite | [{ "price": 8.95, "id": 1, "category": "reference", "author": "Nigel Rees", "title": "Sayings of the Century" }, { "price": 12.99, "id": 2, "category": "fiction", "author": "Evelyn Waugh", "title": "Sword of Honour" }, { "price": 8.99, "id": 3, "category": "fiction", "author": "Herman Melville", "title": "Moby Dick", "isbn": "0-553-21311-3" }, { "price": 22.99, "id": 4, "category": "fiction", "author": "J. R. R. Tolkien", "title": "The Lord of the Rings", "isbn": "0-395-19395-8" }] |
| <code>\$.services..[?(@.price > 50)].description</code> | indefinite | ["Printing and assembling book in A5 format", "Rebinding torn book"] |
| <code>\$..id.length()</code> | definite | 4 |
| <code>\$.books[?(@.id == 2)].title.first()</code> | definite | Sword of Honour |

| JSONPath | Type | Result |
|---|------------|--|
| <code>\$.tags.first().length()</code> | definite | 5 |
| | | Note: <code>\$.tags</code> is an indefinite path, so it returns an array of matched elements, i.e., <code>[["a", "b", "c", "d", "e"]]</code> ; <code>first()</code> returns the first element, i.e., <code>[["a", "b", "c", "d", "e"]]</code> ; <code>length()</code> calculates the length of the element, i.e., 5. |
| <code>\$.books[*].price.min()</code> | definite | 8.95 |
| <code>\$.price.max()</code> | definite | 154.99 |
| <code>\$.books[?(@.category == "fiction")].price.avg()</code> | definite | 14.99 |
| <code>\$.books[?(@.category == \$.filters.xyz)].title</code> | indefinite | Note: A query without match returns NULL for definite and indefinite paths. |
| <code>\$.services[?(@.active=="true")].servicegroup</code> | definite | 1001,1000 |
| | | Note: Text constants must be used in boolean value comparisons. |
| <code>\$.services[?(@.active=="false")].servicegroup</code> | definite | 1002 |
| | | Note: Text constants must be used in boolean value comparisons. |
| <code>\$.services[?(@.servicegroup=="1002")].first()</code> | definite | 1002 |

1 Escaping special characters from LLD macro values in JSONPath

When low-level discovery macros are used in JSONPath preprocessing and their values are resolved, the following rules of escaping special characters are applied:

- only backslash (\) and double quote (") characters are considered for escaping;
- if the resolved macro value contains these characters, each of them is escaped with a backslash;
- if they are already escaped with a backslash, it is not considered as escaping and both the backslash and the following special characters are escaped once again.

For example:

| JSONPath | LLD macro value | After substitution |
|--|-----------------|---|
| <code>\$.[?(@.value == "{#MACRO}")]</code> | special "value" | <code>\$.[?(@.value == "special \"value\"")]</code> |
| | c:\temp | <code>\$.[?(@.value == "c:\\temp")]</code> |
| | a\\b | <code>\$.[?(@.value == "a\\\\b")]</code> |

When used in the expression, the macro that may have special characters should be enclosed in double quotes:

| JSONPath | LLD macro value | After substitution | Result |
|--|-----------------|---|--------------------------------|
| <code>\$.[?(@.value == "{#MACRO}")]</code> | special "value" | <code>\$.[?(@.value == "special \"value\"")]</code> | OK |
| <code>\$.[?(@.value == {#MACRO})]</code> | | <code>\$.[?(@.value == special \"value\"")]</code> | Bad JSONPath expression |

When used in the path, the macro that may have special characters should be enclosed in square brackets **and** double quotes:

| JSONPath | LLD macro value | After substitution | Result |
|------------------------------------|-----------------|------------------------------------|--------------------------------|
| <code>\$.["{#MACRO}"].value</code> | c:\temp | <code>\$.["c:\\temp"].value</code> | OK |
| <code>\$.{#MACRO}.value</code> | | <code>\$.c:\\temp.value</code> | Bad JSONPath expression |

5 JavaScript preprocessing

Overview

This section provides details of preprocessing by JavaScript.

JavaScript preprocessing

JavaScript preprocessing is done by invoking JavaScript function with a single parameter 'value' and user-provided function body. The preprocessing step result is the value returned by this function, for example, to perform Fahrenheit to Celsius conversion, enter:

```
return (value - 32) * 5 / 9
```

in JavaScript preprocessing parameters, which will be wrapped into a JavaScript function by server:

```
function (value)
{
    return (value - 32) * 5 / 9
}
```

The input parameter 'value' is always passed as a string. The return value is automatically coerced to string via toString() method (if it fails, then the error is returned as string value), with a few exceptions:

- returning undefined value will result in an error;
- returning null value will cause the input value to be discarded, much like 'Discard value' preprocessing on 'Custom on fail' action.

Errors can be returned by throwing values/objects (normally either strings or Error objects).

For example:

```
if (value == 0)
    throw "Zero input value"
return 1/value
```

Each script has a 10-second execution timeout (depending on the script, it might take longer for the timeout to trigger); exceeding it will return error. A 512-megabyte heap limit is enforced.

The JavaScript preprocessing step bytecode is cached and reused when the step is applied next time. Any changes to the item's preprocessing steps will cause the cached script to be reset and recompiled later.

Consecutive runtime failures (3 in a row) will cause the engine to be reinitialized to mitigate the possibility of one script breaking the execution environment for the next scripts (this action is logged with DebugLevel 4 and higher).

JavaScript preprocessing is implemented with [Duktape](#) JavaScript engine.

See also: [Additional JavaScript objects and global functions](#)

Using macros in scripts

It is possible to use user macros in JavaScript code. If a script contains user macros, these macros are resolved by server/proxy before executing specific preprocessing steps. Note that when testing preprocessing steps in the frontend, macro values will not be pulled and need to be entered manually.

Note:

Context is ignored when a macro is replaced with its value. Macro value is inserted in the code as is, it is not possible to add additional escaping before placing the value in the JavaScript code. Please be advised that this can cause JavaScript errors in some cases.

In an example below, if received value exceeds a {\$THRESHOLD} macro value, the threshold value (if present) will be returned instead:

```
var threshold = '{$THRESHOLD}';
return (!isNaN(threshold) && value > threshold) ? threshold : value;
```

Examples

The following examples illustrate how you can use JavaScript preprocessing.

Each example contains a brief description, a function body for JavaScript preprocessing parameters, and the preprocessing step result - value returned by the function.

Example 1: Convert a number (scientific notation to integer)

Convert the number "2.62128e+07" from scientific notation to an integer.

```
return (Number(value))
```

Value returned by the function: 26212800.

Example 2: Convert a number (binary to decimal)

Convert the binary number "11010010" to a decimal number.

```
return(parseInt(value,2))
```

Value returned by the function: 210.

Example 3: Round a number

Round the number "18.2345" to 2 digits.

```
return(Math.round(value* 100) / 100)
```

Value returned by the function: 18.23.

Example 4: Count letters in a string

Count the number of letters in the string "Zabbix".

```
return (value.length)
```

Value returned by the function: 6.

Example 5: Get time remaining

Get the remaining time (in seconds) until the expiration date of a certificate (Feb 12 12:33:56 2022 GMT).

```
var split = value.split(' '),
    MONTHS_LIST = ['Jan', 'Feb', 'Mar', 'Apr', 'May', 'Jun', 'Jul', 'Aug', 'Sep', 'Oct', 'Nov', 'Dec'],
    month_index = ('0' + (MONTHS_LIST.indexOf(split[0]) + 1)).slice(-2),
    ISOdate = split[3] + '-' + month_index + '-' + split[1] + 'T' + split[2],
    now = Date.now();

return parseInt((Date.parse(ISOdate) - now) / 1000);
```

Value returned by the function: 44380233.

Example 6: Remove JSON properties

Modify the JSON data structure by removing any properties with the key "data_size" or "index_size".

```
var obj=JSON.parse(value);

for (i = 0; i < Object.keys(obj).length; i++) {
    delete obj[i]["data_size"];
    delete obj[i]["index_size"];
}

return JSON.stringify(obj)
```

Value accepted by the function:

```
[
  {
    "table_name": "history",
    "data_size": "326.05",
    "index_size": "174.34"
  },
  {
    "table_name": "history_log",
    "data_size": "6.02",
    "index_size": "3.45"
  }
]
```

Value returned by the function:

```
[
  {
    "table_name": "history"
  },
  {
    "table_name": "history_log"
  }
]
```

Example 7: Convert Apache status to JSON

Convert the value received from a `web.page.get` Zabbix agent item (e.g., `web.page.get[http://127.0.0.1:80/server-status?auto]`) to a JSON object.

```
// Convert Apache status to JSON

// Split the value into substrings and put these substrings into an array
var lines = value.split('\n');

// Create an empty object "output"
var output = {};

// Create an object "workers" with predefined properties
var workers = {
  '_': 0, 'S': 0, 'R': 0, 'W': 0,
  'K': 0, 'D': 0, 'C': 0, 'L': 0,
  'G': 0, 'I': 0, '.': 0
};

// Add the substrings from the "lines" array to the "output" object as properties (key-value pairs)
for (var i = 0; i < lines.length; i++) {
  var line = lines[i].match(/([A-z0-9 ]+): (.*)/);

  if (line !== null) {
    output[line[1]] = isNaN(line[2]) ? line[2] : Number(line[2]);
  }
}

// Multiversion metrics
output.ServerUptimeSeconds = output.ServerUptimeSeconds || output.Uptime;
output.ServerVersion = output.ServerVersion || output.Server;

// Parse "Scoreboard" property to get the worker count
if (typeof output.Scoreboard === 'string') {
  for (var i = 0; i < output.Scoreboard.length; i++) {
    var char = output.Scoreboard[i];

    workers[char]++;
  }
}

// Add worker data to the "output" object
output.Workers = {
  waiting: workers['_'], starting: workers['S'], reading: workers['R'],
  sending: workers['W'], keepalive: workers['K'], dnslookup: workers['D'],
  closing: workers['C'], logging: workers['L'], finishing: workers['G'],
  cleanup: workers['I'], slot: workers['.']
};

// Return JSON string
return JSON.stringify(output);
```

Value accepted by the function:

HTTP/1.1 200 OK

Date: Mon, 27 Mar 2023 11:08:39 GMT

1 Additional JavaScript objects

Overview

This section describes Zabbix additions to the JavaScript language implemented with Duktape, and supported **global JavaScript functions**.

Built-in objects

Zabbix

The Zabbix object provides interaction with the internal Zabbix functionality.

| Method | Description |
|------------------------|--|
| log(loglevel, message) | Writes <message> into Zabbix log using <loglevel> log level (see configuration file DebugLevel parameter). |

Example:

```
Zabbix.log(3, "this is a log entry written with 'Warning' log level")
```

You may use the following aliases:

| Alias | Alias to |
|-----------------------|---------------------------------------|
| console.log(object) | Zabbix.log(4, JSON.stringify(object)) |
| console.warn(object) | Zabbix.log(3, JSON.stringify(object)) |
| console.error(object) | Zabbix.log(2, JSON.stringify(object)) |

Attention:

The total size of all logged messages is limited to 8 MB per script execution.

| Method | Description |
|--------------|---|
| sleep(delay) | Delay JavaScript execution by delay milliseconds. |

Example (delay execution by 15 seconds):

Zabbix.sleep(15000)

HttpRequest

This object encapsulates cURL handle allowing to make simple HTTP requests. Errors are thrown as exceptions.

Attention:

The initialization of multiple `HttpRequest` objects is limited to 10 per script execution.

| Method | Description |
|---|--|
| <code>addHeader(value)</code> | Adds HTTP header field. This field is used for all following requests until cleared with the <code>clearHeader()</code> method. The total length of header fields that can be added to a single <code>HttpRequest</code> object is limited to 128 Kbytes (special characters and header names included). |
| <code>clearHeader()</code> | Clears HTTP header. If no header fields are set, <code>HttpRequest</code> will set Content-Type to application/json if the data being posted is JSON-formatted; text/plain otherwise. |
| <code>connect(url)</code> | Sends HTTP CONNECT request to the URL and returns the response. |
| <code>customRequest(method, url, data)</code> | Allows to specify any HTTP method in the first parameter. Sends the method request to the URL with optional <i>data</i> payload and returns the response. |
| <code>delete(url, data)</code> | Sends HTTP DELETE request to the URL with optional <i>data</i> payload and returns the response. |
| <code>getHeaders(<asArray>)</code> | Returns the object of received HTTP header fields. The <i>asArray</i> parameter may be set to "true" (e.g., <code>getHeaders(true)</code>), "false" or be undefined. If set to "true", the received HTTP header field values will be returned as arrays; this should be used to retrieve the field values of multiple same-name headers. If not set or set to "false", the received HTTP header field values will be returned as strings. |
| <code>get(url, data)</code> | Sends HTTP GET request to the URL with optional <i>data</i> payload and returns the response. |
| <code>head(url)</code> | Sends HTTP HEAD request to the URL and returns the response. |
| <code>options(url)</code> | Sends HTTP OPTIONS request to the URL and returns the response. |
| <code>patch(url, data)</code> | Sends HTTP PATCH request to the URL with optional <i>data</i> payload and returns the response. |
| <code>put(url, data)</code> | Sends HTTP PUT request to the URL with optional <i>data</i> payload and returns the response. |
| <code>post(url, data)</code> | Sends HTTP POST request to the URL with optional <i>data</i> payload and returns the response. |
| <code>getStatus()</code> | Returns the status code of the last HTTP request. |
| <code>setProxy(proxy)</code> | Sets HTTP proxy to "proxy" value. If this parameter is empty, then no proxy is used. |
| <code>setHttpAuth(bitmask, username, password)</code> | Sets enabled HTTP authentication methods (HTTPAUTH_BASIC, HTTPAUTH_DIGEST, HTTPAUTH_NEGOTIATE, HTTPAUTH_NTLM, HTTPAUTH_NONE) in the 'bitmask' parameter. The HTTPAUTH_NONE flag allows to disable HTTP authentication. Examples: <code>request.setHttpAuth(HTTPAUTH_NTLM HTTPAUTH_BASIC, username, password)</code> <code>request.setHttpAuth(HTTPAUTH_NONE)</code> |
| <code>trace(url, data)</code> | Sends HTTP TRACE request to the URL with optional <i>data</i> payload and returns the response. |

Example:

```
try {
    Zabbix.log(4, 'jira webhook script value='+value);

    var result = {
        'tags': {
            'endpoint': 'jira'
        }
    },
    params = JSON.parse(value),
    req = new HttpRequest(),
    fields = {},
    resp;

    req.addHeader('Content-Type: application/json');
    req.addHeader('Authorization: Basic '+params.authentication);

    fields.summary = params.summary;
    fields.description = params.description;
    fields.project = {"key": params.project_key};
}
```

```

fields.issueType = {"id": params.issue_id};
resp = req.post('https://jira.example.com/rest/api/2/issue/',
    JSON.stringify({"fields": fields})
);

if (req.getStatus() != 201) {
    throw 'Response code: '+req.getStatus();
}

resp = JSON.parse(resp);
result.tags.issue_id = resp.id;
result.tags.issue_key = resp.key;
} catch (error) {
    Zabbix.log(4, 'jira issue creation failed json : '+JSON.stringify({"fields": fields}));
    Zabbix.log(4, 'jira issue creation failed : '+error);

    result = {};
}

return JSON.stringify(result);

```

XML

The XML object allows the processing of XML data in the item and low-level discovery preprocessing and webhooks.

Attention:

In order to use XML object, server/proxy must be compiled with libxml2 support.

| Method | Description |
|-----------------------------|---|
| XML.query(data, expression) | Retrieves node content using XPath. Returns null if node is not found. expression - an XPath expression; data - XML data as a string. |
| XML.toJson(data) | Converts data in XML format to JSON. |
| XML.fromJson(object) | Converts data in JSON format to XML. |

Example:

Input:

```

<menu>
  <food type = "breakfast">
    <name>Chocolate</name>
    <price>$5.95</price>
    <description></description>
    <calories>650</calories>
  </food>
</menu>

```

Output:

```

{
  "menu": {
    "food": {
      "@type": "breakfast",
      "name": "Chocolate",
      "price": "$5.95",
      "description": null,
      "calories": "650"
    }
  }
}

```

Serialization rules

XML to JSON conversion will be processed according to the following rules (for JSON to XML conversions reversed rules are applied):

1. XML attributes will be converted to keys that have their names prepended with '@'.

Example:

Input:

```
<xml foo="F00">
  <bar>
    <baz>BAZ</baz>
  </bar>
</xml>
```

Output:

```
{
  "xml": {
    "@foo": "F00",
    "bar": {
      "baz": "BAZ"
    }
  }
}
```

2. Self-closing elements (<foo/>) will be converted as having 'null' value.

Example:

Input:

```
<xml>
  <foo/>
</xml>
```

Output:

```
{
  "xml": {
    "foo": null
  }
}
```

3. Empty attributes (with "" value) will be converted as having empty string (") value.

Example:

Input:

```
<xml>
  <foo bar="" />
</xml>
```

Output:

```
{
  "xml": {
    "foo": {
      "@bar": ""
    }
  }
}
```

4. Multiple child nodes with the same element name will be converted to a single key that has an array of values as its value.

Example:

Input:

```
<xml>
  <foo>BAR</foo>
  <foo>BAZ</foo>
  <foo>QUX</foo>
</xml>
```

Output:

```
{
  "xml": {
    "foo": ["BAR", "BAZ", "QUX"]
  }
}
```

5. If a text element has no attributes and no children, it will be converted as a string.

Example:

Input:

```
<xml>
  <foo>BAZ</foo>
</xml>
```

Output:

```
{
  "xml": {
    "foo": "BAZ"
  }
}
```

6. If a text element has no children but has attributes, text content will be converted to an element with the key '#text' and content as a value; attributes will be converted as described in the serialization rule 1.

Example:

Input:

```
<xml>
  <foo bar="BAR">
    BAZ
  </foo>
</xml>
```

Output:

```
{
  "xml": {
    "foo": {
      "@bar": "BAR",
      "#text": "BAZ"
    }
  }
}
```

Global JavaScript functions

Additional global JavaScript functions have been implemented with Duktape:

- btoa(data) - encodes the data to base64 string;
- atob(base64_string) - decodes base64 string as Uint8Array buffer.

```
try {
  b64 = btoa("test string");
  buffer = atob(b64);

  // Note that decoding logic depends on the data format of the buffer.
  decoded = String.fromCharCode.apply(this, [].slice.call(buffer));
}
catch (error) {
  return {'error.name' : error.name, 'error.message' : error.message};
}
```

- md5(data) - calculates the MD5 hash of the data
- sha256(data) - calculates the SHA256 hash of the data

- `hmac('<hash type>',key,data)` - returns HMAC hash as hex formatted string; MD5 and SHA256 hash types are supported; key and data parameters support binary data. Examples:
 - `hmac('md5',key,data)`
 - `hmac('sha256',key,data)`
- `sign(hash,key,data)` - returns calculated signature (RSA signature with SHA-256) as a string, where:
 - **hash** - only 'sha256' is allowed, otherwise an error is thrown;
 - **key** - the private key. It should correspond to PKCS#1 or PKCS#8 standard. The key can be provided in different forms:
 - with spaces instead of newlines;
 - with escaped or non-escaped `\n` instead of newlines;
 - without any newlines as a single-line string;
 - as a JSON-formatted string.

The key also can be loaded from a user macro/secret macro/vault.

data - the data that will be signed. It can be a string (binary data also supported) or buffer (Uint8Array/ArrayBuffer).
 OpenSSL or GnuTLS is used to calculate the signatures. If Zabbix was built without any of these encryption libraries, an error will be thrown ('missing OpenSSL or GnuTLS library').

2 Browser item JavaScript objects

Overview

This section describes Zabbix additions to the JavaScript language implemented with Duktape for use in the **Browser item** script. These additions supplement the JavaScript objects described on the **Additional JavaScript objects** page.

Browser

The Browser object manages WebDriver sessions, initializing a session upon creation and terminating it upon destruction. A single script can support up to four Browser objects.

To construct a Browser object, use the `new Browser(options)` syntax. The `options (JSON object)` parameter specifies browser options, usually the WebDriver options method result (for example, `Browser.chromeOptions()`).

The following methods are supported with the Browser object.

| Method | Description |
|--|--|
| <code>navigate(url)</code> | Navigate to the specified URL. |
| <code>getUrl()</code> | Parameters: <code>url</code> - (string) URL to navigate to. |
| <code>getPageSource()</code> | Return a string of the opened page URL. |
| <code>findElement(strategy, selector)</code> | Return a string of the opened page source. Return an Element object with one element in the opened page (or return null if no elements match strategy and selector). |
| <code>findElements(strategy, target)</code> | Parameters: <code>strategy</code> - (string, CSS selector/link text/partial link text/tag name/Xpath) Location strategy; <code>selector</code> - (string) Element selector using the specified location strategy. Return an array of Element objects with multiple elements in the opened page (or return an empty array if no elements match location strategy and target). |
| <code>getCookies()</code> | Parameters: <code>strategy</code> - (string, CSS selector/link text/partial link text/tag name/Xpath) Location strategy; |
| <code>addCookie(cookie)</code> | <code>target</code> - (string) Element selector using the specified location strategy. Return an array of Cookie objects. Set cookies. |
| <code>getScreenshot()</code> | Parameters: <code>cookie</code> - (Cookie object) Cookie to set. Return a base64 encoded string representing an image of the browser's viewport. |

| Method | Description |
|---|---|
| <code>setSize(x,y)</code> | Set the browser's viewport size. |
| | Parameters: x - (string) Height in pixels; y - (string) Width in pixels. |
| <code>setTimeout(timeout)</code> | Set script loading timeout. |
| | Parameters: timeout - (integer) Timeout value in milliseconds. |
| <code>setSessionTimeout(timeout)</code> | Set session (page load) timeout. |
| | Parameters: timeout - (integer) Timeout value in milliseconds. |
| <code>setElementWaitTimeout(timeout)</code> | Set element location strategy (implicit) timeout. |
| | Parameters: timeout - (integer) Timeout value in milliseconds. |
| <code>collectPerfEntries(mark)</code> | Collect performance entries to retrieve with the <code>getResult()</code> method. |
| | Parameters: mark - (string, optional) performance snapshot mark. |
| <code>getRawPerfEntries()</code> | Return an array of performance entry objects. |
| <code>getResult()</code> | Return a Result object with browser session statistics (error information, performance snapshots, etc.). |
| <code>getError()</code> | Return a BrowserError object with browser errors (or return null if there are no browser errors). |
| <code>setError(message)</code> | Set a custom error message to be included in the Result object. |
| | Parameters: message - (string) Error message. |
| <code>discardError()</code> | Discard the error to be returned in the Result object. |
| <code>getAlert()</code> | Return an Alert object with browser alerts (or return null if there are no browser alerts). |
| <code>chromeOptions()</code> | Return a chromeOptions object with predefined Chrome browser options. |
| <code>firefoxOptions()</code> | Return a firefoxOptions object with predefined Firefox browser options. |
| <code>safariOptions()</code> | Return a safariOptions object with predefined Safari browser options. |
| <code>edgeOptions()</code> | Return an edgeOptions object with predefined Edge browser options. |
| <code>switchFrame(target)</code> | Switch to the specified frame. |
| | Parameters: target - (browser element or integer, optional) Target frame. To select a frame by element, pass the element. To select a frame by index, pass the number. If left empty, will switch to the top-level browsing context. |

All Browser methods can throw the following errors:

- **BrowserError** - derived from the **Error** object that is thrown if the **Browser** constructor fails; contains an additional **browser** property with a **Browser** object that threw this **BrowserError**.
- **WebdriverError** - derived from **BrowserError**; contains the same properties as the **BrowserError** object, which indicate if the error was generated in response to an error in the **WebDriver** response.

Element

The **Element** object is returned by the **Browser** object `findElement()/findElements()` methods and cannot be constructed directly.

The **Element** object represents an element in the web page and provides methods to interact with it.

The following methods are supported with the **Element** object.

| Method | Description |
|---------------------------------|--|
| <code>getAttribute(name)</code> | Return an attribute value string of the element attribute (or return null if the specified attribute was not found). |
| <code>getProperty(name)</code> | Parameters: name - (string) Attribute name. Return a property value string of the element property (or return null if the specified property was not found). |
| <code>getText()</code> | Return a text value string of the element text. |
| <code>click()</code> | Click on an element. |
| <code>clear()</code> | Clear the content of an editable element. |
| <code>sendKeys(keys)</code> | Send keys. |
| | Parameters: keys - (string) Keys to send. |

Cookie

The Cookie object is returned by the **Browser** object `getCookies()` method and passed to the `addCookie()` method.

While the Cookie object does not have any methods, it can contain the following properties:

| Property | Type | Description |
|----------|---------|---|
| name | string | Name of the cookie. |
| value | string | Value of the cookie. |
| path | string | Path for which the cookie is valid. Defaults to "/" if omitted when adding a cookie. |
| domain | string | Domain to which the cookie is visible. Defaults to the URL domain of the session's current browsing context's active document if omitted when adding a cookie. |
| secure | boolean | Indicates whether the cookie is secure. Defaults to false if omitted when adding a cookie. |
| httpOnly | boolean | Indicates whether the cookie is HTTP-only. Defaults to false if omitted when adding a cookie. |
| expiry | integer | Expiration time of the cookie (in seconds since the Unix Epoch). Must not be set if omitted when adding a cookie. |
| sameSite | string | The sameSite attribute of the cookie, which controls whether the cookie should be restricted to a first-party or same-site context. Can be set to either "Lax" or "Strict". Defaults to "None" if omitted when adding a cookie. |

Alert

The Alert object represents a web page alert, is returned by **Browser** object `getAlert()` method, and cannot be constructed directly.

The Alert object contains the text property with the alert text (or null if there are no alerts).

The following methods are supported with the Alert object.

| Method | Description |
|------------------------|--------------------|
| <code>accept()</code> | Accept the alert. |
| <code>dismiss()</code> | Dismiss the alert. |

Result

The Result object contains session statistics and is returned by the **Browser** object `getResult()` method.

Typically, the Result object is stringified and returned from the script, and then parsed into dependent item values through preprocessing.

While the `Result` object does not have any methods, it can contain the following properties.

| Property | Type | Description |
|-------------------------------|------------------|---|
| <code>duration</code> | string | Session duration from session creation to result retrieval. |
| <code>error</code> | object | Error information. |
| <code>http_status</code> | integer | HTTP status returned by the WebDriver (or 0 if there are no WebDriver errors). |
| <code>error_code</code> | string | Error returned by the WebDriver (or empty string if there are no WebDriver errors). |
| <code>message</code> | string | WebDriver error message (or empty string if there are no WebDriver errors). |
| <code>performance_data</code> | object | Performance statistics. |
| <code>summary</code> | object | Performance summary. |
| <code>navigator</code> | object | Navigation summary. |
| <code>resources</code> | object | Resource summary. |
| <code>details</code> | array of objects | Performance statistics after each operation that could have resulted in navigation. |
| <code>mark</code> | string | (optional) Performance snapshot mark specified with the <code>collectPerfEntries()</code> method. |
| <code>navigator</code> | object | Navigation statistics. |
| <code>resources</code> | object | Resource summary for this step. |
| <code>user</code> | array of objects | Array of mark/measure type statistics. |
| <code>marks</code> | array of objects | Marked performance snapshot indexes. |
| <code>name</code> | string | Performance snapshot mark name. |
| <code>index</code> | integer | Performance snapshot index in details array. |

6 CSV to JSON preprocessing

Overview

In this preprocessing step it is possible to convert CSV file data into JSON format. It's supported in:

- items (item prototypes)
- low-level discovery rules

Configuration

To configure a CSV to JSON preprocessing step:

- Go to the Preprocessing tab in **item/discovery rule** configuration
- Click on **Add**
- Select the **CSV to JSON** option

The first parameter allows to set a custom delimiter. Note that if the first line of CSV input starts with "Sep=" and is followed by a single UTF-8 character then that character will be used as the delimiter in case the first parameter is not set. If the first parameter is not set and a delimiter is not retrieved from the "Sep=" line, then a comma is used as a separator.

The second optional parameter allows to set a quotation symbol.

If the *With header row* checkbox is marked, the header line values will be interpreted as column names (see **Header processing** for more information).

If the *Custom on fail* checkbox is marked, the item will not become unsupported in case of a failed preprocessing step. Additionally, custom error handling options may be set: discard the value, set a specified value or set a specified error message.

Header processing

The CSV file header line can be processed in two different ways:

- If the *With header row* checkbox is marked - header line values are interpreted as column names. In this case the column names must be unique and the data row should not contain more columns than the header row.
- If the *With header row* checkbox is not marked - the header line is interpreted as data. Column names are generated automatically (1,2,3,4...).

CSV file example:

```
Nr,Item name,Key,Qty
1,active agent item,agent.hostname,33
"2","passive agent item","agent.version","44"
3,"active,passive agent items",agent.ping,55
```

Note:

A quotation character within a quoted field in the input must be escaped by preceding it with another quotation character.

Processing header line

JSON output when a header line is expected:

```
[
  {
    "Nr": "1",
    "Item name": "active agent item",
    "Key": "agent.hostname",
    "Qty": "33"
  },
  {
    "Nr": "2",
    "Item name": "passive agent item",
    "Key": "agent.version",
    "Qty": "44"
  },
  {
    "Nr": "3",
    "Item name": "active,passive agent items",
    "Key": "agent.ping",
    "Qty": "55"
  }
]
```

No header line processing

JSON output when a header line is not expected:

```
[
  {
    "1": "Nr",
    "2": "Item name",
    "3": "Key",
    "4": "Qty"
  },
  {
    "1": "1",
    "2": "active agent item",
    "3": "agent.hostname",
    "4": "33"
  },
  {
    "1": "2",
    "2": "passive agent item",
    "3": "agent.version",
    "4": "44"
  },
  {

```

```
    "1": "3",
    "2": "active,passive agent items",
    "3": "agent.ping",
    "4": "55"
  }
]
```

3 Item types

Overview

Item types cover various methods of acquiring data from your system. Each item type comes with its own set of supported item keys and required parameters.

The following items types are currently offered by Zabbix:

- Zabbix agent checks
- SNMP agent checks
- SNMP traps
- IPMI checks
- Simple checks
 - VMware monitoring
- Log file monitoring
- Calculated items
 - Aggregate calculations
- Zabbix internal checks
- SSH checks
- Telnet checks
- External checks
- Trapper items
- JMX monitoring
- ODBC checks
- Dependent items
- HTTP checks
- Prometheus checks
- Script items
- Browser items

Details for all item types are included in the subpages of this section. Even though item types offer a lot of options for data gathering, there are further options through [user parameters](#) or [loadable modules](#).

Some checks are performed by Zabbix server alone (as agent-less monitoring) while others require Zabbix agent or even Zabbix Java gateway (with JMX monitoring).

Attention:

If a particular item type requires a particular interface (like an IPMI check needs an IPMI interface on the host) that interface must exist in the host definition.

Multiple interfaces can be set in the host definition: Zabbix agent, SNMP agent, JMX and IPMI. If an item can use more than one interface, it will search the available host interfaces (in the order: Agent→SNMP→JMX→IPMI) for the first appropriate one to be linked with.

All items that return text (character, log, text types of information) can return whitespace only as well (where applicable) setting the return value to an empty string (supported since 2.0).

1 Zabbix agent

Overview

This section provides details on the item keys that use communication with Zabbix agent for data gathering.

There are [passive](#) and [active](#) agent checks. When configuring an item, you can select the required type:

- *Zabbix agent* - for passive checks
- *Zabbix agent (active)* - for active checks

Note that all item keys supported by Zabbix agent on Windows are also supported by the new generation Zabbix agent 2. See the [additional item keys](#) that you can use with the agent 2 only.

Supported item keys

The item keys that you can use with Zabbix agent are listed below.

The item keys are listed without parameters and additional information. Click on the item key to see the full details.

| Item key | Description | Item group |
|--|---|----------------|
| kernel.maxfiles | The maximum number of opened files supported by OS. | Kernel |
| kernel.maxproc | The maximum number of processes supported by OS. | |
| kernel.openfiles | The number of currently open file descriptors. | |
| log | The monitoring of a log file. | |
| log.count | The count of matched lines in a monitored log file. | Log monitoring |
| logrt | The monitoring of a log file that is rotated. | |
| logrt.count | The count of matched lines in a monitored log file that is rotated. | |
| modbus.get | Reads Modbus data. | |
| net.dns | Checks the status of a DNS service. | Modbus Network |
| net.dns.perf | Checks the performance of a DNS service. | |
| net.dns.record | Performs a DNS query. | |
| net.if.collisions | The number of out-of-window collisions. | |
| net.if.discovery | The list of network interfaces. | |
| net.if.in | The incoming traffic statistics on a network interface. | |
| net.if.out | The outgoing traffic statistics on a network interface. | |
| net.if.total | The sum of incoming and outgoing traffic statistics on a network interface. | |
| net.tcp.listen | Checks if this TCP port is in LISTEN state. | |
| net.tcp.port | Checks if it is possible to make a TCP connection to the specified port. | |
| net.tcp.service | Checks if a service is running and accepting TCP connections. | |
| net.tcp.service.perf | Checks the performance of a TCP service. | |
| net.tcp.socket.count | Returns the number of TCP sockets that match parameters. | |
| net.udp.listen | Checks if this UDP port is in LISTEN state. | |
| net.udp.service | Checks if a service is running and responding to UDP requests. | |
| net.udp.service.perf | Checks the performance of a UDP service. | |
| net.udp.socket.count | Returns the number of UDP sockets that match parameters. | Processes |
| proc.cpu.util | The process CPU utilization percentage. | |
| proc.get | The list of OS processes and their parameters. | |
| proc.mem | The memory used by the process in bytes. | |
| proc.num | The number of processes. | |
| sensor | Hardware sensor reading. | |
| system.boottime | The system boot time. | |
| system.cpu.discovery | The list of detected CPUs/CPU cores. | |
| system.cpu.intr | The device interrupts. | |
| system.cpu.load | The CPU load. | |
| system.cpu.num | The number of CPUs. | |
| system.cpu.switches | The count of context switches. | |
| system.cpu.util | The CPU utilization percentage. | |
| system.hostname | The system host name. | |
| system.hw.chassis | The chassis information. | |
| system.hw.cpu | The CPU information. | |
| system.hw.devices | The listing of PCI or USB devices. | |
| system.hw.macaddr | The listing of MAC addresses. | |
| system.localtime | The system time. | |
| system.run | Run the specified command on the host. | |
| system.stat | The system statistics. | |
| system.sw.arch | The software architecture information. | |
| system.sw.os | The operating system information. | |
| system.sw.os.get | Detailed information about the operating system (version, type, distribution name, minor and major version, etc). | |
| system.sw.packages | The listing of installed packages. | |
| system.sw.packages.get | A detailed listing of installed packages. | |
| system.swap.in | The swap-in (from device into memory) statistics. | |
| system.swap.out | The swap-out (from memory onto device) statistics. | |

| Item key | Description | Item group |
|--------------------------------------|--|----------------------------------|
| system.swap.size | The swap space size in bytes or in percentage from total. | Virtual file systems |
| system.uname | Identification of the system. | |
| system.uptime | The system uptime in seconds. | |
| system.users.num | The number of users logged in. | |
| vfs.dev.discovery | The list of block devices and their type. | |
| vfs.dev.read | The disk read statistics. | |
| vfs.dev.write | The disk write statistics. | |
| vfs.dir.count | The directory entry count. | |
| vfs.dir.get | The directory entry list. | |
| vfs.dir.size | The directory size. | |
| vfs.file.cksum | The file checksum, calculated by the UNIX cksum algorithm. | |
| vfs.file.contents | Retrieving the contents of a file. | |
| vfs.file.exists | Checks if the file exists. | |
| vfs.file.get | Returns information about a file. | |
| vfs.file.md5sum | The MD5 checksum of file. | |
| vfs.file.owner | Retrieves the owner of a file. | Virtual memory Web monitoring |
| vfs.file.permissions | Returns a 4-digit string containing the octal number with UNIX permissions. | |
| vfs.file.regexp | Retrieve a string in the file. | |
| vfs.file.regmatch | Find a string in the file. | |
| vfs.file.size | The file size. | |
| vfs.file.time | The file time information. | |
| vfs.fs.discovery | The list of mounted filesystems with their type and mount options. | |
| vfs.fs.get | The list of mounted filesystems with their type, available disk space, inode statistics and mount options. | |
| vfs.fs.inode | The number or percentage of inodes. | |
| vfs.fs.size | The disk space in bytes or in percentage from total. | |
| vm.memory.size | The memory size in bytes or in percentage from total. | |
| web.page.get | Get the content of a web page. | |
| web.page.perf | The loading time of a full web page. | Zabbix |
| web.page.regexp | Find a string on the web page. | |
| agent.hostmetadata | The agent host metadata. | |
| agent.hostname | The agent host name. | |
| agent.ping | The agent availability check. | |
| agent.variant | The variant of Zabbix agent (Zabbix agent or Zabbix agent 2). | |
| agent.version | The version of Zabbix agent. | |
| zabbix.stats | Returns a set of Zabbix server or proxy internal metrics remotely. | |
| zabbix.stats | Returns the number of monitored items in the queue which are delayed on Zabbix server or proxy remotely. | |

Supported platforms

Except where specified differently in the item details, the agent items (and all parameters) are supported on:

- **Linux**
- **FreeBSD**
- **Solaris**
- **HP-UX**
- **AIX**
- **MacOS X**
- **OpenBSD**
- **NetBSD**

Many agent items are also supported on **Windows**. See the [Windows agent item](#) page for details.

Item key details

Parameters without angle brackets are mandatory. Parameters marked with angle brackets < > are optional.

[kernel.maxfiles](#)

 The maximum number of opened files supported by OS.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, MacOS X, OpenBSD, NetBSD.

kernel.maxproc

 The maximum number of processes supported by OS.
 Return value: *Integer*.
 Supported platforms: Linux 2.6 and later, FreeBSD, Solaris, MacOS X, OpenBSD, NetBSD.

kernel.openfiles

 The number of currently open file descriptors.
 Return value: *Integer*.
 Supported platforms: Linux (the item may work on other UNIX-like platforms).

log[file,<regexp>,<encoding>,<maxlines>,<mode>,<output>,<maxdelay>,<options>,<persistent dir>]

 The monitoring of a log file.
 Return value: *Log*.
 See **supported platforms**.

Parameters:

- **file** - the full path and name of a log file;

- **regexp** - a regular **expression** describing the required pattern;

- **encoding** - the code page **identifier**;

- **maxlines** - the maximum number of new lines per second the agent will send to Zabbix server or proxy. This parameter overrides the value of 'MaxLinesPerSecond' in **zabbix_agentd.conf**;

- **mode** - possible values: *all* (default) or *skip* - skip processing of older data (affects only newly created items);

- **output** - an optional output formatting template. The **\0** escape sequence is replaced with the matched part of text (from the first character where match begins until the character where match ends) while an **\N** (where N=1...9) escape sequence is replaced with Nth matched group (or an empty string if the N exceeds the number of captured groups);

- **maxdelay** - the maximum delay in seconds. Type: float. Values: 0 - (default) never ignore log file lines; > 0.0 - ignore older lines in order to get the most recent lines analyzed within "maxdelay" seconds. Read the **maxdelay** notes before using it!

- **options** - additional options:
mtime-noreread - non-unique records, reread only if the file size changes (ignore modification time change). (This parameter is deprecated since 5.0.2, because now mtime is ignored.)

- **persistent dir** (only in zabbix_agentd on Unix systems; not supported in Zabbix agent 2) - the absolute pathname of directory where to store persistent files. See also additional notes on **persistent files**.

Comments:

- The item must be configured as an **active check**;
- If the file is missing or permissions do not allow access, the item turns unsupported;
- If output is left empty - the whole line containing the matched text is returned. Note that all global regular expression types except 'Result is TRUE' always return the whole matched line and the output parameter is ignored.
- Content extraction using the output parameter takes place on the agent.

Examples:

```
log[/var/log/syslog]
log[/var/log/syslog,error]
log[/home/zabbix/logs/logfile,,,100]
```

Example of using the output parameter for extracting a number from log record:

```
log[/app1/app.log,"task run [0-9.]+ sec, processed ([0-9]+) records, [0-9]+ errors",,,,1] #this item will
```

Example of using the output parameter for rewriting a log record before sending to server:

```
log[/app1/app.log,"([0-9 :-]+) task run ([0-9.]+) sec, processed ([0-9]+) records, ([0-9]+) errors",,,,1]
log.count[file,<regexp>,<encoding>,<maxproclines>,<mode>,<maxdelay>,<options>,<persistent dir>]
```

 The count of matched lines in a monitored log file.
 Return value: *Integer*.
 See **supported platforms**.

Parameters:

- **file** - the full path and name of log file;

- **regexp** - a regular **expression** describing the required pattern;

- **encoding** - the code page **identifier**;

- **maxproclines** - the maximum number of new lines per second the agent will analyze (cannot exceed 10000). The default value is 10*'MaxLinesPerSecond' in **zabbix_agentd.conf**.

- **mode** - possible values: *all* (default) or *skip* - skip processing of older data (affects only newly created items).

- **maxdelay** - the maximum delay in seconds. Type: float. Values: 0 - (default) never ignore log file lines; > 0.0 - ignore older lines in order to get the most recent lines analyzed within "maxdelay" seconds. Read the **maxdelay** notes before using it!

- **options** - additional options:
mtime-noread - non-unique records, reread only if the file size changes (ignore modification time change). (This parameter is deprecated since 5.0.2, because now *mtime* is ignored.)

- **persistent dir** (only in *zabbix_agentd* on Unix systems; not supported in Zabbix agent 2) - the absolute pathname of directory where to store persistent files. See also additional notes on [persistent files](#).

Comments:

- The item must be configured as an **active check**;
- Matching lines are counted in the new lines since the last log check by the agent, and thus depend on the item update interval;
- If the file is missing or permissions do not allow access, the item turns unsupported.

`logrt[file regexp,<regexp>,<encoding>,<maxlines>,<mode>,<output>,<maxdelay>,<options>,<persistent dir>]`

 The monitoring of a log file that is rotated.
 Return value: *Log*.
 See [supported platforms](#).

Parameters:

- **file regexp** - the absolute path to file, with the file name specified using a regular **expression**. Note that the regular expression applies only to the file name and does not need to match the entire name (e.g., `/path/to/agent` will match `zabbix_agentd.log`).

- **regexp** - a regular **expression** describing the required content pattern.

- **encoding** - the code page **identifier**.

- **maxlines** - the maximum number of new lines per second the agent will send to Zabbix server or proxy. This parameter overrides the value of 'MaxLinesPerSecond' in `zabbix_agentd.conf`.

- **mode** - possible values: *all* (default) or *skip* - skip processing of older data (affects only newly created items).

- **output** - an optional output formatting template. The `\0` escape sequence is replaced with the matched part of text (from the first character where match begins until the character where match ends) while an `\N` (where `N=1...9`) escape sequence is replaced with Nth matched group (or an empty string if the `N` exceeds the number of captured groups).

- **maxdelay** - the maximum delay in seconds. Type: float. Values: 0 - (default) never ignore log file lines; > 0.0 - ignore older lines in order to get the most recent lines analyzed within "maxdelay" seconds. Read the [maxdelay](#) notes before using it!

- **options** - the type of log file rotation and other options. Possible values:
rotate (default),
copytruncate - note that *copytruncate* cannot be used together with *maxdelay*. In this case *maxdelay* must be 0 or not specified; see [copytruncate](#) notes,
mtime-reread - non-unique records, reread if modification time or size changes (default),
mtime-noread - non-unique records, reread only if the size changes (ignore modification time change).

- **persistent dir** (only in *zabbix_agentd* on Unix systems; not supported in Zabbix agent 2) - the absolute pathname of directory where to store persistent files. See also additional notes on [persistent files](#).

Comments:

- The item must be configured as an **active check**;
- Log rotation is based on the last modification time of files;
- Note that *logrt* is designed to work with one currently active log file, with several other matching inactive files rotated. If, for example, a directory has many active log files, a separate *logrt* item should be created for each one. Otherwise if one *logrt* item picks up too many files it may lead to exhausted memory and a crash of monitoring.
- If output is left empty - the whole line containing the matched text is returned. Note that all global regular expression types except 'Result is TRUE' always return the whole matched line and the output parameter is ignored.
- Content extraction using the output parameter takes place on the agent.
- In the `file regexp` parameter, the log directory path and log file regular expression must be separated by the correct directory separator:
 - on Windows, the separator must be a backslash (`\`); forward slashes may be tolerated at other positions, except the one that separates the log directory path and the log file regular expression (see examples below).
 - on other systems, it must be a forward slash (`/`).

Examples for Windows:

```
logrt["c:/dir1/dir2/dir3\filename.*\.log","pattern_to_match"] #this item will collect data from log files
logrt["//example.com/share/dir1/dir2/dir3\filename.*\.log","pattern_to_match"] #this item will collect data
```

Examples for other systems:

```
logrt["/home/zabbix/logs/~logfile[0-9]{1,3}$",,,100] #this item will match a file like "logfile1" (will not match "logfile10")
logrt["/home/user/~logfile._.[0-9]{1,3}$","pattern_to_match","UTF-8",100] #this item will collect data from
```

Example of using the output parameter for extracting a number from log record:

```
logrt[/app1/~test.*log$,"task run [0-9.]+ sec, processed ([0-9]+) records, [0-9]+ errors",,,\1] #this item will
```

Example of using the output parameter for rewriting a log record before sending to server:

```
logrt[/app1/^test.*log$,"([0-9 :-]+) task run ([0-9.]+) sec, processed ([0-9]+) records, ([0-9]+) errors",  
logrt.count[file regexp,<regexp>,<encoding>,<maxproclines>,<mode>,<maxdelay>,<options>,<persistent dir>]
```

 The count of matched lines in a monitored log file that is rotated.
 Return value: *Integer*.
 See [supported platforms](#).

Parameters:

- **file regexp** - the absolute path to file, with the file name specified using a regular [expression](#). Note that the regular expression applies only to the file name and does not need to match the entire name (e.g., /path/to/agent will match zabbix_agentd.log).

- **regexp** - a regular [expression](#) describing the required pattern.

- **encoding** - the code page [identifier](#).

- **maxproclines** - the maximum number of new lines per second the agent will analyze (cannot exceed 10000). The default value is 10*MaxLinesPerSecond' in [zabbix_agentd.conf](#).

- **mode** - possible values: *all* (default) or *skip* - skip processing of older data (affects only newly created items).

- **maxdelay** - the maximum delay in seconds. Type: float. Values: 0 - (default) never ignore log file lines; > 0.0 - ignore older lines in order to get the most recent lines analyzed within "maxdelay" seconds. Read the [maxdelay](#) notes before using it!

- **options** - the type of log file rotation and other options. Possible values:
rotate (default),
copytruncate - note that *copytruncate* cannot be used together with *maxdelay*. In this case *maxdelay* must be 0 or not specified; see [copytruncate](#) notes,
mtime-reread - non-unique records, reread if modification time or size changes (default),
mtime-noread - non-unique records, reread only if the size changes (ignore modification time change).

- **persistent dir** (only in zabbix_agentd on Unix systems; not supported in Zabbix agent 2) - the absolute pathname of directory where to store persistent files. See also additional notes on [persistent files](#).

Comments:

- The item must be configured as an [active check](#);
- Matching lines are counted in the new lines since the last log check by the agent, and thus depend on the item update interval;
- Log rotation is based on the last modification time of files;
- In the file regexp parameter, the log directory path and log file regular expression must be separated by the correct directory separator:
 - on Windows, the separator must be a backslash (\); forward slashes may be tolerated at other positions, except the one that separates the log directory path and the log file regular expression (see examples below).
 - on other systems, it must be a forward slash (/).

Examples for Windows:

```
logrt.count["c:/dir1/dir2/dir3\\filename.*\\.log","pattern_to_match"] #this item will count the number of matches for  
logrt.count["//example.com/share/dir1/dir2/dir3\\filename.*\\.log","pattern_to_match"] #this item will count the number of matches for
```

Examples for other systems:

```
logrt.count["/home/zabbix/logs/~logfile[0-9]{1,3}$",,,100] #this item will count the number of matches for  
logrt.count["/home/user/~logfile_.*_[0-9]{1,3}$","pattern_to_match","UTF-8",100] #this item will count the number of matches for
```

```
modbus.get[endpoint,<slave id>,<function>,<address>,<count>,<type>,<endianness>,<offset>]
```

 Reads Modbus data.
 Return value: *JSON object*.
 [Supported platforms](#): Linux.

Parameters:

- **endpoint** - the endpoint defined as protocol://connection_string;

- **slave id** - the slave ID;

- **function** - the Modbus function;

- **address** - the address of first registry, coil or input;

- **count** - the number of records to read;

- **type** - the type of data;

- **endianness** - the endianness configuration;

- **offset** - the number of registers, starting from 'address', the results of which will be discarded.

See a [detailed description](#) of parameters.

```
net.dns[<ip>,<name>,<type>,<timeout>,<count>,<protocol>]
```

 Checks the status of a DNS service.
 Return values: 0 - DNS resolution failed (DNS server did not respond or returned an error); 1 - DNS resolution succeeded.
 See [supported platforms](#).

Parameters:

- **ip** (ignored on Windows unless using Zabbix agent 2) - the IP address of DNS server (leave empty for the default DNS server);
- **name** - the DNS name to query;
- **type** - the record type to be queried (default is *SOA*);
- **timeout** (ignored on Windows unless using Zabbix agent 2) - the timeout for the request in seconds (default is 1 second);
- **count** (ignored on Windows unless using Zabbix agent 2) - the number of tries for the request (default is 2);
- **protocol** - the protocol used to perform DNS queries: *udp* (default) or *tcp*.

Comments:

- The possible values for *type* are: *ANY, A, NS, CNAME, MB, MG, MR, PTR, MD, MF, MX, SOA, NULL, WKS* (not supported for Zabbix agent on Windows, Zabbix agent 2 on all OS), *HINFO, MINFO, TXT, SRV*
- For reverse DNS lookups (when *type* is set to *PTR*), you can provide the DNS name in both reversed and non-reversed format (see examples below). Note that when *PTR* record is requested, the DNS name is actually an IP address.
- Internationalized domain names are not supported, please use IDNA encoded names instead.

Examples:

```
net.dns[198.51.100.1,example.com,MX,2,1]
```

```
net.dns[,198.51.100.1,PTR]
```

```
net.dns[,1.100.51.198.in-addr.arpa,PTR]
```

```
net.dns[,2a00:1450:400f:800::200e,PTR]
```

```
net.dns[,e.0.0.2.0.0.0.0.0.0.0.0.0.0.0.0.0.8.0.f.0.0.4.0.5.4.1.0.0.a.2.ip6.arpa,PTR]
```

```
net.dns.perf[<ip>,name,<type>,<timeout>,<count>,<protocol>]
```

 Checks the performance of a DNS service.
 Return value: *Float* (0 - service is down; seconds - the number of seconds spent waiting for a response from the service).
 See [supported platforms](#).

Parameters:

- **ip** (ignored on Windows unless using Zabbix agent 2) - the IP address of DNS server (leave empty for the default DNS server);
- **name** - the DNS name to query;
- **type** - the record type to be queried (default is *SOA*);
- **timeout** (ignored on Windows unless using Zabbix agent 2) - the timeout for the request in seconds (default is 1 second);
- **count** (ignored on Windows unless using Zabbix agent 2) - the number of tries for the request (default is 2);
- **protocol** - the protocol used to perform DNS queries: *udp* (default) or *tcp*.

Comments:

- The possible values for *type* are:
ANY, A, NS, CNAME, MB, MG, MR, PTR, MD, MF, MX, SOA, NULL, WKS (not supported for Zabbix agent on Windows, Zabbix agent 2 on all OS), *HINFO, MINFO, TXT, SRV*
- For reverse DNS lookups (when *type* is set to *PTR*), you can provide the DNS name in both reversed and non-reversed format (see examples below). Note that when *PTR* record is requested, the DNS name is actually an IP address.
- Internationalized domain names are not supported, please use IDNA encoded names instead.
- The item returns a response time instead of 0 when the DNS server responds with an error code (for example, *NXDOMAIN* or *SERVFAIL*).

Examples:

```
net.dns.perf[198.51.100.1,example.com,MX,2,1]
```

```
net.dns.perf[,198.51.100.1,PTR]
```

```
net.dns.perf[,1.100.51.198.in-addr.arpa,PTR]
```

```
net.dns.perf[,2a00:1450:400f:800::200e,PTR]
```

```
net.dns.perf[,e.0.0.2.0.0.0.0.0.0.0.0.0.0.0.0.0.8.0.f.0.0.4.0.5.4.1.0.0.a.2.ip6.arpa,PTR]
```

```
net.dns.record[<ip>,name,<type>,<timeout>,<count>,<protocol>]
```

 Performs a DNS query.

Zabbix agent 2 also provides [net.dns.get](#), which offers additional features such as more record types and greater control over DNS monitoring. Return value: a character string with the required type of information.
 See [supported platforms](#).

Parameters:

- **ip** (ignored on Windows unless using Zabbix agent 2) - the IP address of DNS server (leave empty for the default DNS server);
- **name** - the DNS name to query;

- **type** - the record type to be queried (default is *SOA*);
- **timeout** (ignored on Windows unless using Zabbix agent 2) - the timeout for the request in seconds (default is 1 second);
- **count** (ignored on Windows unless using Zabbix agent 2) - the number of tries for the request (default is 2);
- **protocol** - the protocol used to perform DNS queries: *udp* (default) or *tcp*.

Comments:

- The possible values for type are: *ANY, A, NS, CNAME, MB, MG, MR, PTR, MD, MF, MX, SOA, NULL, WKS* (not supported for Zabbix agent on Windows, Zabbix agent 2 on all OS), *HINFO, MINFO, TXT, SRV*
- For reverse DNS lookups (when type is set to *PTR*), you can provide the DNS name in reversed or non-reversed format (see examples below). Note that when *PTR* record is requested, the DNS name is actually an IP address.
- Internationalized domain names are not supported, please use IDNA encoded names instead.

Examples:

```
net.dns.record[198.51.100.1,example.com,MX,2,1]
```

```
net.dns.record[,198.51.100.1,PTR]
```

```
net.dns.record[,1.100.51.198.in-addr.arpa,PTR]
```

```
net.dns.record[,2a00:1450:400f:800::200e,PTR]
```

```
net.dns.record[,e.0.0.2.0.0.0.0.0.0.0.0.0.0.0.0.8.0.f.0.0.4.0.5.4.1.0.0.a.2.ip6.arpa,PTR]
```

```
net.if.collisions[if]
```

 The number of out-of-window collisions.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, MacOS X, OpenBSD, NetBSD. Root privileges are required on NetBSD.

Parameter:

- **if** - network interface name

```
net.if.discovery
```

 The list of network interfaces. Used for low-level discovery.
 Return value: *JSON object*.
 Supported platforms: Linux, FreeBSD, Solaris, HP-UX, AIX, OpenBSD, NetBSD.

```
net.if.in[if,<mode>]
```

 The incoming traffic statistics on a network interface.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris⁵, HP-UX, AIX, MacOS X, OpenBSD, NetBSD. Root privileges are required on NetBSD.

Parameters:

- **if** - network interface name (Unix); network interface full description or IPv4 address; or, if in braces, network interface GUID (Windows);
- **mode** - possible values:
bytes - number of bytes (default)
packets - number of packets
errors - number of errors
dropped - number of dropped packets
overruns (fifo) - the number of FIFO buffer errors
frame - the number of packet framing errors
compressed - the number of compressed packets received by the device driver
multicast - the number of multicast frames received by the device driver

Comments:

- You may use this key with the *Change per second* preprocessing step in order to get the bytes-per-second statistics;
- The *dropped* mode is supported only on Linux, FreeBSD, HP-UX, MacOS X, OpenBSD, NetBSD;
- The *overruns, frame, compressed, multicast* modes are supported only on Linux;
- On HP-UX this item does not provide details on loopback interfaces (e.g. lo0).

Examples:

```
net.if.in[eth0]
```

```
net.if.in[eth0,errors]
```

```
net.if.out[if,<mode>]
```

 The outgoing traffic statistics on a network interface.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris⁵, HP-UX, AIX, MacOS X, OpenBSD, NetBSD. Root privileges are required on NetBSD.

Parameters:

- **if** - network interface name (Unix); network interface full description or IPv4 address; or, if in braces, network interface GUID (Windows);

- **mode** - possible values:
bytes - number of bytes (default)
packets - number of packets
errors - number of errors
dropped - number of dropped packets
overruns (fifo) - the number of FIFO buffer errors
collisions (colls) - the number of collisions detected on the interface
carrier - the number of carrier losses detected by the device driver
compressed - the number of compressed packets transmitted by the device driver

Comments:

- You may use this key with the *Change per second* preprocessing step in order to get the bytes-per-second statistics;
- The *dropped* mode is supported only on Linux, HP-UX;
- The *overruns*, *collision*, *carrier*, *compressed* modes are supported only on Linux;
- On HP-UX this item does not provide details on loopback interfaces (e.g. lo0).

Examples:

```
net.if.out[eth0]
net.if.out[eth0,errors]
net.if.total[if,<mode>]
```

 The sum of incoming and outgoing traffic statistics on a network interface.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris⁵, HP-UX, AIX, MacOS X, OpenBSD, NetBSD. Root privileges are required on NetBSD.

Parameters:

- **if** - network interface name (Unix); network interface full description or IPv4 address; or, if in braces, network interface GUID (Windows);
- **mode** - possible values:
bytes - number of bytes (default)
packets - number of packets
errors - number of errors
dropped - number of dropped packets
overruns (fifo) - the number of FIFO buffer errors
collisions (colls) - the number of collisions detected on the interface
compressed - the number of compressed packets transmitted or received by the device driver

Comments:

- You may use this key with the *Change per second* preprocessing step in order to get the bytes-per-second statistics;
- The *dropped* mode is supported only on Linux, HP-UX. Dropped packets are supported only if both `net.if.in` and `net.if.out` work for dropped packets on your platform.
- The *overruns*, *collision*, *compressed* modes are supported only on Linux;
- On HP-UX this item does not provide details on loopback interfaces (e.g. lo0).

Examples:

```
net.if.total[eth0]
net.if.total[eth0,errors]
net.tcp.listen[port]
```

 Checks if this TCP port is in LISTEN state.
 Return values: 0 - it is not in LISTEN state; 1 - it is in LISTEN state.
 Supported platforms: Linux, FreeBSD, Solaris, MacOS X.

Parameter:

- **port** - TCP port number

On Linux kernels 2.6.14 and above, the information about listening TCP sockets is obtained from the kernel's NETLINK interface, if possible. Otherwise, the information is retrieved from `/proc/net/tcp` and `/roc/net/tcp6` files.

Example:

```
net.tcp.listen[80]
net.tcp.port[<ip>,port]
```

 Checks if it is possible to make a TCP connection to the specified port.
 Return values: 0 - cannot connect; 1 - can connect.
 See **supported platforms**.

Parameters:

- **ip** - the IP address or DNS name (default is 127.0.0.1);
- **port** - the port number.

Comments:

- For simple TCP performance testing use `net.tcp.service.perf[tcp,<ip>,<port>]`;
- These checks may result in additional messages in system daemon logfiles (SMTP and SSH sessions being logged usually).

Example:

`net.tcp.port[,80]` #this item can be used to test the web server availability running on port 80

`net.tcp.service[service,<ip>,<port>]`

 Checks if a service is running and accepting TCP connections.
 Return values: 0 - service is down; 1 - service is running.
 See [supported platforms](#).

Parameters:

- **service** - *ssh, ldap, smtp, ftp, http, pop, nntp, imap, tcp, https, or telnet* (see [details](#));
- **ip** - the IP address or DNS name (default is 127.0.0.1);
- **port** - the port number (by default the standard service port number is used).

Comments:

- These checks may result in additional messages in system daemon logfiles (SMTP and SSH sessions being logged usually);
- Checking of encrypted protocols (like IMAP on port 993 or POP on port 995) is currently not supported. As a workaround, please use `net.tcp.port[]` for checks like these.
- Checking of LDAP and HTTPS on Windows is only supported by Zabbix agent 2;
- The telnet check looks for a login prompt (':' at the end).

Example:

`net.tcp.service[ftp,,45]` #this item can be used to test the availability of FTP server on TCP port 45

`net.tcp.service.perf[service,<ip>,<port>]`

 Checks the performance of a TCP service.
 Return values: *Float* (0 - service is down; seconds - the number of seconds spent waiting for a response from the service).
 See [supported platforms](#).

Parameters:

- **service** - *ssh, ldap, smtp, ftp, http, pop, nntp, imap, tcp, https, or telnet* (see [details](#));
- **ip** - the IP address or DNS name (default is 127.0.0.1);
- **port** - the port number (by default the standard service port number is used).

Comments:

- Checking of encrypted protocols (like IMAP on port 993 or POP on port 995) is currently not supported. As a workaround, please use `net.tcp.service.perf[tcp,<ip>,<port>]` for checks like these.
- The telnet check looks for a login prompt (':' at the end).

Example:

`net.tcp.service.perf[ssh]` #this item can be used to test the speed of initial response from the SSH server

`net.tcp.socket.count[<laddr>,<lport>,<raddr>,<rport>,<state>]`

 Returns the number of TCP sockets that match parameters.
 Return value: *Integer*.
 [Supported platforms](#): Linux.

Parameters:

- **laddr** - the local IPv4/6 address or CIDR subnet;
- **lport** - the local port number or service name;
- **raddr** - the remote IPv4/6 address or CIDR subnet;
- **rport** - the remote port number or service name;
- **state** - the connection state (*established, syn_sent, syn_recv, fin_wait1, fin_wait2, time_wait, close, close_wait, last_ack, listen, closing*).

Example:

`net.tcp.socket.count[,80,,,established]` #the number of connections to local TCP port 80 in the established

`net.udp.listen[port]`

 Checks if this UDP port is in LISTEN state.
 Return values: 0 - it is not in LISTEN state; 1 - it is in LISTEN state.
 [Supported platforms](#): Linux, FreeBSD, Solaris, MacOS X.

Parameter:

- **port** - UDP port number

Example:

`net.udp.listen[68]`

net.udp.service[service,<ip>,<port>]

 Checks if a service is running and responding to UDP requests.
 Return values: 0 - service is down; 1 - service is running.
 See [supported platforms](#).

Parameters:

- **service** - *ntp* (see [details](#));
- **ip** - the IP address or DNS name (default is 127.0.0.1);
- **port** - the port number (by default the standard service port number is used).

Example:

```
net.udp.service[ntp,,45] #this item can be used to test the availability of NTP service on UDP port 45
net.udp.service.perf[service,<ip>,<port>]
```

 Checks the performance of a UDP service.
 Return values: *Float* (0 - service is down; seconds - the number of seconds spent waiting for a response from the service).
 See [supported platforms](#).

Parameters:

- **service** - *ntp* (see [details](#));
- **ip** - the IP address or DNS name (default is 127.0.0.1);
- **port** - the port number (by default the standard service port number is used).

Example:

```
net.udp.service.perf[ntp] #this item can be used to test response time from NTP service
net.udp.socket.count[<laddr>,<lport>,<raddr>,<rport>,<state>]
```

 Returns the number of UDP sockets that match parameters.
 Return value: *Integer*.
 [Supported platforms](#): Linux.

Parameters:

- **laddr** - the local IPv4/6 address or CIDR subnet;
- **lport** - the local port number or service name;
- **raddr** - the remote IPv4/6 address or CIDR subnet;
- **rport** - the remote port number or service name;
- **state** - the connection state (*established*, *unconn*).

Example:

```
net.udp.socket.count[,,,,established] #returns the number of UDP sockets in the connected state
proc.cpu.util[<name>,<user>,<type>,<cmdline>,<mode>,<zone>]
```

 The process CPU utilization percentage.
 Return value: *Float*.
 [Supported platforms](#): Linux, Solaris⁶.

Parameters:

- **name** - the process name (default is *all processes*);
- **user** - the user name (default is *all users*);
- **type** - the CPU utilization type: *total* (default), *user*, or *system*;
- **cmdline** - filter by command line (it is a regular [expression](#));
- **mode** - the data gathering mode: *avg1* (default), *avg5*, or *avg15*;
- **zone** - the target zone: *current* (default) or *all*. This parameter is supported on Solaris only.

Comments:

- The returned value is based on a single CPU core utilization percentage. For example, the CPU utilization of a process fully using two cores is 200%.
- The process CPU utilization data is gathered by a collector which supports the maximum of 1024 unique (by name, user and command line) queries. Queries not accessed during the last 24 hours are removed from the collector.
- When setting the zone parameter to *current* (or default) in case the agent has been compiled on a Solaris without zone support, but running on a newer Solaris where zones are supported, then the agent will return NOTSUPPORTED (the agent cannot limit results to only the current zone). However, *all* is supported in this case.

Examples:

```
proc.cpu.util[,root] #CPU utilization of all processes running under the "root" user
proc.cpu.util[zabbix_server,zabbix] #CPU utilization of all zabbix_server processes running under the zabb
```

proc.get[<name>,<user>,<cmdline>,<mode>]

 The list of OS processes and their parameters. Can be used for low-level discovery.
 Return value: *JSON object*.
 Supported platforms: Linux, FreeBSD, Windows, OpenBSD, NetBSD.

Parameters:

- **name** - the process name (default *all processes*);
- **user** - the user name (default *all users*);
- **cmdline** - filter by command line (it is a regular **expression**). This parameter is not supported for Windows; on other platforms it is not supported if mode is set to 'summary'.
- **mode** - possible values:
process (default), *thread* (not supported for NetBSD), *summary*. See a list of **process parameters** returned for each mode and OS.

Comments:

- If a value cannot be retrieved, for example, because of an error (process already died, lack of permissions, system call failure), -1 will be returned;
- See **notes** on selecting processes with name and cmdline parameters (Linux-specific).

Examples:

```
proc.get[zabbix_server,zabbix,,process] #list of all zabbix_server processes running under the zabbix user
proc.get[java,,thread] #list of all Java processes, returns one entry per thread
proc.get[,zabbix,,summary] #combined data for processes of each type running under the zabbix user, return
proc.mem[<name>,<user>,<mode>,<cmdline>,<memtype>]
```

 The memory used by the process in bytes.
 Return value: *Integer* - with mode as *max*, *min*, *sum*; *Float* - with mode as *avg*
 Supported platforms: Linux, FreeBSD, Solaris, AIX, OpenBSD, NetBSD.

Parameters:

- **name** - the process name (default is *all processes*);
- **user** - the user name (default is *all users*);
- **mode** - possible values: *avg*, *max*, *min*, or *sum* (default);
- **cmdline** - filter by command line (it is a regular **expression**);
- **memtype** - the **type of memory** used by process

Comments:

- The **memtype** parameter is supported only on Linux, FreeBSD, Solaris⁶, AIX;
- When several processes use shared memory, the sum of memory used by processes may result in large, unrealistic values.

See **notes** on selecting processes with name and cmdline parameters (Linux-specific).

When this item is invoked from the command line and contains a command line parameter (e.g. using the agent test mode: `zabbix_agentd -t proc.mem[, , ,apache2]`), one extra process will be counted, as the agent will count itself.

Examples:

```
proc.mem[,root] #the memory used by all processes running under the "root" user
proc.mem[zabbix_server,zabbix] #the memory used by all zabbix_server processes running under the zabbix user
proc.mem[,oracle,max,oracleZABBIX] #the memory used by the most memory-hungry process running under Oracle
proc.num[<name>,<user>,<state>,<cmdline>,<zone>]
```

 The number of processes.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris⁶, HP-UX, AIX, OpenBSD, NetBSD.

Parameters:

- **name** - the process name (default is *all processes*);
- **user** - the user name (default is *all users*);
- **state** - possible values:
all (default),
disk - uninterruptible sleep,
run - running,
sleep - interruptible sleep,
trace - stopped,
zomb - zombie;
- **cmdline** - filter by command line (it is a regular **expression**);
- **zone** - the target zone: *current* (default), or *all*. This parameter is supported on Solaris only.

Comments:

- The *disk* and *trace* state parameters are supported only on Linux, FreeBSD, OpenBSD, NetBSD;
- When this item is invoked from the command line and contains a command line parameter (e.g. using the agent test mode: `zabbix_agentd -t proc.num[, , ,apache2]`), one extra process will be counted, as the agent will count itself;

- When setting the zone parameter to *current* (or default) in case the agent has been compiled on a Solaris without zone support, but running on a newer Solaris where zones are supported, then the agent will return NOTSUPPORTED (the agent cannot limit results to only the current zone). However, *all* is supported in this case.
- See [notes](#) on selecting processes with name and cmdline parameters (Linux-specific).

Examples:

```
proc.num[,mysql] #the number of processes running under the mysql user
proc.num[apache2,www-data] #the number of apache2 processes running under the www-data user
proc.num[,oracle,sleep,oracleZABBIX] #the number of processes in sleep state running under Oracle having c
```

```
sensor[device,sensor,<mode>]
```

 Hardware sensor reading.
 Return value: *Float*.
 Supported platforms: Linux, OpenBSD.

Parameters:

- **device** - the device name, can be a regular expression if mode is omitted;
- **sensor** - the sensor name, can be a regular expression if mode is omitted;
- **mode** - possible values: *avg*, *max*, or *min* (if this parameter is omitted, device and sensor are treated verbatim).

Comments:

- Reads /proc/sys/dev/sensors on Linux 2.4;
- Reads /sys/class/hwmon on Linux 2.6+. See a more detailed description of [sensor](#) item on Linux.
- Reads the *hw.sensors* MIB on OpenBSD.

Examples:

```
sensor[w83781d-i2c-0-2d,temp1]
sensor[cpu0,temp0] #the temperature of one CPU
sensor["cpu[0-2]$",temp,avg] #the average temperature of the first three CPUs
```

```
system.boottime
```

 The system boot time.
 Return value: *Integer (Unix timestamp)*.
 Supported platforms: Linux, FreeBSD, Solaris, MacOS X, OpenBSD, NetBSD.

```
system.cpu.discovery
```

 The list of detected CPUs/CPU cores. Used for low-level discovery.
 Return value: *JSON object*.
 See [supported platforms](#).

```
system.cpu.intr
```

 The device interrupts.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, OpenBSD, NetBSD.

```
system.cpu.load[<cpu>,<mode>]
```

 The [CPU load](#).
 Return value: *Float*.
 See [supported platforms](#).

Parameters:

- **cpu** - possible values: *all* (default) or *percpu* (the total load divided by online CPU count);
- **mode** - possible values: *avg1* (one-minute average, default), *avg5*, or *avg15*.

Example:

```
system.cpu.load[,avg5]
system.cpu.num[<type>]
```

 The number of CPUs.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris, HP-UX, AIX, MacOS X, OpenBSD, NetBSD.

Parameter:

- **type** - possible values: *online* (default) or *max*

The *max* type parameter is supported only on Linux, FreeBSD, Solaris, MacOS X.

Example:

```
system.cpu.num
```

system.cpu.switches

 The count of context switches.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, OpenBSD, NetBSD.

system.cpu.util[<cpu>,<type>,<mode>,<logical or physical>]

 The CPU utilization percentage.
 Return value: *Float*.
 Supported platforms: Linux, FreeBSD, Solaris, HP-UX, AIX, OpenBSD, NetBSD.

Parameters:

- **cpu** - <CPU number> or *all* (default);
- **type** - possible values: *user* (default), *idle*, *nice*, *system*, *iowait*, *interrupt*, *softirq*, *steal*, *spin* (on OpenBSD), *guest* (on Linux kernels 2.6.24 and above), or *guest_nice* (on Linux kernels 2.6.33 and above);
- **mode** - possible values: *avg1* (one-minute average, default), *avg5*, or *avg15*;
- **logical or physical** - possible values: *logical* (default) or *physical*. This parameter is supported on AIX only.

Comments:

- The *nice* type parameter is supported only on Linux, FreeBSD, HP-UX, OpenBSD, NetBSD.
- The *iowait* type parameter is supported only on Linux 2.6 and later, Solaris, AIX.
- The *interrupt* type parameter is supported only on Linux 2.6 and later, FreeBSD, OpenBSD.
- The *softirq*, *steal*, *guest*, *guest_nice* type parameters are supported only on Linux 2.6 and later.
- The *avg5* and *avg15* mode parameters are supported on Linux, FreeBSD, Solaris, HP-UX, AIX, OpenBSD, NetBSD.

Example:

system.cpu.util[0,user,avg5]

system.hostname[<type>,<transform>]

 The system host name.
 Return value: *String*.
 See **supported platforms**.

Parameters:

- **type** - possible values: *netbios* (default on Windows), *host* (default on Linux), *shorthost* (returns part of the hostname before the first dot, a full string for names without dots), *fqdn* (returns Fully Qualified Domain Name);
- **transform** - possible values: *none* (default) or *lower* (convert to lowercase).

The value is acquired by taking nodename from the uname() system API output.

Examples of returned values:

system.hostname → linux-w7x1

system.hostname → example.com

system.hostname[shorthost] → example

system.hostname → WIN-SERV2008-I6

system.hostname[host] → Win-Serv2008-I6Long

system.hostname[host,lower] → win-serv2008-i6long

system.hostname[fqdn,lower] → blog.zabbix.com

system.hw.chassis[<info>]

 The chassis information.
 Return value: *String*.
 Supported platforms: Linux.

Parameter:

- **info** - possible values: *full* (default), *model*, *serial*, *type*, or *vendor*

Comments:

- This item key depends on the availability of the **SMBIOS** table;
- It will try to read the DMI table from sysfs, if sysfs access fails then try reading directly from memory;
- **Root permissions** are required because the value is acquired by reading from sysfs or memory.

Example:

system.hw.chassis[full] → Hewlett-Packard HP Pro 3010 Small Form Factor PC CZXXXXXXXX Desktop

system.hw.cpu[<cpu>,<info>]

 The CPU information.
 Return value: *String* or *Integer*.
 Supported platforms: Linux.

Parameters:

- **cpu** - <CPU number> or *all* (default);

- **info** - possible values: *full* (default), *curfreq*, *maxfreq*, *model* or *vendor*.

Comments:

- Gathers info from `/proc/cpuinfo` and `/sys/devices/system/cpu/[cpunum]/cpufreq/cpuinfo_max_freq`;
- If a CPU number and *curfreq* or *maxfreq* is specified, a numeric value is returned (Hz).

Example:

```
system.hw.cpu[0,vendor] → AuthenticAMD
```

```
system.hw.devices[<type>]
```

 The listing of PCI or USB devices.
 Return value: *Text*.
 Supported platforms: Linux.

Parameter:

- **type** - *pci* (default) or *usb*

Returns the output of either the `lspci` or `lsusb` utility (executed without any parameters).

Example:

```
system.hw.devices → 00:00.0 Host bridge: Advanced Micro Devices [AMD] RS780 Host Bridge
```

```
system.hw.macaddr[<interface>,<format>]
```

 The listing of MAC addresses.
 Return value: *String*.
 Supported platforms: Linux.

Parameters:

- **interface** - *all* (default) or a regular **expression**;
- **format** - *full* (default) or *short*

Comments:

- Lists MAC addresses of the interfaces whose name matches the given **interface** regular **expression** (*all* lists for all interfaces);
- If **format** is specified as *short*, interface names and identical MAC addresses are not listed.

Example:

```
system.hw.macaddr["eth0$",full] → [eth0] 00:11:22:33:44:55
```

```
system.localtime[<type>]
```

 The system time.
 Return value: *Integer* - with type as *utc*; *String* - with type as *local*.
 See **supported platforms**.

Parameters:

- **type** - possible values: *utc* - (default) the time since the Epoch (00:00:00 UTC, January 1, 1970), measured in seconds or *local* - the time in the 'yyyy-mm-dd,hh:mm:ss.nnn, +hh:mm' format

Must be used as a **passive check** only.

Example:

```
system.localtime[local] #create an item using this key and then use it to display the host time in the *CLI
```

```
system.run[command,<mode>]
```

 Run the specified command on the host.
 Return value: *Text* result of the command or 1 - with mode as *nowait* (regardless of the command result).
 See **supported platforms**.

Parameters:

- **command** - command for execution;

- **mode** - possible values: *wait* - wait end of execution (default) or *nowait* - do not wait.

Comments:

- This item is disabled by default. Learn how to **enable them**;
- The return value of the item is a standard output together with a standard error produced by the command. **Exit code checking** is not performed;
- To be processed correctly, the return value of the command must be of text data type. An empty result is also allowed;
- The return value is limited to 16MB (including trailing whitespace that is truncated); **database limits** also apply;
- See also: **Command execution**.

Example:

`system.run[ls -l /] #return a detailed file list of the root directory`

`system.stat[resource,<type>]`

 The system statistics.
 Return value: *Integer* or *float*.
 Supported platforms: AIX.

Parameters:

- **ent** - the number of processor units this partition is entitled to receive (float);
- **kthr,<type>** - information about kernel thread states:
r - average number of runnable kernel threads (float)
b - average number of kernel threads placed in the Virtual Memory Manager wait queue (float)
- **memory,<type>** - information about the usage of virtual and real memory:
avm - active virtual pages (integer)
fre - size of the free list (integer)
- **page,<type>** - information about page faults and paging activity:
fi - file page-ins per second (float)
fo - file page-outs per second (float)
pi - pages paged in from paging space (float)
po - pages paged out to paging space (float)
fr - pages freed (page replacement) (float)
sr - pages scanned by page-replacement algorithm (float)
- **faults,<type>** - trap and interrupt rate:
in - device interrupts (float)
sy - system calls (float)
cs - kernel thread context switches (float)
- **cpu,<type>** - breakdown of percentage usage of processor time:
us - user time (float)
sy - system time (float)
id - idle time (float)
wa - idle time during which the system had outstanding disk/NFS I/O request(s) (float)
pc - number of physical processors consumed (float)
ec - the percentage of entitled capacity consumed (float)
lbusy - indicates the percentage of logical processor(s) utilization that occurred while executing at the user and system level (float)
app - indicates the available physical processors in the shared pool (float)
- **disk,<type>** - disk statistics:
bps - indicates the amount of data transferred (read or written) to the drive in bytes per second (integer)
tps - indicates the number of transfers per second that were issued to the physical disk/tape (float)

Comments:

- Take note of the following limitations in these items:
`system.stat[cpu,app]` - supported only on AIX LPAR of type "Shared"
`system.stat[cpu,ec]` - supported on AIX LPAR of type "Shared" and "Dedicated" ("Dedicated" always returns 100 (percent))
`system.stat[cpu,lbusy]` - supported only on AIX LPAR of type "Shared"
`system.stat[cpu,pc]` - supported on AIX LPAR of type "Shared" and "Dedicated"
`system.stat[ent]` - supported on AIX LPAR of type "Shared" and "Dedicated"

`system.sw.arch`

 The software architecture information.
 Return value: *String*.
 See **supported platforms**.

The info is acquired from the `uname()` function.

Example:

`system.sw.arch` → i686

`system.sw.os[<info>]`

 The operating system information.
 Return value: *String*.
 Supported platforms: Linux, Windows.

Parameter:

- **info** - possible values: *full* (default), *short*, or *name*

The info is acquired from (note that not all files and options are present in all distributions):

- `/proc/version` (*full*) on Linux;
- `/proc/version_signature` (*short*) on Linux;
- the `PRETTY_NAME` parameter from `/etc/os-release` on Linux-systems supporting it or `/etc/issue.net` (*name*);
- the `HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion` registry key on Windows.

Examples:

`system.sw.os[short]` → Ubuntu 2.6.35-28.50-generic 2.6.35.11

`system.sw.os[full]` → [s|Windows 10 Enterprise 22621.1.asd64fre.ni_release.220506-1250 Build 22621.963]

`system.sw.os.get`

 Detailed information about the operating system (version, type, distribution name, minor and major version, etc).
 Return value: *JSON object*.
 Supported platforms: Linux, Windows.

`system.sw.packages[<regex>,<manager>,<format>]`

 The listing of installed packages.
 Return value: *Text*.
 Supported platforms: Linux.

Parameters:

- **regex** - *all* (default) or a regular **expression**;
- **manager** - *all* (default) or a package manager;
- **format** - *full* (default) or *short*.

Comments:

- Lists (alphabetically) installed packages whose name matches the given regular **expression** (*all* lists them all);
- Supported package managers (executed command): `
dpkg (dpkg --get-selections)
pkgtool (ls /var/log/packages)
rpm (rpm -qa)
pacman (pacman -Q)
portage`
- If **format** is specified as *full*, packages are grouped by package managers (each manager on a separate line beginning with its name in square brackets);
- If **format** is specified as *short*, packages are not grouped and are listed on a single line.

Example:

```
system.sw.packages[mini,dpkg,short] → python-minimal, python2.6-minimal, ubuntu-minimal
```

```
system.sw.packages.get[<regex>,<manager>]
```

`
` A detailed listing of installed packages.`
` Return value: *JSON object*.`
` **Supported platforms:** Linux.

Parameters:

- **regex** - *all* (default) or a regular **expression**;
- **manager** - *all* (default) or a package manager (possible values: *rpm*, *dpkg*, *pkgtool*, *pacman*, or *portage*).

Comments:

- Returns unformatted JSON with the installed packages whose name matches the given regular expression;
- The output is an array of objects each containing the following keys: name, manager, version, size, architecture, buildtime and installtime (see **more details**).

```
system.swap.in[<device>,<type>]
```

`
` The swap-in (from device into memory) statistics.`
` Return value: *Integer*.`
` **Supported platforms:** Linux, FreeBSD, OpenBSD.

Parameters:

- **device** - specify the device used for swapping (Linux only) or *all* (default);
- **type** - possible values: *count* (number of swapins, default on non-Linux platforms), *sectors* (sectors swapped in), or *pages* (pages swapped in, default on Linux).

Comments:

- The source of this information is:`
/proc/swaps, /proc/partitions, /proc/stat (Linux 2.4)
/proc/swaps, /proc/diskstats, /proc/vmstat (Linux 2.6)`
- Note that *pages* will only work if device was not specified;
- The *sectors* type parameter is supported only on Linux.

Example:

```
system.swap.in[,pages]
```

```
system.swap.out[<device>,<type>]
```

`
` The swap-out (from memory onto device) statistics.`
` Return value: *Integer*.`
` **Supported platforms:** Linux, FreeBSD, OpenBSD.

Parameters:

- **device** - specify the device used for swapping (Linux only) or *all* (default);
- **type** - possible values: *count* (number of swapouts, default on non-Linux platforms), *sectors* (sectors swapped out), or *pages* (pages swapped out, default on Linux).

Comments:

- The source of this information is:`
/proc/swaps, /proc/partitions, /proc/stat (Linux 2.4)
/proc/swaps, /proc/diskstats, /proc/vmstat (Linux 2.6)`
- Note that *pages* will only work if device was not specified;
- The *sectors* type parameter is supported only on Linux.

Example:

```
system.swap.out[,pages]
```

system.swap.size[<device>,<type>]

 The swap space size in bytes or in percentage from total.
 Return value: *Integer* - for bytes; *Float* - for percentage.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, OpenBSD.

Parameters:

- **device** - specify the device used for swapping (FreeBSD only) or *all* (default);
- **type** - possible values: *free* (free swap space, default), *pfree* (free swap space, in percent), *pused* (used swap space, in percent), *total* (total swap space), or *used* (used swap space).

Comments:

- Note that *pfree*, *pused* are not supported on Windows if swap size is 0;
- If device is not specified Zabbix agent will only take into account swap devices (files), the physical memory will be ignored. For example, on Solaris systems the `swap -s` command includes a portion of physical memory and swap devices (unlike `swap -l`).

Example:

system.swap.size[,pfree] → free swap space percentage

system.uname

 Identification of the system.
 Return value: *String*.
 See **supported platforms**.

Comments:

- On UNIX the value for this item is obtained with the `uname()` system call;
- On Windows the item returns the OS architecture, whereas on UNIX it returns the CPU architecture.

Examples:

system.uname → FreeBSD localhost 4.2-RELEASE FreeBSD 4.2-RELEASE #0: Mon Nov i386

system.uname → Windows ZABBIX-WIN 6.0.6001 Microsoft® Windows Server® 2008 Standard Service Pack 1 x86

system.uptime

 The system uptime in seconds.
 Return value: *Integer*.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, MacOS X, OpenBSD, NetBSD.

In **item configuration**, use **s** or **uptime** units to get readable values.

system.users.num

 The number of users logged in.
 Return value: *Integer*.
 See **supported platforms**.

The **who** command is used on the agent side to obtain the value.

vfs.dev.discovery

 The list of block devices and their type. Used for low-level discovery.
 Return value: *JSON object*.
 Supported platforms: Linux.

vfs.dev.read[<device>,<type>,<mode>]

 The disk read statistics.
 Return value: *Integer* - with type in *sectors*, *operations*, *bytes*; *Float* - with type in *sps*, *ops*, *bps*.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, OpenBSD.

Parameters:

- **device** - disk device (default is *all* ³);
- **type** - possible values: *sectors*, *operations*, *bytes*, *sps*, *ops*, or *bps* (*sps*, *ops*, *bps* stand for: sectors, operations, bytes per second, respectively);
- **mode** - possible values: *avg1* (one-minute average, default), *avg5*, or *avg15*. This parameter is supported only with type in: *sps*, *ops*, *bps*.

Comments:

- If using an update interval of three hours or more ², this item will always return '0';
- The *sectors* and *sps* type parameters are supported only on Linux;
- The *ops* type parameter is supported only on Linux and FreeBSD;
- The *bps* type parameter is supported only on FreeBSD;
- The *bytes* type parameter is supported only on FreeBSD, Solaris, AIX, OpenBSD;
- The *mode* parameter is supported only on Linux, FreeBSD;
- You may use relative device names (for example, *sda*) as well as an optional */dev/* prefix (for example, */dev/sda*);

- LVM logical volumes are supported;
- The default values of 'type' parameter for different OSes:
AIX - operations
FreeBSD - bps
Linux - sps
OpenBSD - operations
Solaris - bytes
- *sps*, *ops* and *bps* on supported platforms is limited to 1024 devices (1023 individual and one for *all*).

Example:

```
vfs.dev.read[,operations]
```

```
vfs.dev.write[<device>,<type>,<mode>]
```

 The disk write statistics.
 Return value: *Integer* - with type in *sectors*, *operations*, *bytes*; *Float* - with type in *sps*, *ops*, *bps*.
 Supported platforms: Linux, FreeBSD, Solaris, AIX, OpenBSD.

Parameters:

- **device** - disk device (default is *all* ³);
- **type** - possible values: *sectors*, *operations*, *bytes*, *sps*, *ops*, or *bps* (*sps*, *ops*, *bps* stand for: sectors, operations, bytes per second, respectively);
- **mode** - possible values: *avg1* (one-minute average, default), *avg5*, or *avg15*. This parameter is supported only with type in: *sps*, *ops*, *bps*.

Comments:

- If using an update interval of three hours or more ², this item will always return '0';
- The *sectors* and *sps* type parameters are supported only on Linux;
- The *ops* type parameter is supported only on Linux and FreeBSD;
- The *bps* type parameter is supported only on FreeBSD;
- The *bytes* type parameter is supported only on FreeBSD, Solaris, AIX, OpenBSD;
- The *mode* parameter is supported only on Linux, FreeBSD;
- You may use relative device names (for example, *sda*) as well as an optional */dev/* prefix (for example, */dev/sda*);
- LVM logical volumes are supported;
- The default values of 'type' parameter for different OSes:
AIX - operations
FreeBSD - bps
Linux - sps
OpenBSD - operations
Solaris - bytes
- *sps*, *ops* and *bps* on supported platforms is limited to 1024 devices (1023 individual and one for *all*).

Example:

```
vfs.dev.write[,operations]
```

```
vfs.dir.count[dir,<regex incl>,<regex excl>,<types incl>,<types excl>,<max depth>,<min size>,<max size>,<min age>,<max age>,<regex excl dir>]
```

 The directory entry count.
 Return value: *Integer*.
 See **supported platforms**.

Parameters:

- **dir** - the absolute path to directory;
- **regex incl** - a regular **expression** describing the name pattern of the entity (file, directory, symbolic link) to include; include all if empty (default value);
- **regex excl** - a regular **expression** describing the name pattern of the entity (file, directory, symbolic link) to exclude; don't exclude any if empty (default value);
- **types incl** - directory entry types to count, possible values: *file* - regular file, *dir* - subdirectory, *sym* - symbolic link, *sock* - socket, *bdev* - block device, *cdev* - character device, *fifo* - FIFO, *dev* - synonymous with "bdev,cdev", *all* - all types (default), i.e. "file,dir,sym,sock,bdev,cdev,fifo". Multiple types must be separated with comma and quoted.
- **types excl** - directory entry types (see *types incl*) to NOT count. If some entry type is in both *types incl* and *types excl*, directory entries of this type are NOT counted.
- **max depth** - the maximum depth of subdirectories to traverse:
-1 (default) - unlimited,
0 - no descending into subdirectories.
- **min size** - the minimum size (in bytes) for file to be counted. Smaller files will not be counted. **Memory suffixes** can be used.
- **max size** - the maximum size (in bytes) for file to be counted. Larger files will not be counted. **Memory suffixes** can be used.
- **min age** - the minimum age (in seconds) of directory entry to be counted. More recent entries will not be counted. **Time suffixes** can be used.
- **max age** - the maximum age (in seconds) of directory entry to be counted. Entries so old and older will not be counted (modification time). **Time suffixes** can be used.
- **regex excl dir** - a regular **expression** describing the name pattern of the directory to exclude. All content of the directory will be excluded (in contrast to *regex_excl*)

Comments:

- Environment variables, e.g. %APP_HOME%, \$HOME and %TEMP% are not supported;

- Pseudo-directories "." and ".." are never counted;
- Symbolic links are never followed for directory traversal;
- Both `regex incl` and `regex excl` are being applied to files and directories when calculating the entry count, but are ignored when picking subdirectories to traverse (if `regex incl` is "(?i)^.+\\.zip\$" and `max depth` is not set, then all subdirectories will be traversed, but only the files of type zip will be counted).
- The execution time is limited by the timeout value in agent [configuration](#) (3 sec). Since large directory traversal may take longer than that, no data will be returned and the item will turn unsupported. Partial count will not be returned.
- When filtering by size, only regular files have meaningful sizes. Under Linux and BSD, directories also have non-zero sizes (a few Kb typically). Devices have zero sizes, e.g. the size of `/dev/sda1` does not reflect the respective partition size. Therefore, when using `<min_size>` and `<max_size>`, it is advisable to specify `<types_incl>` as "file", to avoid surprises.

Examples:

```
vfs.dir.count[/dev] #monitors the number of devices in /dev (Linux)
vfs.dir.count["C:\\Users\\ADMINI~1\\AppData\\Local\\Temp"] #monitors the number of files in a temporary directory
vfs.dir.get[dir,<regex incl>,<regex excl>,<types incl>,<types excl>,<max depth>,<min size>,<max size>,<min age>,<max age>,<regex excl dir>]
```

 The directory entry list.
 Return value: *JSON object*.
 See [supported platforms](#).

Parameters:

- **dir** - the absolute path to directory;
- **regex incl** - a regular [expression](#) describing the name pattern of the entity (file, directory, symbolic link) to include; include all if empty (default value);
- **regex excl** - a regular [expression](#) describing the name pattern of the entity (file, directory, symbolic link) to exclude; don't exclude any if empty (default value);
- **types incl** - directory entry types to list, possible values: *file* - regular file, *dir* - subdirectory, *sym* - symbolic link, *sock* - socket, *bdev* - block device, *cdev* - character device, *fifo* - FIFO, *dev* - synonymous with "bdev,cdev", *all* - all types (default), i.e. "file,dir,sym,sock,bdev,cdev,fifo". Multiple types must be separated with comma and quoted.
- **types excl** - directory entry types (see `types incl`) to NOT list. If some entry type is in both `types incl` and `types excl`, directory entries of this type are NOT listed.
- **max depth** - the maximum depth of subdirectories to traverse:
-1 (default) - unlimited,
0 - no descending into subdirectories.
- **min size** - the minimum size (in bytes) for file to be listed. Smaller files will not be listed. [Memory suffixes](#) can be used.
- **max size** - the maximum size (in bytes) for file to be listed. Larger files will not be listed. [Memory suffixes](#) can be used.
- **min age** - the minimum age (in seconds) of directory entry to be listed. More recent entries will not be listed. [Time suffixes](#) can be used.
- **max age** - the maximum age (in seconds) of directory entry to be listed. Entries so old and older will not be listed (modification time). [Time suffixes](#) can be used.
- **regex excl dir** - a regular [expression](#) describing the name pattern of the directory to exclude. All content of the directory will be excluded (in contrast to `regex excl`)

Comments:

- Environment variables, e.g. %APP_HOME%, \$HOME and %TEMP% are not supported;
- Pseudo-directories "." and ".." are never listed;
- Symbolic links are never followed for directory traversal;
- Both `regex incl` and `regex excl` are being applied to files and directories when generating the entry list, but are ignored when picking subdirectories to traverse (if `regex incl` is "(?i)^.+\\.zip\$" and `max depth` is not set, then all subdirectories will be traversed, but only the files of type zip will be counted).
- The execution time is limited by the timeout value in agent [configuration](#). Since large directory traversal may take longer than that, no data will be returned and the item will turn unsupported. Partial list will not be returned.
- When filtering by size, only regular files have meaningful sizes. Under Linux and BSD, directories also have non-zero sizes (a few Kb typically). Devices have zero sizes, e.g. the size of `/dev/sda1` does not reflect the respective partition size. Therefore, when using `min size` and `max size`, it is advisable to specify `types incl` as "file", to avoid surprises.

Examples:

```
vfs.dir.get[/dev] #retrieves the device list in /dev (Linux)
vfs.dir.get["C:\\Users\\ADMINI~1\\AppData\\Local\\Temp"] #retrieves the file list in a temporary directory
vfs.dir.size[dir,<regex incl>,<regex excl>,<mode>,<max depth>,<regex excl dir>]
```

 The directory size (in bytes).
 Return value: *Integer*.
 [Supported platforms](#): Linux. The item may work on other UNIX-like platforms.

Parameters:

- **dir** - the absolute path to directory;
- **regex incl** - a regular **expression** describing the name pattern of the entity (file, directory, symbolic link) to include; include all if empty (default value);
- **regex excl** - a regular **expression** describing the name pattern of the entity (file, directory, symbolic link) to exclude; don't exclude any if empty (default value);
- **mode** - possible values: *apparent* (default) - gets apparent file sizes rather than disk usage (acts as `du -sb dir`), *disk* - gets disk usage (acts as `du -s -B1 dir`). Unlike the `du` command, the `vfs.dir.size` item takes hidden files in account when calculating the directory size (acts as `du -sb .[^.]* *` within `dir`).
- **max depth** - the maximum depth of subdirectories to traverse: **-1** (default) - unlimited, **0** - no descending into subdirectories.
- **regex excl dir** - a regular **expression** describing the name pattern of the directory to exclude. All content of the directory will be excluded (in contrast to `regex excl`)

Comments:

- Only directories with at least the read permission for *zabbix* user are calculated. For directories with read permission only, the size of the directory itself is calculated. Directories with read & execute permissions are calculated including contents.
- With large directories or slow drives this item may time out due to the Timeout setting in **agent** and **server/proxy** configuration files. Increase the timeout values as necessary.
- The file size limit depends on **large file support**.

Examples:

```
vfs.dir.size[/tmp,log] #calculates the size of all files in /tmp containing 'log' in their names
vfs.dir.size[/tmp,log,^.+\.old$] #calculates the size of all files in /tmp containing 'log' in their names
vfs.file.cksum[file,<mode>]
```

 The file checksum, calculated by the UNIX cksum algorithm.
 Return value: *Integer* - with mode as *crc32*, *String* - with mode as *md5*, *sha256*.
 See **supported platforms**.

Parameters:

- **file** - the full path to file;
- **mode** - *crc32* (default), *md5*, or *sha256*.

The file size limit depends on **large file support**.

Example:

```
vfs.file.cksum[/etc/passwd]
```

Examples of returned values (crc32/md5/sha256 respectively):

```
675436101
9845acf68b73991eb7fd7ee0ded23c44
ae67546e4aac995e5c921042d0cf0f1f7147703aa42bfbfb65404b30f238f2dc
```

```
vfs.file.contents[file,<encoding>]
```

 Retrieving the contents of a file⁷.
 Return value: *Text*.
 See **supported platforms**.

Parameters:

- **file** - the full path to file;
- **encoding** - the code page **identifier**.

Comments:

- The return value is limited to 16MB (including trailing whitespace that is truncated); **database limits** also apply;
- An empty string is returned if the file is empty or contains LF/CR characters only;
- The byte order mark (BOM) is excluded from the output.

Example:

```
vfs.file.contents[/etc/passwd]
```

```
vfs.file.exists[file,<types incl>,<types excl>]
```

 Checks if the file exists.
 Return value: 0 - not found; 1 - file of the specified type exists.
 See **supported platforms**.

Parameters:

- **file** - the full path to file;

- **types incl** - the list of file types to include, possible values: *file* (regular file, default (if types_excl is not set)), *dir* (directory), *sym* (symbolic link), *sock* (socket), *bdev* (block device), *cdev* (character device), *fifo* (FIFO), *dev* (synonymous with "bdev,cdev"), *all* (all mentioned types, default if types_excl is set).
- **types excl** - the list of file types to exclude, see types_incl for possible values (by default no types are excluded)

Comments:

- Multiple types must be separated with a comma and the entire set enclosed in quotes "";
- If the same type is in both <types_incl> and <types_excl>, files of this type are excluded;
- The file size limit depends on [large file support](#).

Examples:

```
vfs.file.exists[/tmp/application.pid]
vfs.file.exists[/tmp/application.pid,"file,dir,sym"]
vfs.file.exists[/tmp/application_dir,dir]
vfs.file.get[file]
```

 Returns information about a file.
 Return value: *JSON object*.
 See [supported platforms](#).

Parameter:

- **file** - the full path to file

Comments:

- Supported file types on UNIX-like systems: regular file, directory, symbolic link, socket, block device, character device, FIFO.
- The file size limit depends on [large file support](#).

Example:

```
vfs.file.get[/etc/passwd] #return a JSON with information about the /etc/passwd file (type, user, permissions)
vfs.file.md5sum[file]
```

 The MD5 checksum of file.
 Return value: Character string (MD5 hash of the file).
 See [supported platforms](#).

Parameter:

- **file** - the full path to file

The file size limit depends on [large file support](#).

Example:

```
vfs.file.md5sum[/usr/local/etc/zabbix_agentd.conf]
```

Example of returned value:

```
b5052dec577e0fffd622d6ddc017e82
```

```
vfs.file.owner[file,<ownertype>,<resulttype>]
```

 Retrieves the owner of a file.
 Return value: *String*.
 See [supported platforms](#).

Parameters:

- **file** - the full path to file;
- **ownertype** - *user* (default) or *group* (Unix only);
- **resulttype** - *name* (default) or *id*; for id - return uid/gid on Unix, SID on Windows.

The file size limit depends on [large file support](#).

Examples:

```
vfs.file.owner[/tmp/zabbix_server.log] #return the file owner of /tmp/zabbix_server.log
vfs.file.owner[/tmp/zabbix_server.log,,id] #return the file owner ID of /tmp/zabbix_server.log
vfs.file.permissions[file]
```

 Return a 4-digit string containing the octal number with UNIX permissions.
 Return value: *String*.
 [Supported platforms](#): Linux. The item may work on other UNIX-like platforms.

Parameters:

- **file** - the full path to file

The file size limit depends on [large file support](#).

Example:

```
vfs.file.permissions[/etc/passwd] #return permissions of /etc/passwd, for example, '0644'
```

```
vfs.file.regexp[file,regexp,<encoding>,<start line>,<end line>,<output>]
```

 Retrieve a string in the file⁷.
 Return value: The line containing the matched string, or as specified by the optional output parameter.
 See [supported platforms](#).

Parameters:

- **file** - the full path to file;
- **regexp** - a regular [expression](#) describing the required pattern;
- **encoding** - the code page [identifier](#);
- **start line** - the number of the first line to search (first line of file by default);
- **end line** - the number of the last line to search (last line of file by default);
- **output** - an optional output formatting template. The `\0` escape sequence is replaced with the matched part of text (from the first character where match begins until the character where match ends) while an `\N` (where N=1...9) escape sequence is replaced with Nth matched group (or an empty string if the N exceeds the number of captured groups).

Comments:

- The file size limit depends on [large file support](#).
- Only the first matching line is returned;
- An empty string is returned if no line matched the expression;
- The byte order mark (BOM) is excluded from the output;
- Content extraction using the output parameter takes place on the agent.

Examples:

```
vfs.file.regexp[/etc/passwd,zabbix]
```

```
vfs.file.regexp[/path/to/some/file,"([0-9]+)$",,3,5,\1]
```

```
vfs.file.regexp[/etc/passwd,"^zabbix:([0-9]+)",,,\1] → getting the ID of user *zabbix*
```

```
vfs.file.regmatch[file,regexp,<encoding>,<start line>,<end line>]
```

 Find a string in the file⁷.
 Return values: 0 - match not found; 1 - found.
 See [supported platforms](#).

Parameters:

- **file** - the full path to file;
- **regexp** - a regular [expression](#) describing the required pattern;
- **encoding** - the code page [identifier](#);
- **start line** - the number of the first line to search (first line of file by default);
- **end line** - the number of the last line to search (last line of file by default).

Comments:

- The file size limit depends on [large file support](#).
- The byte order mark (BOM) is ignored.

Example:

```
vfs.file.regmatch[/var/log/app.log,error]
```

```
vfs.file.size[file,<mode>]
```

 The file size (in bytes).
 Return value: *Integer*.
 See [supported platforms](#).

Parameters:

- **file** - the full path to file;
- **mode** - possible values: *bytes* (default) or *lines* (empty lines are counted, too).

Comments:

- The file must have read permissions for user *zabbix*;
- The file size limit depends on [large file support](#).

Example:

```
vfs.file.size[/var/log/syslog]
```

`vfs.file.time[file,<mode>]`

 The file time information.
 Return value: *Integer* (Unix timestamp).
 See [supported platforms](#).

Parameters:

- **file** - the full path to file;
- **mode** - possible values:
modify (default) - the last time of modifying file content,
access - the last time of reading file,
change - the last time of changing file properties

The file size limit depends on [large file support](#).

Example:

```
vfs.file.time[/etc/passwd,modify]
```

`vfs.fs.discovery`

 The list of mounted filesystems with their type and mount options. Used for low-level discovery.
 Return value: *JSON object*.
 [Supported platforms](#): Linux, FreeBSD, Solaris, HP-UX, AIX, MacOS X, OpenBSD, NetBSD.

`vfs.fs.get`

 The list of mounted filesystems with their type, available disk space, inode statistics and mount options. Can be used for low-level discovery.
 Return value: *JSON object*.
 [Supported platforms](#): Linux, FreeBSD, Solaris, HP-UX, AIX, MacOS X, OpenBSD, NetBSD.

Comments:

- File systems with the inode count equal to zero, which can be the case for file systems with dynamic inodes (e.g. btrfs), are also reported;
- See also: [Discovery of mounted filesystems](#).

`vfs.fs.inode[fs,<mode>]`

 The number or percentage of inodes.
 Return value: *Integer* - for number; *Float* - for percentage.
 See [supported platforms](#).

Parameters:

- **fs** - the filesystem;
- **mode** - possible values: *total* (default), *free*, *used*, *pfree* (free, percentage), or *pused* (used, percentage).

If the inode count equals zero, which can be the case for file systems with dynamic inodes (e.g. btrfs), the *pfree/pused* values will be reported as "100" and "0" respectively.

Example:

```
vfs.fs.inode[/,pfree]
```

`vfs.fs.size[fs,<mode>]`

 The disk space in bytes or in percentage from total.
 Return value: *Integer* - for bytes; *Float* - for percentage.
 See [supported platforms](#).

Parameters:

- **fs** - the filesystem;
- **mode** - possible values: *total* (default), *free*, *used*, *pfree* (free, percentage), or *pused* (used, percentage).

Comments:

- If the filesystem is not mounted, returns the size of a local filesystem where the mount point is located;
- The reserved space of a file system is taken into account and not included when using the *free* mode.

Example:

```
vfs.fs.size[/tmp,free]
```

`vm.memory.size[<mode>]`

 The memory size in bytes or in percentage from total.
 Return value: *Integer* - for bytes; *Float* - for percentage.
 See [supported platforms](#).

Parameter:

- **mode** - possible values: *total* (default), *active*, *anon*, *buffers*, *cached*, *exec*, *file*, *free*, *inactive*, *pinned*, *shared*, *slab*, *wired*, *used*, *pused* (used, percentage), *available*, or *pavailable* (available, percentage).

Comments:

- This item accepts three categories of parameters:
1) *total* - total amount of memory
2) platform-specific memory types: *active*, *anon*, *buffers*, *cached*, *exec*, *file*, *free*, *inactive*, *pinned*, *shared*, *slab*, *wired*
3) user-level estimates on how much memory is used and available: *used*, *pused*, *available*, *pavailable*
- The *active* mode parameter is supported only on FreeBSD, HP-UX, MacOS X, OpenBSD, NetBSD;
- The *anon*, *exec*, *file* mode parameters are supported only on NetBSD;
- The *buffers* mode parameter is supported only on Linux, FreeBSD, OpenBSD, NetBSD;
- The *cached* mode parameter is supported only on Linux, FreeBSD, AIX, OpenBSD, NetBSD;
- The *inactive*, *wired* mode parameters are supported only on FreeBSD, MacOS X, OpenBSD, NetBSD;
- The *pinned* mode parameter is supported only on AIX;
- The *shared* mode parameter is supported only on Linux 2.4, FreeBSD, OpenBSD, NetBSD;
- See also [additional details](#) for this item.

Example:

```
vm.memory.size[pavailable]
```

```
web.page.get[host,<path>,<port>]
```

 Get the content of a web page.
 Return value: Web page source as text (including headers).
 See [supported platforms](#).

Parameters:

- **host** - the hostname or URL (as `scheme://host:port/path`, where only *host* is mandatory). Allowed URL schemes: *http*, *https*⁴. A missing scheme will be treated as *http*. If a URL is specified *path* and *port* must be empty. Specifying user name/password when connecting to servers that require authentication, for example: `http://user:password@www.example.com` is only possible with cURL support⁴. [Punycode](#) is supported in hostnames.
- **path** - the path to an HTML document (default is */*);
- **port** - the port number (default is 80 for HTTP)

Comments:

- This item turns unsupported if the resource specified in *host* does not exist or is unavailable;
- *host* can be a hostname, domain name, IPv4 or IPv6 address. But for IPv6 address Zabbix agent must be compiled with IPv6 support enabled.

Examples:

```
web.page.get[www.example.com,index.php,80]
```

```
web.page.get[https://www.example.com]
```

```
web.page.get[https://blog.example.com/?s=zabbix]
```

```
web.page.get[localhost:80]
```

```
web.page.get["[:1]/server-status"]
```

```
web.page.perf[host,<path>,<port>]
```

 The loading time of a full web page (in seconds).
 Return value: *Float*.
 See [supported platforms](#).

Parameters:

- **host** - the hostname or URL (as `scheme://host:port/path`, where only *host* is mandatory). Allowed URL schemes: *http*, *https*⁴. A missing scheme will be treated as *http*. If a URL is specified *path* and *port* must be empty. Specifying user name/password when connecting to servers that require authentication, for example: `http://user:password@www.example.com` is only possible with cURL support⁴. [Punycode](#) is supported in hostnames.
- **path** - the path to an HTML document (default is */*);
- **port** - the port number (default is 80 for HTTP)

Comments:

- This item turns unsupported if the resource specified in *host* does not exist or is unavailable;
- *host* can be a hostname, domain name, IPv4 or IPv6 address. But for IPv6 address Zabbix agent must be compiled with IPv6 support enabled.

Examples:

```
web.page.perf[www.example.com,index.php,80]
```

```
web.page.perf[https://www.example.com]
```

```
web.page.regex[host,<path>,<port>,regexp,<length>,<output>]
```

 Find a string on the web page.
 Return value: The matched string, or as specified by the optional output parameter.
 See [supported platforms](#).

Parameters:

- **host** - the hostname or URL (as `scheme://host:port/path`, where only *host* is mandatory). Allowed URL schemes: *http*, *https*⁴. A missing scheme will be treated as *http*. If a URL is specified *path* and *port* must be empty. Specifying user name/password when connecting to servers that require authentication, for example: `http://user:password@www.example.com` is only possible with cURL support⁴. Punycode is supported in hostnames.
- **path** - the path to an HTML document (default is `/`);
- **port** - the port number (default is 80 for HTTP)
- **regexp** - a regular [expression](#) describing the required pattern;
- **length** - the maximum number of characters to return;
- **output** - an optional output formatting template. The `\0` escape sequence is replaced with the matched part of text (from the first character where match begins until the character where match ends) while an `\N` (where `N=1...9`) escape sequence is replaced with Nth matched group (or an empty string if the `N` exceeds the number of captured groups).

Comments:

- This item turns unsupported if the resource specified in *host* does not exist or is unavailable;
- *host* can be a hostname, domain name, IPv4 or IPv6 address. But for IPv6 address Zabbix agent must be compiled with IPv6 support enabled.
- Content extraction using the *output* parameter takes place on the agent.

Examples:

```
web.page.regexp[www.example.com,index.php,80,OK,2]
web.page.regexp[https://www.example.com,,,OK,2] |
```

agent.hostmetadata

 The agent host metadata.
 Return value: *String*.
 See [supported platforms](#).

Returns the value of [HostMetadata](#) or [HostMetadataItem](#) parameters, or empty string if none are defined.

agent.hostname

 The agent host name.
 Return value: *String*.
 See [supported platforms](#).

Returns:

- As passive check - the name of the first host listed in the [Hostname](#) parameter of the agent configuration file;
- As active check - the name of the current hostname.

agent.ping

 The agent availability check.
 Return value: Nothing - unavailable; 1 - available.
 See [supported platforms](#).

Use the **nodata()** trigger function to check for host unavailability.

agent.variant

 The variant of Zabbix agent (Zabbix agent or Zabbix agent 2).
 Return value: 1 - Zabbix agent; 2 - Zabbix agent 2.
 See [supported platforms](#).

agent.version

 The version of Zabbix agent.
 Return value: *String*.
 See [supported platforms](#).

Example of returned value:

6.0.3

zabbix.stats[<ip>,<port>]

 Returns a set of Zabbix server or proxy internal metrics remotely.
 Return value: *JSON object*.
 See [supported platforms](#).

Parameters:

- **ip** - the IP/DNS/network mask list of servers/proxies to be remotely queried (default is 127.0.0.1);
- **port** - the port of server/proxy to be remotely queried (default is 10051)

Comments:

- A selected set of internal metrics is returned by this item. For details, see [Remote monitoring of Zabbix stats](#);

- Note that the stats request will only be accepted from the addresses listed in the 'StatsAllowedIP' [server/proxy](#) parameter on the target instance.

`zabbix.stats[<ip>,<port>,queue,<from>,<to>]`

 Returns the number of monitored items in the queue which are delayed on Zabbix server or proxy remotely.
 Return value: *JSON object*.
 See [supported platforms](#).

Parameters:

- **ip** - the IP/DNS/network mask list of servers/proxies to be remotely queried (default is 127.0.0.1);
- **port** - the port of server/proxy to be remotely queried (default is 10051)
- **queue** - constant (to be used as is)
- **from** - delayed by at least (default is 6 seconds)
- **to** - delayed by at most (default is infinity)

Note that the stats request will only be accepted from the addresses listed in the 'StatsAllowedIP' [server/proxy](#) parameter on the target instance.

Footnotes

¹ A Linux-specific note. Zabbix agent must have read-only access to filesystem `/proc`. Kernel patches from www.grsecurity.org limit access rights of non-privileged users.

² `vfs.dev.read[]`, `vfs.dev.write[]`: Zabbix agent will terminate "stale" device connections if the item values are not accessed for more than 3 hours. This may happen if a system has devices with dynamically changing paths or if a device gets manually removed. Note also that these items, if using an update interval of 3 hours or more, will always return '0'.

³ `vfs.dev.read[]`, `vfs.dev.write[]`: If default *all* is used for the first parameter then the key will return summary statistics, including all block devices like `sda`, `sdb`, and their partitions (`sda1`, `sda2`, `sdb3`...) and multiple devices (MD raid) based on those block devices/partitions and logical volumes (LVM) based on those block devices/partitions. In such cases returned values should be considered only as relative value (dynamic in time) but not as absolute values.

⁴ SSL (HTTPS) is supported only if agent is compiled with cURL support. Otherwise the item will turn unsupported.

⁵ The bytes and errors values are not supported for loopback interfaces on Solaris systems up to and including Solaris 10 6/06 as byte, error and utilization statistics are not stored and/or reported by the kernel. However, if you're monitoring a Solaris system via `net-snmp`, values may be returned as `net-snmp` carries legacy code from the `cmu-snmp` dated as old as 1997 that, upon failing to read byte values from the interface statistics returns the packet counter (which does exist on loopback interfaces) multiplied by an arbitrary value of 308. This makes the assumption that the average length of a packet is 308 octets, which is a very rough estimation as the MTU limit on Solaris systems for loopback interfaces is 8892 bytes. These values should not be assumed to be correct or even closely accurate. They are guestimates. The Zabbix agent does not do any guess work, but `net-snmp` will return a value for these fields.

⁶ The command line on Solaris, obtained from `/proc/pid/psinfo`, is limited to 80 bytes and contains the command line as it was when the process was started.

⁷ `vfs.file.contents[]`, `vfs.file.regex[]`, `vfs.file.regmatch[]` items can be used for retrieving file contents. If you want to restrict access to specific files with sensitive information, run Zabbix agent under a user that has no access permissions to viewing these files.

Usage with command-line utilities

Note that when testing or using item keys with `zabbix_agentd` or `zabbix_get` from the command line you should consider shell syntax too.

For example, if a certain parameter of the key has to be enclosed in double quotes you have to explicitly escape double quotes, otherwise they will be trimmed by the shell as special characters and will not be passed to the Zabbix utility.

Examples:

```
zabbix_agentd -t 'vfs.dir.count[/var/log,,,"file,dir",,0]'
```

```
zabbix_agentd -t 'vfs.dir.count[/var/log,,,\"file,dir\",,0]'
```

Encoding settings

To make sure that the acquired data are not corrupted you may specify the correct encoding for processing the check (e.g. 'vfs.file.contents') in the `encoding` parameter. The list of supported encodings (code page identifiers) may be found in documentation for [libiconv](#) (GNU Project) or in Microsoft Windows SDK documentation for "Code Page Identifiers".

If no encoding is specified in the `encoding` parameter the following resolution strategies are applied:

- If encoding is not specified (or is an empty string) it is assumed to be UTF-8, the data is processed "as-is";

- BOM analysis - applicable for items 'vfs.file.contents', 'vfs.file.regexp', 'vfs.file.regmatch'. An attempt is made to determine the correct encoding by using the byte order mark (BOM) at the beginning of the file. If BOM is not present - standard resolution (see above) is applied instead.

Troubleshooting agent items

In case of passive checks, to prevent that item does not get any value because the server request to the agent times out first, the following should be noted:

- Where agent version is older than server version, the *Timeout* value in the **item configuration** (or **global timeout**) may need to be higher than the *Timeout* value in the agent **configuration file**.
- Where agent version is newer than server version, the *Timeout* value in the server **configuration file** may need to be higher than the *Timeout* value in the agent **configuration file**.

1 Zabbix agent 2

Zabbix agent 2 supports all item keys supported for Zabbix agent on **Unix** and **Windows**. This page provides details on the additional item keys, which you can use with Zabbix agent 2 only, grouped by the plugin they belong to.

The item keys are listed without parameters and additional information. Click on the item key to see the full details.

| Item key | Description | Plugin |
|---|--|-----------|
| ceph.df.details | The cluster's data usage and distribution among pools. | Ceph |
| ceph.osd.stats | Aggregated and per OSD statistics. | |
| ceph.osd.discovery | The list of discovered OSDs. | |
| ceph.osd.dump | The usage thresholds and statuses of OSDs. | |
| ceph.ping | Tests whether a connection to Ceph can be established. | |
| ceph.pool.discovery | The list of discovered pools. | |
| ceph.status | The overall cluster's status. | |
| docker.container_info | Low-level information about a container. | Docker |
| docker.container_stats | The container resource usage statistics. | |
| docker.containers | Returns the list of containers. | |
| docker.containers.discovery | Returns the list of containers. Used for low-level discovery. | |
| docker.data.usage | Information about the current data usage. | |
| docker.images | Returns the list of images. | |
| docker.images.discovery | Returns the list of images. Used for low-level discovery. | |
| docker.info | The system information. | |
| docker.ping | Test if the Docker daemon is alive or not. | |
| ember.get | Returns the result of the required device. | Ember+ |
| memcached.ping | Test if a connection is alive or not. | |
| memcached.stats | Gets the output of the STATS command. | Memcached |
| mongodb.collection.stats | Returns a variety of storage statistics for a given collection. | |
| mongodb.collections.discovery | Returns a list of discovered collections. | MongoDB |
| mongodb.collections.usage | Returns the usage statistics for collections. | |
| mongodb.connpool.stats | Returns information regarding the open outgoing connections from the current database instance to other members of the sharded cluster or replica set. | |
| mongodb.db.stats | Returns the statistics reflecting a given database system state. | |
| mongodb.db.discovery | Returns a list of discovered databases. | |
| mongodb.jumbo_chunks.count | Returns the count of jumbo chunks. | |
| mongodb.oplog.stats | Returns the status of the replica set, using data polled from the oplog. | |
| mongodb.ping | Test if a connection is alive or not. | |
| mongodb.rs.config | Returns the current configuration of the replica set. | |
| mongodb.rs.status | Returns the replica set status from the point of view of the member where the method is run. | |
| mongodb.server.status | Returns the database state. | MQTT |
| mongodb.sh.discovery | Returns the list of discovered shards present in the cluster. | |
| mongodb.version | Returns the database server version. | |
| mqtt.get | Subscribes to a specific topic or topics (with wildcards) of the provided broker and waits for publications. | |
| mssql.availability.group.get | Returns availability groups. | MSSQL |
| mssql.custom.query | Returns the result of a custom query. | |
| mssql.db.get | Returns all available MSSQL databases. | |
| mssql.job.status.get | Returns the status of jobs. | |

| Item key | Description | Plugin |
|------------------------------------|--|--------------------------|
| mssql.last.backup.get | Returns the last backup time for all databases. | MySQL |
| mssql.local.db.get | Returns databases that are participating in an Always On availability group and replica (primary or secondary) and are located on the server that the connection was established to. | |
| mssql.mirroring.get | Returns mirroring info. | |
| mssql.nonlocal.db.get | Returns databases that are participating in an Always On availability group and replica (primary or secondary) located on other servers (the database is not local to the SQL Server instance that the connection was established to). | |
| mssql.perfcounter.get | Returns the performance counters. | |
| mssql.ping | Test if a connection is alive or not. | |
| mssql.quorum.get | Returns the quorum info. | |
| mssql.quorum.member.get | Returns the quorum members. | |
| mssql.replica.get | Returns the replicas. | |
| mssql.version | Returns the MSSQL version. | |
| mysql.custom.query | Returns the result of a custom query. | |
| mysql.db.discovery | Returns the list of MySQL databases. | |
| mysql.db.size | The database size in bytes. | |
| mysql.get_status_variables | Values of the global status variables. | |
| mysql.ping | Test if a connection is alive or not. | |
| mysql.replication.discovery | Returns the list of MySQL replications. | |
| mysql.replication.get_slave_status | The replication status. | |
| mysql.version | The MySQL version. | |
| net.dns.get | Performs a DNS query and returns detailed DNS record information. | Network NVIDIA GPU |
| nvml.device.count | The number of GPU devices. | |
| nvml.device.decoder.utilization | GPU device decoder utilization. | |
| nvml.device.ecc.mode | GPU device ECC mode. | |
| nvml.device.encoder.stats | GPU device encoder statistics. | |
| nvml.device.encoder.utilization | GPU device encoder utilization. | |
| nvml.device.energy.consumption | GPU device energy consumption. | |
| nvml.device.errors.memory | GPU device ECC memory error information. | |
| nvml.device.errors.register | GPU device ECC register error information. | |
| nvml.device.fan.speed.avg | GPU device fan speed average. | |
| nvml.device.get | Discovered GPUs with UUID and name. | |
| nvml.device.graphics.frequency | GPU device graphics clock speed. | |
| nvml.device.memory.bar1 | GPU device BAR1 memory information. | |
| nvml.device.memory.fb.get | GPU device framebuffer memory information. | |
| nvml.device.memory.frequency | GPU device memory clock speed. | |
| nvml.device.pci.utilization | GPU device PCI utilization. | |
| nvml.device.performance.state | GPU device performance state. | |
| nvml.device.power.limit | GPU device power limit. | |
| nvml.device.power.usage | GPU device power usage. | |
| nvml.device.serial | GPU device serial number. | |
| nvml.device.sm.frequency | GPU device streaming multiprocessor clock speed. | |
| nvml.device.temperature | GPU device temperature. | |
| nvml.device.utilization | GPU device utilization statistics. | |
| nvml.device.video.frequency | GPU device video clock speed. | |
| nvml.system.driver.version | The NVIDIA driver version. | |
| nvml.version | The NVML library version. | |
| oracle.diskgroups.stats | Returns the Automatic Storage Management (ASM) disk groups statistics. | Oracle |
| oracle.diskgroups.discovery | Returns the list of ASM disk groups. | |
| oracle.archive.info | The archive logs statistics. | |
| oracle.cdb.info | The Container Databases (CDBs) information. | |
| oracle.custom.query | The result of a custom query. | |
| oracle.datafiles.stats | Returns the data files statistics. | |
| oracle.db.discovery | Returns the list of databases. | |
| oracle.fra.stats | Returns the Fast Recovery Area (FRA) statistics. | |
| oracle.instance.info | The instance statistics. | |
| oracle.pdb.info | The Pluggable Databases (PDBs) information. | |
| oracle.pdb.discovery | Returns the list of PDBs. | |
| oracle.pga.stats | Returns the Program Global Area (PGA) statistics. | |

| Item key | Description | Plugin |
|-------------------------------------|--|------------------|
| oracle.ping | Test whether a connection to Oracle can be established. | PostgreSQL |
| oracle.proc.stats | Returns the processes statistics. | |
| oracle.redolog.info | The log file information from the control file. | |
| oracle.sga.stats | Returns the System Global Area (SGA) statistics. | |
| oracle.sessions.stats | Returns the sessions statistics. | |
| oracle.sys.metrics | Returns a set of system metric values. | |
| oracle.sys.params | Returns a set of system parameter values. | |
| oracle.ts.stats | Returns the tablespaces statistics. | |
| oracle.ts.discovery | Returns a list of tablespaces. | |
| oracle.user.info | Returns Oracle user information. | |
| oracle.version | Returns the database server version. | |
| pgsql.autovacuum.count | The number of autovacuum workers. | |
| pgsql.archive | The information about archived files. | |
| pgsql.bgwriter | The combined number of checkpoints for the database cluster, broken down by checkpoint type. | |
| pgsql.cache.hit | The PostgreSQL buffer cache hit rate. | |
| pgsql.connections | Returns connections by type. | |
| pgsql.custom.query | Returns the result of a custom query. | |
| pgsql.db.age | The age of the oldest FrozenXID of the database. | |
| pgsql.db.bloating_tables | The number of bloating tables per database. | |
| pgsql.db.discovery | The list of PostgreSQL databases. | |
| pgsql.db.size | The database size in bytes. | |
| pgsql.dbstat | Collects the statistics per database. | |
| pgsql.dbstat.sum | The summarized data for all databases in a cluster. | |
| pgsql.locks | The information about granted locks per database. | |
| pgsql.oldest.xid | The age of the oldest XID. | |
| pgsql.ping | Test if a connection is alive or not. | |
| pgsql.queries | Query metrics by execution time. | |
| pgsql.replication.count | The number of standby servers. | |
| pgsql.replication.process | The flush lag, write lag and replay lag per each sender process. | |
| pgsql.replication.process.discovery | The replication process name discovery. | |
| pgsql.replication.recovery | The recovery status. | |
| pgsql.replication.status | The status of replication. | |
| pgsql.replication_lag.b | The replication lag in bytes. | |
| pgsql.replication_lag.sec | The replication lag in seconds. | |
| pgsql.uptime | The PostgreSQL uptime in milliseconds. | |
| pgsql.version | Returns PostgreSQL version. | |
| pgsql.wal.stat | The WAL statistics. | |
| redis.config | Gets the configuration parameters of a Redis instance that match the pattern. | Redis |
| redis.info | Gets the output of the INFO command. | |
| redis.ping | Test if a connection is alive or not. | |
| redis.slowlog.count | The number of slow log entries since Redis was started. | S.M.A.R.T. |
| smart.attribute.discovery | Returns a list of S.M.A.R.T. device attributes. | |
| smart.disk.discovery | Returns a list of S.M.A.R.T. devices. | |
| smart.disk.get | Returns all available properties of S.M.A.R.T. devices. | Systemd |
| systemd.unit.get | Returns all properties of a systemd unit. | |
| systemd.unit.info | Systemd unit information. | |
| systemd.unit.discovery | The list of systemd units and their details. | Web certificates |
| web.certificate.get | Validates the certificates and returns certificate details. | |

Item key details

Parameters without angle brackets are mandatory. Parameters marked with angle brackets < > are optional.

ceph.df.details[connString,<user>,<apikey>]

 The cluster's data usage and distribution among pools.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

ceph.osd.stats[connString,<user>,<apikey>]

 Aggregated and per OSD statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

ceph.osd.discovery[connString,<user>,<apikey>]

 The list of discovered OSDs. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

ceph.osd.dump[connString,<user>,<apikey>]

 The usage thresholds and statuses of OSDs.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

ceph.ping[connString,<user>,<apikey>]

 Tests whether a connection to Ceph can be established.
 Return value: *0* - connection is broken (if there is any error presented including AUTH and configuration issues); *1* - connection is successful.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

ceph.pool.discovery[connString,<user>,<apikey>]

 The list of discovered pools. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

ceph.status[connString,<user>,<apikey>]

 The overall cluster's status.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Ceph login credentials.

docker.container_info[<ID>,<info>]

 Low-level information about a container.
 Return value: The output of the [ContainerInspect](#) API call serialized as JSON.

Parameters:

- **ID** - the ID or name of the container;

- **info** - the amount of information returned. Supported values: *short* (default) or *full*.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.container_stats[<ID>]

 The container resource usage statistics.
 Return value: The output of the [ContainerStats](#) API call and CPU usage percentage serialized as JSON.

Parameter:

- **ID** - the ID or name of the container.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.containers

 The list of containers.
 Return value: The output of the [ContainerList](#) API call serialized as JSON.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.containers.discovery[<options>]

 Returns the list of containers. Used for [low-level discovery](#).
 Return value: *JSON object*.

Parameter:

- **options** - specify whether all or only running containers should be discovered. Supported values: *true* - return all containers; *false* - return only running containers (default).

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.data.usage

 Information about the current data usage.
 Return value: The output of the [SystemDataUsage](#) API call serialized as JSON.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.images

 Returns the list of images.
 Return value: The output of the [ImageList](#) API call serialized as JSON.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.images.discovery

 Returns the list of images. Used for [low-level discovery](#).
 Return value: *JSON object*.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.info

 The system information.
 Return value: The output of the [SystemInfo](#) API call serialized as JSON.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

docker.ping

 Test if the Docker daemon is alive or not.
 Return value: *1* - the connection is alive; *0* - the connection is broken.

The Agent 2 user ('zabbix') must be added to the 'docker' [group](#) for sufficient privileges. Otherwise the check will fail.

ember.get[<uri>,<path>]

 Returns the result of the required device.
 Return value: *JSON object*.

Parameters:

- **uri** - Ember+ device URI. Default: 127.0.0.1:9998;

- **path** - OID path to device. Empty by default, returns root collection data.

memcached.ping[connString,<user>,<password>]

 Test if a connection is alive or not.
 Return value: *1* - the connection is alive; *0* - the connection is broken (if there is any error presented including AUTH and configuration issues).

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Memcached login credentials.

memcached.stats[connString,<user>,<password>,<type>]

 Gets the output of the STATS command.
 Return value: *JSON* - the output is serialized as JSON.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the Memcached login credentials;

- **type** - stat type to be returned: *items*, *sizes*, *slabs* or *settings* (empty by default, returns general statistics).

mongodb.collection.stats[connString,<user>,<password>,<database>,collection]

 Returns a variety of storage statistics for a given collection.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials;

- **database** - the database name (default: admin);

- **collection** - the collection name.

mongodb.collections.discovery[connString,<user>,<password>]

 Returns a list of discovered collections. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.collections.usage[connString,<user>,<password>]

 Returns the usage statistics for collections.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.connpool.stats[connString,<user>,<password>]

 Returns information regarding the open outgoing connections from the current database instance to other members of the sharded cluster or replica set.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials;

- **database** - the database name (default: admin);

- **collection** - the collection name.

mongodb.db.stats[connString,<user>,<password>,<database>]

 Returns the statistics reflecting a given database system state.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials;

- **database** - the database name (default: admin).

mongodb.db.discovery[connString,<user>,<password>]

 Returns a list of discovered databases. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.jumbo_chunks.count[connString,<user>,<password>]

 Returns the count of jumbo chunks.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.oplog.stats[connString,<user>,<password>]

 Returns the status of the replica set, using data polled from the oplog.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.ping[connString,<user>,<password>]

 Test if a connection is alive or not.
 Return value: *1* - the connection is alive; *0* - the connection is broken (if there is any error presented including AUTH and configuration issues).

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.rs.config[connString,<user>,<password>]

 Returns the current configuration of the replica set.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.rs.status[connString,<user>,<password>]

 Returns the replica set status from the point of view of the member where the method is run.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.server.status[connString,<user>,<password>]

 Returns the database state.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.sh.discovery[connString,<user>,<password>]

 Returns the list of discovered shards present in the cluster.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mongodb.version[connString,<user>,<password>]

 Returns the database server version.
 Return value: *String*.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MongoDB login credentials.

mqtt.get[<broker url>,topic,<user>,<password>]

 Subscribes to a specific topic or topics (with wildcards) of the provided broker and waits for publications.
 Return value: Depending on topic content. If wildcards are used, returns topic content as JSON.

Parameters:

- **broker url** - the MQTT broker URL in the format protocol://host:port without query parameters (supported protocols: tcp, ssl, ws). If no value is specified, the agent will use tcp://localhost:1883. If a protocol or port are omitted, default protocol (tcp) or port (1883) will be used;

- **topic** - the MQTT topic (mandatory). Wildcards (+,#) are supported;

- **user, password** - the authentication credentials (if required).

Comments:

- The item must be configured as an **active check** ('Zabbix agent (active)' item type);
- TLS encryption certificates can be used by saving them into a default location (e.g. /etc/ssl/certs/ directory for Ubuntu). For TLS, use the **tls://** scheme.

mssql.availability.group.get[URI,<user>,<password>]

 Returns availability groups.
 Return value: *JSON object*.

Parameters:

- **URI** - MSSQL server URI (the only supported schema is `sqlserver://`). Embedded credentials will be ignored. It is possible to specify an instance name as part of the URI, i.e.: `sqlserver://localhost/InstanceName` (no port). If port is specified, the instance name is ignored;

- **user, password** - username, password to send to protected MSSQL server.

For more information see the [MSSQL plugin](#) readme.

`mssql.custom.query[URI,<user>,<password>,queryName,<args...>]`

 Returns the result of a custom query.
 Return value: *JSON object*.

Parameters:

- **URI** - MSSQL server URI (the only supported schema is `sqlserver://`). Embedded credentials will be ignored. It is possible to specify an instance name as part of the URI, i.e.: `sqlserver://localhost/InstanceName` (no port). If port is specified, the instance name is ignored;

- **user, password** - username, password to send to protected MSSQL server;

- **queryName** - name of a custom query configured in `Plugins.MSSQL.CustomQueriesDir` without the `.sql` extension;

- **args** - one or several comma-separated arguments to pass to a query.

For more information see the [MSSQL plugin](#) readme.

`mssql.db.get`

 Returns all available MSSQL databases.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.job.status.get`

 Returns the status of jobs.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.last.backup.get`

 Returns the last backup time for all databases.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.local.db.get`

 Returns databases that are participating in an Always On availability group and replica (primary or secondary) and are located on the server that the connection was established to.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.mirroring.get`

 Returns mirroring info.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.nonlocal.db.get`

 Returns databases that are participating in an Always On availability group and replica (primary or secondary) located on other servers (the database is not local to the SQL Server instance that the connection was established to).
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.perfcounter.get`

 Returns the performance counters.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

`mssql.ping`

 Ping the database. Test if connection is correctly configured.
 Return value: *1 - alive, 0 - not alive*.

For more information see the [MSSQL plugin](#) readme.

`mssql.quorum.get`

 Returns the quorum info.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

mssql.quorum.member.get

 Returns the quorum members.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

mssql.replica.get

 Returns the replicas.
 Return value: *JSON object*.

For more information see the [MSSQL plugin](#) readme.

mssql.version

 Returns the MSSQL version.
 Return value: *String*.

For more information see the [MSSQL plugin](#) readme.

mysql.custom.query[connString,<user>,<password>,queryName,<args...>]

 Returns the result of a custom query.
 Return value: *JSON object*.

Parameters:

- **connString** - URI or session name;

- **user, password** - MySQL login credentials;

- **queryName** - name of a custom query, must match SQL file name without an extension;

- **args** - one or several comma-separated arguments to pass to a query.

For more information see the [MySQL plugin](#) readme.

mysql.db.discovery[connString,<user>,<password>]

 Returns the list of MySQL databases. Used for **low-level discovery**.
 Return value: The result of the "show databases" SQL query in LLD JSON format.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials.

mysql.db.size[connString,<user>,<password>,<database name>]

 The database size in bytes.
 Return value: Result of the "select coalesce(sum(data_length + index_length),0) as size from information_schema.tables where table_schema=?" SQL query for specific database in bytes.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials;

- **database name** - the database name.

mysql.get_status_variables[connString,<user>,<password>]

 Values of the global status variables.
 Return value: Result of the "show global status" SQL query in JSON format.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials.

mysql.ping[connString,<user>,<password>]

 Test if a connection is alive or not.
 Return value: *1* - the connection is alive; *0* - the connection is broken (if there is any error presented including AUTH and configuration issues).

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials.

mysql.replication.discovery[connString,<user>,<password>]

 Returns the list of MySQL replications. Used for **low-level discovery**.
 Return value: The result of the "show slave status" SQL query in LLD JSON format.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials.

mysql.replication.get_slave_status[connString,<user>,<password>,<master host>]

 The replication status.
 Return value: Result of the "show slave status" SQL query in JSON format.

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials;

- **master host** - the replication master host name. If none found, an error is returned. If this parameter is not specified, all hosts are returned.

mysql.version[connString,<user>,<password>]

 The MySQL version.
 Return value: *String* (with the MySQL instance version).

Parameters:

- **connString** - the URI or session name;

- **user, password** - the MySQL login credentials.

net.dns.get[<ip>,name,<type>,<timeout>,<count>,<protocol>,"<flags>"]

Performs a DNS query and returns detailed DNS record information.
 This item is an extended version of the `net.dns.record` Zabbix agent item with more record types and customizable flags supported.
 Return values: *JSON object*

Parameters:

- **ip** - the IP address of DNS server (leave empty for the default DNS server);
- **name** - the DNS name to query;
- **type** - the record type to be queried (default is *SOA*);
- **timeout** - the timeout for the request in seconds (default is 1 second);
- **count** - the number of tries for the request (default is 2);
- **protocol** - the protocol used to perform DNS queries: *udp* (default) or *tcp*;
- **flags** - one or more comma-separated arguments to pass to a query.

Comments:

- The possible values for type are: *A, NS, MD, MF, CNAME, SOA, MB, MG, MR, NULL, PTR, HINFO, MINFO, MX, TXT, RP, AFSDB, X25, ISDN, RT, NSAPPTR, SIG, KEY, PX, GPOS, AAAA, LOC, NXT, EID, NIMLOC, SRV, ATMA, NAPTR, KX, CERT, DNAME, OPT, APL, DS, SSHFP, IPSECKEY, RRSIG, NSEC, DNSKEY, DHCID, NSEC3, NSEC3PARAM, TLSA, SMIMEA, HIP, NINFO, RKEY, TALINK, CDS, CDNSKEY, OPENPGPKEY, CSYNC, ZONEMD, SVCB, HTTPS, SPF, UINFO, UID, GID, UNSPEC, NID, L32, L64, LP, EUI48, EUI64, URI, CAA, AVC, AMTRELAY*. Note that values must be in uppercase only; lowercase or mixed case values are not supported.
- For reverse DNS lookups (when type is set to *PTR*), you can provide the DNS name in both reversed and non-reversed format (see examples below). Note that when *PTR* record is requested, the DNS name is actually an IP address.
- The possible values for flags are: *cdflag* or *nocdflag* (default), *rdflag* (default) or *nordflag*, *dnssec* or *nodnssec* (default), *nsid* or *nonsid* (default), *edns0* (default) or *noedns0*, *aaflag* or *noaaflag* (default), *adflag* or *noadflag* (default). The flags *dnssec* and *nsid* cannot be used together with *noedns0*, as both require *edns0*. Note that values must be in lowercase only; uppercase case or mixed case values are not supported.
- Internationalized domain names are not supported, please use IDNA encoded names instead.
- The output is an object containing DNS record information based on the parameters provided (see [more details](#)).

Examples:

```
net.dns.get[192.0.2.0,example.com,DNSKEY,3,3,tcp,"cdflag,rdflag,nsid"]
```

```
net.dns.get[,198.51.100.1,PTR,,,,,"cdflag,rdflag,nsid"]
```

```
net.dns.get[,1.100.51.198.in-addr.arpa,PTR,,,,,"cdflag,rdflag,nsid"]
```

```
net.dns.get[,2a00:1450:400f:800::200e,PTR,,,,,"cdflag,rdflag,nsid"]
```

```
net.dns.get[,e.0.0.2.0.0.0.0.0.0.0.0.0.0.0.0.0.8.0.f.0.0.4.0.5.4.1.0.0.a.2.ip6.arpa,PTR,,,,,"cdflag,rdflag,nsid"]
```

```
nvml.device.count
```

 The number of GPU devices.
 Return value: *Integer*.

For more information see the [NVIDIA GPU plugin](#) readme.

```
nvml.device.decoder.utilization[<deviceUUID>]
```

 GPU device decoder utilization as a percentage.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.ecc.mode[<deviceUUID>]`

 GPU device ECC mode information (current, pending).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.encoder.stats.get[<deviceUUID>]`

 GPU device encoder statistics.
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.encoder.utilization[<deviceUUID>]`

 GPU device encoder utilization as a percentage.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.energy.consumption[<deviceUUID>]`

 GPU device total energy consumption in millijoules (mj) since the driver was last reloaded.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.errors.memory[<deviceUUID>]`

 GPU device ECC memory error information (corrected, uncorrected).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.errors.register[<deviceUUID>]`

 GPU device ECC register error information (corrected, uncorrected).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.fan.speed.avg[<deviceUUID>]`

 GPU device average fan speed as a percentage of maximum speed.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.get`

 Discovered GPUs with UUID and name.
 Return value: *JSON*.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.graphics.frequency[<deviceUUID>]`

 GPU device graphics clock speed in MHz.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.memory.fb.get[<deviceUUID>]`

 GPU device framebuffer memory statistics (total, reserved, free, used).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.memory.bar1.get[<deviceUUID>]`

 GPU device BAR1 memory statistics (total, free, used).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.memory.frequency[<deviceUUID>]`

 GPU device memory clock speed in MHz.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.pci.utilization[<deviceUUID>]`

 GPU device PCI utilization (transmit/receive throughput in KBps).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.performance.state[<deviceUUID>]`

 GPU device performance state.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.power.limit[<deviceUUID>]`

 GPU device power limit in milliwatts.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.power.usage[<deviceUUID>]`

 GPU device current power usage in milliwatts.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.serial[<deviceUUID>]`

 GPU device serial number.
 Return value: *String*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.sm.frequency[<deviceUUID>]`

 GPU device streaming multiprocessor clock speed in MHz.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.temperature[<deviceUUID>]`

 GPU device temperature in Celsius.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.utilization[<deviceUUID>]`

 GPU device utilization statistics (GPU/memory utilization as a percentage).
 Return value: *JSON*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.device.video.frequency[<deviceUUID>]`

 GPU device video clock speed in MHz.
 Return value: *Integer*.

Parameter:

- **deviceUUID** - GPU device UUID.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.system.driver.version`

 The NVIDIA driver version.
 Return value: *String*.

For more information see the [NVIDIA GPU plugin](#) readme.

`nvml.version`

 The NVML library version.
 Return value: *String*.

For more information see the [NVIDIA GPU plugin](#) readme.

`oracle.diskgroups.stats[connString,<user>,<password>,<service>,<diskgroup>]`

 Returns the Automatic Storage Management (ASM) disk groups statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **diskgroup** - the name of the ASM disk group to query.

`oracle.diskgroups.discovery[connString,<user>,<password>,<service>]`

 Returns the list of ASM disk groups. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.archive.info[connString,<user>,<password>,<service>,<destination>]

 The archive logs statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **destination** - the name of the destination to query.

oracle.cdb.info[connString,<user>,<password>,<service>,<database>]

 The Container Databases (CDBs) information.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **destination** - the name of the database to query.

oracle.custom.query[connString,<user>,<password>,<service>,queryName,<args...>]

 The result of a custom query.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **queryName** - the name of a custom query, must match SQL file name without an extension;

- **args** - one or several comma-separated arguments to pass to the query.

Comments: - Returned data is automatically converted into JSON. - Avoid returning JSON directly from queries, as it will become corrupted when the plugin attempts to convert it into JSON again.

oracle.datafiles.stats[connString,<user>,<password>,<service>]

 Returns the data files statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **diskgroup** - the name of the ASM disk group to query.

oracle.db.discovery[connString,<user>,<password>,<service>]

 Returns the list of databases. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.fra.stats[connString,<user>,<password>,<service>]

 Returns the Fast Recovery Area (FRA) statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.instance.info[connString,<user>,<password>,<service>]

 The instance statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.pdb.info[connString,<user>,<password>,<service>,<database>]

 The Pluggable Databases (PDBs) information.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **destination** - the name of the database to query.

oracle.pdb.discovery[connString,<user>,<password>,<service>]

 Returns the list of PDBs. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.pga.stats[connString,<user>,<password>,<service>]

 Returns the Program Global Area (PGA) statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.ping[connString,<user>,<password>,<service>]

 Test whether a connection to Oracle can be established.
 Return value: *1* - the connection is successful; *0* - the connection is broken (if there is any error presented including AUTH and configuration issues).

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.proc.stats[connString,<user>,<password>,<service>]

 Returns the processes statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.redolog.info[connString,<user>,<password>,<service>]

 The log file information from the control file.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.sga.stats[connString,<user>,<password>,<service>]

 Returns the System Global Area (SGA) statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.sessions.stats[connString,<user>,<password>,<service>,<lockMaxTime>]

 Returns the sessions statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **lockMaxTime** - the maximum session lock duration in seconds to count the session as a prolongedly locked. Default: 600 seconds.

oracle.sys.metrics[connString,<user>,<password>,<service>,<duration>]

 Returns a set of system metric values.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **duration** - the capturing interval (in seconds) of system metric values. Possible values: 60 — long duration (default), 15 — short duration.

oracle.sys.params[connString,<user>,<password>,<service>]

 Returns a set of system parameter values.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as `sysdba`, as `sysoper`, or as `sysasm` in the format `user as sysdba` (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.ts.stats[connString,<user>,<password>,<service>,<tablespace>,<type>,<conname>]

 Returns the tablespaces statistics.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **tablespace** - name of the tablespace to query. Default (if left empty and type is set):
- "TEMP" (if type is set to "TEMPORARY");
- "USERS" (if type is set to "PERMANENT").
- **type** - the type of the tablespace to query. Default (if tablespace is set): "PERMANENT".
- **conname** - name of the container for which the information is required.

If tablespace, type, or conname is omitted, the item will return tablespace statistics for all matching containers (including PDBs and CDB).

oracle.ts.discovery[connString,<user>,<password>,<service>]

 Returns a list of tablespaces. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

oracle.user.info[connString,<user>,<password>,<service>,<username>]

 Returns Oracle user information.
 Return value: *JSON object*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name;

- **username** - the username for which the information is needed. Lowercase usernames are not supported. Default: current user.

oracle.version[connString,<user>,<password>,<service>]

 Returns the database server version.
 Return value: *String*.

Parameters:

- **connString** - the URI or session name;

- **user** - the Oracle username, supports appending one of the login options as sysdba, as sysoper, or as sysasm in the format user as sysdba (a login option is case-insensitive, must not contain a trailing space);

- **password** - the Oracle password;

- **service** - the Oracle service name.

pgsql.autovacuum.count[uri,<username>,<password>,<database name>]

 The number of autovacuum workers.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.archive[uri,<username>,<password>,<database name>]

 The information about archived files.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.bgwriter[uri,<username>,<password>,<database name>]

 The combined number of checkpoints for the database cluster, broken down by checkpoint type.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.cache.hit[uri,<username>,<password>,<database name>]

 The PostgreSQL buffer cache hit rate.
 Return value: *Float*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.connections[uri,<username>,<password>,<database name>]

 Returns connections by type.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.custom.query[uri,<username>,<password>,queryName,<args...>]

 Returns the result of a custom query.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **queryName** - the name of a custom query, must match the SQL file name without an extension;

- **args** - one or several comma-separated arguments to pass to a query.

pgsql.db.age[uri,<username>,<password>,<database name>]

 The age of the oldest FrozenXID of the database.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.db.bloating_tables[uri,<username>,<password>,<database name>]

 The number of bloating tables per database.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.db.discovery[uri,<username>,<password>,<database name>]

 The list of PostgreSQL databases. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.db.size[uri,<username>,<password>,<database name>]

 The database size in bytes.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.dbstat[uri,<username>,<password>,<database name>]

 Collects the statistics per database. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.dbstat.sum[uri,<username>,<password>,<database name>]

 The summarized data for all databases in a cluster.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.locks[uri,<username>,<password>,<database name>]

 The information about granted locks per database. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.oldest.xid[uri,<username>,<password>,<database name>]

 The age of the oldest XID.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.ping[uri,<username>,<password>,<database name>]

 Tests whether a connection is alive or not.
 Return value: *1* - the connection is alive; *0* - the connection is broken (if there is any error presented including AUTH and configuration issues).

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.queries[uri,<username>,<password>,<database name>,<time period>]

 Queries metrics by execution time.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name;

- **timePeriod** - the execution time limit for the count of slow queries (must be a positive integer).

pgsql.replication.count[uri,<username>,<password>]

 The number of standby servers.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.replication.process[uri,<username>,<password>]

 The flush lag, write lag and replay lag per each sender process.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.replication.process.discovery[uri,<username>,<password>]

 The replication process name discovery.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.replication.recovery_role[uri,<username>,<password>]

 The recovery status.
 Return value: *0* - master mode; *1* - recovery is still in progress (standby mode).

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.replication.status[uri,<username>,<password>]

 The status of replication.
 Return value: *0* - streaming is down; *1* - streaming is up; *2* - master mode.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.replication_lag.b[uri,<username>,<password>]

 The replication lag in bytes.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.replication_lag.sec[uri,<username>,<password>]

 The replication lag in seconds.
 Return value: *Integer*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials.

pgsql.uptime[uri,<username>,<password>,<database name>]

 The PostgreSQL uptime in milliseconds.
 Return value: *Float*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.version[uri,<username>,<password>,<database name>]

 Returns PostgreSQL version.
 Return value: *String*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

pgsql.wal.stat[uri,<username>,<password>,<database name>]

 The WAL statistics.
 Return value: *JSON object*.

Parameters:

- **uri** - the URI or session name;

- **username, password** - the PostgreSQL credentials;

- **database name** - the database name.

redis.config[connString,<password>,<pattern>]

 Gets the configuration parameters of a Redis instance that match the pattern.
 Return value: *JSON* - if a glob-style pattern was used; single value - if a pattern did not contain any wildcard character.

Parameters:

- **connString** - the URI or session name;

- **password** - the Redis password;

- **pattern** - a glob-style pattern (* by default).

redis.info[connString,<password>,<section>]

 Gets the output of the INFO command.
 Return value: *JSON* - the output is serialized as JSON.

Parameters:

- **connString** - the URI or session name;

- **password** - the Redis password;

- **section** - the [section](#) of information (*default* by default).

redis.ping[connString,<password>]

 Test if a connection is alive or not.
 Return value: *1* - the connection is alive; *0* - the connection is broken (if there is any error presented including AUTH and configuration issues).

Parameters:

- **connString** - the URI or session name;

- **password** - the Redis password.

redis.slowlog.count[connString,<password>]

 The number of slow log entries since Redis was started.
 Return value: *Integer*.

Parameters:

- **connString** - the URI or session name;

- **password** - the Redis password.

smart.attribute.discovery

 Returns a list of S.M.A.R.T. device attributes.
 Return value: *JSON object*.

Comments:

- The following macros and their values are returned: {#NAME}, {#DISKTYPE}, {#ID}, {#ATTRNAME}, {#THRESH};
- HDD, SSD and NVME drive types are supported. Drives can be alone or combined in a RAID. {#NAME} will have an add-on in case of RAID, e.g: {"{#NAME}": "/dev/sda cciss,2"}.

smart.disk.discovery

 Returns a list of S.M.A.R.T. devices.
 Return value: *JSON object*.

Comments:

- The following macros and their values are returned: {#NAME}, {#DISKTYPE}, {#MODEL}, {#SN}, {#PATH}, {#ATTRIBUTES}, {#RAIDTYPE};
- HDD, SSD and NVME drive types are supported. If a drive does not belong to a RAID, the {#RAIDTYPE} will be empty. {#NAME} will have an add-on in case of RAID, e.g: {"{#NAME}": "/dev/sda cciss,2"}.

smart.disk.get[<path>,<raid type>]

 Returns all available properties of S.M.A.R.T. devices.
 Return value: *JSON object*.

Parameters:

- **path** - the disk path, the {#PATH} macro may be used as a value;

- **raid_type** - the RAID type, the {#RAID} macro may be used as a value

Comments:

- HDD, SSD and NVME drive types are supported. Drives can be alone or combined in a RAID;

- The data includes smartctl version and call arguments, and additional fields:
disk_name - holds the name with the required add-ons for RAID discovery, e.g: {"disk_name": "/dev/sda cciss,2"}
disk_type - holds the disk type HDD, SSD, or NVME, e.g: {"disk_type": "ssd"};

- If no parameters are specified, the item will return information about all disks.

systemd.unit.get[unit name,<interface>]

 Returns all properties of a systemd unit.
 Return value: *JSON object*.

Parameters:

- **unit name** - the unit name (you may want to use the {#UNIT.NAME} macro in item prototype to discover the name);

- **interface** - the unit interface type, possible values: *Unit* (default), *Service*, *Socket*, *Device*, *Mount*, *Automount*, *Swap*, *Target*, *Path*.

Comments:

- This item is supported on Linux platform only;
- LoadState, ActiveState and UnitFileState for Unit interface are returned as text and integer: "ActiveState":{"state":1,"text":"a

systemd.unit.info[unit name,<property>,<interface>]

 A systemd unit information.
 Return value: *String*.

Parameters:

- **unit name** - the unit name (you may want to use the {#UNIT.NAME} macro in item prototype to discover the name);

- **property** - unit property (e.g. ActiveState (default), LoadState, Description);
- **interface** - the unit interface type (e.g. Unit (default), Socket, Service).

Comments:

- This item is supported on Linux platform only;
- This item allows to retrieve a specific property from specific type of interface as described in [dbus API](#).

Examples:

```
systemd.unit.info["{#UNIT.NAME}"] #collect active state (active, reloading, inactive, failed, activating,
systemd.unit.info["{#UNIT.NAME}",LoadState] #collect load state info on discovered systemd units
systemd.unit.info[mysqld.service,Id] #retrieve the service technical name (mysqld.service)
systemd.unit.info[mysqld.service,Description] #retrieve the service description (MySQL Server)
systemd.unit.info[mysqld.service,ActiveEnterTimestamp] #retrieve the last time the service entered the act
systemd.unit.info[dbus.socket,NConnections,Socket] #collect the number of connections from this socket uni

systemd.unit.discovery[<type>]
```

 List of systemd units and their details. Used for **low-level discovery**.
 Return value: *JSON object*.

Parameter:

- **type** - possible values: *all*, *automount*, *device*, *mount*, *path*, *service* (default), *socket*, *swap*, *target*.

This item is supported on Linux platform only.

web.certificate.get[hostname,<port>,<address>]

 Validates the certificates and returns certificate details.
 Return value: *JSON object*.

Parameters:

- **hostname** - can be either IP or DNS.
May contain the URL scheme (*https* only), path (it will be ignored), and port.
If a port is provided in both the first and the second parameters, their values must match.
If address (the 3rd parameter) is specified, the hostname is only used for SNI and hostname verification;

- **port** - the port number (default is 443 for HTTPS);

- **address** - can be either IP or DNS. If specified, it will be used for connection, and hostname (the 1st parameter) will be used for SNI, and host verification. In case, the 1st parameter is an IP and the 3rd parameter is DNS, the 1st parameter will be used for connection, and the 3rd parameter will be used for SNI and host verification.

Comments:

- This item turns unsupported if the destination specified in the host configuration does not exist, is unavailable, or if the TLS handshake fails with any error except an invalid certificate;

- Currently, AIA (Authority Information Access) X.509 extension, CRLs and OCSP (including OCSP stapling), and Certificate Transparency are not supported;
- JSON response fields:
 - *x509*: contains the details of the X.509 certificate.
 - * *version*: the X.509 version (e.g., 3).
 - * *serial_number*: the serial number of the certificate.
 - * *signature_algorithm*: the algorithm used to sign the certificate (e.g., SHA256-RSA).
 - * *issuer*: the issuer of the certificate.

- * *not_before*: the start date of the certificate's validity.
- * *not_after*: the expiration date of the certificate.
- * *subject*: the subject of the certificate.
- * *public_key_algorithm*: the algorithm used for the public key (e.g., RSA).
- * *alternative_names*: subject alternative names (if present), otherwise null.
- *result*: contains the validation result.
 - * *value*: the validation status (see possible values below).
 - * *message*: detailed validation message (e.g., "certificate verified successfully").
- *sha1_fingerprint*: the SHA-1 fingerprint of the certificate.
- *sha256_fingerprint*: the SHA-256 fingerprint of the certificate.
- The \$.result.value field indicates the certificate validation result. Possible values include:
 - *valid* - the certificate is valid and trusted.
 - *valid-but-self-signed* - the certificate is valid but self-signed, meaning its subject matches its issuer.
 - *invalid* - the certificate is invalid due to an issue such as expiration, incorrect hostname, or an unknown signing authority.

Example:

```
web.certificate.get[example.com,443]
```

JSON Response:

```
{

}
```

2 Windows Zabbix agent

Overview

The Windows Zabbix agent items are presented in two lists:

- **Shared items** - the item keys that are shared with the UNIX Zabbix agent;
- **Windows-specific items** - the item keys that are supported **only** on Windows.

Note that all item keys supported by Zabbix agent on Windows are also supported by the new generation Zabbix agent 2. See the **additional item keys** that you can use with the agent 2 only.

See also: **Minimum permissions for Windows items**

Shared items

The table below lists Zabbix agent items that are supported on Windows and are shared with the UNIX Zabbix agent:

- The item key is a link to full details of the UNIX Zabbix agent item
- Windows-relevant item comments are included

| Item key | Description | Item group |
|--------------------------------------|--|----------------|
| log | The monitoring of a log file. This item is not supported for Windows Event Log. | Log monitoring |
| log.count | The <code>persistent_dir</code> parameter is not supported on Windows. The count of matched lines in a monitored log file. This item is not supported for Windows Event Log. | |
| logrt | The <code>persistent_dir</code> parameter is not supported on Windows. The monitoring of a log file that is rotated. This item is not supported for Windows Event Log. | |
| logrt.count | The <code>persistent_dir</code> parameter is not supported on Windows. The count of matched lines in a monitored log file that is rotated. This item is not supported for Windows Event Log. | |
| modbus.get | The <code>persistent_dir</code> parameter is not supported on Windows. Reads Modbus data. | Modbus Network |
| net.dns | Checks if the DNS service is up. The <code>ip</code> , <code>timeout</code> and <code>count</code> parameters are ignored on Windows unless using Zabbix agent 2. | |
| net.dns.perf | Checks the performance of a DNS service. The <code>ip</code> , <code>timeout</code> and <code>count</code> parameters are ignored on Windows unless using Zabbix agent 2. | |
| net.dns.record | Performs a DNS query. The <code>ip</code> , <code>timeout</code> and <code>count</code> parameters are ignored on Windows unless using Zabbix agent 2. | |
| net.if.discovery | The list of network interfaces. Some Windows versions (for example, Server 2008) might require the latest updates installed to support non-ASCII characters in interface names. | |
| net.if.in | The incoming traffic statistics on a network interface. On Windows, the item gets values from 64-bit counters if available. 64-bit interface statistic counters were introduced in Windows Vista and Windows Server 2008. If 64-bit counters are not available, the agent uses 32-bit counters. Multi-byte interface names on Windows are supported. You may obtain network interface descriptions on Windows with <code>net.if.discovery</code> or <code>net.if.list</code> items. | |
| net.if.out | The outgoing traffic statistics on a network interface. On Windows, the item gets values from 64-bit counters if available. 64-bit interface statistic counters were introduced in Windows Vista and Windows Server 2008. If 64-bit counters are not available, the agent uses 32-bit counters. Multi-byte interface names on Windows are supported. You may obtain network interface descriptions on Windows with <code>net.if.discovery</code> or <code>net.if.list</code> items. | |
| net.if.total | The sum of incoming and outgoing traffic statistics on a network interface. On Windows, the item gets values from 64-bit counters if available. 64-bit interface statistic counters were introduced in Windows Vista and Windows Server 2008. If 64-bit counters are not available, the agent uses 32-bit counters. You may obtain network interface descriptions on Windows with <code>net.if.discovery</code> or <code>net.if.list</code> items. | |
| net.tcp.listen | Checks if this TCP port is in LISTEN state. | |
| net.tcp.port | Checks if it is possible to make a TCP connection to the specified port. | |
| net.tcp.service | Checks if a service is running and accepting TCP connections. Checking of LDAP and HTTPS on Windows is only supported by Zabbix agent 2. | |
| net.tcp.service.perf | Checks the performance of a TCP service. Checking of LDAP and HTTPS on Windows is only supported by Zabbix agent 2. | |
| net.tcp.socket.count | Returns the number of TCP sockets that match parameters. This item is supported on Linux by Zabbix agent, but on Windows it is supported only by Zabbix agent 2 on 64-bit Windows. | |
| net.udp.service | Checks if a service is running and responding to UDP requests. | |
| net.udp.service.perf | Checks the performance of a UDP service. | |

| Item key | Description | Item group |
|-----------------------------------|---|----------------------|
| <code>net.udp.socket.count</code> | Returns the number of UDP sockets that match parameters. This item is supported on Linux by Zabbix agent, but on Windows it is supported only by Zabbix agent 2 on 64-bit Windows. | |
| <code>proc.num</code> | The number of processes. On Windows, only the <code>name</code> and <code>user</code> parameters are supported. | Processes |
| <code>system.cpu.discovery</code> | The list of detected CPUs/CPU cores. | System |
| <code>system.cpu.load</code> | The CPU load. When a collector process is started on Zabbix agent, the following performance counters are initialized and later used for this item: <code>\System\Processor Queue Length</code> | |
| <code>system.cpu.num</code> | The number of CPUs. | |
| <code>system.cpu.util</code> | The CPU utilization percentage. The value is acquired using the <i>Processor Time</i> performance counter. Note that since Windows 8 its Task Manager shows CPU utilization based on the <i>Processor Utility</i> performance counter, while in previous versions it was the <i>Processor Time</i> counter (see more details). <i>system</i> is the only type parameter supported on Windows. | |
| <code>system.hostname</code> | The system host name. The value is acquired by either <code>GetComputerName()</code> (for netbios), <code>GetComputerNameExA()</code> (for fqdn), or <code>gethostname()</code> (for host) functions on Windows. See also a more detailed description . | |
| <code>system.localtime</code> | The system time. | |
| <code>system.run</code> | Run the specified command on the host. | |
| <code>system.sw.arch</code> | The software architecture information. | |
| <code>system.swap.size</code> | The swap space size in bytes or in percentage from total. The <code>used</code> type parameter is supported on Linux by Zabbix agent, but on Windows it is supported only by Zabbix agent 2 . Note that this key might report incorrect swap space size/percentage on virtualized (VMware ESXi, VirtualBox) Windows platforms. In this case you may use the <code>perf_counter[\700(_Total)\702]</code> key to obtain correct swap space percentage. | |
| <code>system.uname</code> | Identification of the system. On Windows the value for this item is obtained from <code>Win32_OperatingSystem</code> and <code>Win32_Processor</code> WMI classes. The OS name (including edition) might be translated to the user's display language. On some versions of Windows it contains trademark symbols and extra spaces. | |
| <code>system.uptime</code> | The system uptime in seconds. | |
| <code>vfs.dir.count</code> | The directory entry count. On Windows, directory symlinks are skipped and hard links are counted only once. | Virtual file systems |
| <code>vfs.dir.get</code> | The directory entry list. On Windows, directory symlinks are skipped and hard links are counted only once. | |
| <code>vfs.dir.size</code> | The directory size. On Windows any symlink is skipped and hard links are taken into account only once. | |
| <code>vfs.file.cksum</code> | The file checksum, calculated by the UNIX cksum algorithm. | |
| <code>vfs.file.contents</code> | Retrieving the contents of a file. | |
| <code>vfs.file.exists</code> | Checks if the file exists. On Windows the double quotes have to be backslash <code>'\'</code> escaped and the whole item key enclosed in double quotes when using the command line utility for calling <code>zabbix_get.exe</code> or <code>agent2</code> . Note that the item may turn unsupported on Windows if a directory is searched within a non-existing directory, e.g. <code>vfs.file.exists[C:\no\dir,dir]</code> (where <code>'no'</code> does not exist). | |
| <code>vfs.file.get</code> | Returns information about a file. Supported file types on Windows: regular file, directory, symbolic link | |
| <code>vfs.file.md5sum</code> | The MD5 checksum of file. | |
| <code>vfs.file.owner</code> | Retrieves the owner of a file. | |
| <code>vfs.file.regexp</code> | Retrieve a string in the file. | |
| <code>vfs.file.regmatch</code> | Find a string in the file. | |
| <code>vfs.file.size</code> | The file size. | |

| Item key | Description | Item group |
|------------------------------------|--|----------------|
| vfs.file.time | The file time information. On Windows XP <code>vfs.file.time[file,change]</code> may be equal to <code>vfs.file.time[file,access]</code> . | |
| vfs.fs.discovery | The list of mounted filesystems with their type and mount options. The <code>{#FSLABEL}</code> macro is supported on Windows. | |
| vfs.fs.get | The list of mounted filesystems with their type, available disk space, inode statistics and mount options. The <code>{#FSLABEL}</code> macro is supported on Windows. | |
| vfs.fs.size | The disk space in bytes or in percentage from total. | |
| vm.memory.size | The memory size in bytes or in percentage from total. | Virtual memory |
| web.page.get | Get the content of a web page. | Web monitoring |
| web.page.perf | The loading time of a full web page. | |
| web.page.regex | Find a string on the web page. | |
| agent.hostmetadata | The agent host metadata. | Zabbix |
| agent.hostname | The agent host name. | |
| agent.ping | The agent availability check. | |
| agent.variant | The variant of Zabbix agent (Zabbix agent or Zabbix agent 2). | |
| agent.version | The version of Zabbix agent. | |
| zabbix.stats | Returns a set of Zabbix server or proxy internal metrics remotely. | |
| zabbix.stats | Returns the number of monitored items in the queue which are delayed on Zabbix server or proxy remotely. | |

Windows-specific items

The table provides details on the item keys that are supported **only** by the Windows Zabbix agent.

Windows-specific items sometimes are an approximate counterpart of a similar agent item, for example `proc_info`, supported on Windows, roughly corresponds to the `proc.mem` item, not supported on Windows.

The item key is a link to full item key details.

| Item key | Description | Item group |
|--|---|----------------------|
| eventlog | The Windows event log monitoring. | Log monitoring |
| eventlog.count | The count of lines in the Windows event log. | |
| net.if.list | The network interface list (includes interface type, status, IPv4 address, description). | Network |
| perf_counter | The value of any Windows performance counter. | Performance counters |
| perf_counter_en | The value of any Windows performance counter in English. | |
| perf_instance.discovery | The list of object instances of Windows performance counters. | |
| perf_instance_en.discovery | The list of object instances of Windows performance counters, discovered using the object names in English. | |
| proc_info | Various information about specific process(es). | Processes |
| registry.data | Return data for the specified value name in the Windows Registry key. | Registry |
| registry.get | The list of Windows Registry values or keys located at given key. | |
| service.discovery | The list of Windows services. | Services |
| service.info | Information about a service. | |
| services | The listing of services. | |
| vm.vmemory.size | The virtual memory size in bytes or in percentage from the total. | Virtual memory |
| wmi.get | Execute a WMI query and return the first selected object. | WMI |
| wmi.getall | Execute a WMI query and return the whole response. | |

Item key details

Parameters without angle brackets are mandatory. Parameters marked with angle brackets `< >` are optional.

`eventlog[name,<regex>,<severity>,<source>,<eventid>,<maxlines>,<mode>]`

 The event log monitoring.
 Return value: *Log*.

Parameters:

- **name** - the name of the event log channel (*Log Name* in the Event Viewer GUI);

- **regexp** - a regular **expression** describing the required pattern (case sensitive);

- **severity** - a regular expression describing severity (case insensitive). This parameter accepts a regular expression based on the following values: "Information", "Warning", "Error", "Critical", "Verbose" (running on Windows Vista or newer).

- **source** - a regular expression describing the source identifier (case insensitive);

- **eventid** - a regular expression describing the event identifier(s) (case sensitive);

- **maxlines** - the maximum number of new lines per second the agent will send to Zabbix server or proxy. This parameter overrides the value of 'MaxLinesPerSecond' in `zabbix_agentd.conf`.

- **mode** - possible values: *all* (default) or *skip* - skip the processing of older data (affects only newly created items).

Comments:

- The item must be configured as an **active check**;
- The agent is unable to send in events from the "Forwarded events" log;
- Windows Eventing 6.0 is supported;
- Selecting a non-Log **type of information** for this item will lead to the loss of local timestamp, as well as log severity and source information;
- See also additional information on **log monitoring**.

Examples:

```
eventlog[Application]
eventlog[Microsoft-Windows-Application-Experience/Program-Compatibility-Assistant]
eventlog[Security,, "Failure Audit",, ~(529|680)$]
eventlog[System,, "Warning|Error"]
eventlog[System,,, ^1$]
eventlog[Windows PowerShell,,,,, skip]
eventlog[System,,, @TWOSHORT] #here a custom regular expression named `TWOSHORT` is referenced (defined as
eventlog.count[name,<regexp>,<severity>,<source>,<eventid>,<maxproclines>,<mode>]
```

 The count of lines in the Windows event log.
 Return value: *Integer*.

Parameters:

- **name** - the name of the event log channel (*Log Name* in the Event Viewer GUI);

- **regexp** - a regular **expression** describing the required pattern (case sensitive);

- **severity** - a regular expression describing severity (case insensitive). This parameter accepts a regular expression based on the following values: "Information", "Warning", "Error", "Critical", "Verbose" (running on Windows Vista or newer).

- **source** - a regular expression describing the source identifier (case insensitive);

- **eventid** - a regular expression describing the event identifier(s) (case sensitive);

- **maxproclines** - the maximum number of new lines per second the agent will analyze (cannot exceed 10000). The default value is 10*'MaxLinesPerSecond' in `zabbix_agentd.conf`.

- **mode** - possible values: *all* (default) or *skip* - skip the processing of older data (affects only newly created items).

Comments:

- The item must be configured as an **active check**;
- The agent is unable to send in events from the "Forwarded events" log;
- Windows Eventing 6.0 is supported;
- Selecting a non-Log **type of information** for this item will lead to the loss of local timestamp, as well as log severity and source information;
- See also additional information on **log monitoring**.

Examples:

```
eventlog.count[System, "Warning|Error"]
eventlog.count[Windows PowerShell,,,,, skip]
net.if.list
```

 The network interface list (includes interface type, status, IPv4 address, description).
 Return value: *Text*.

Comments:

- Multi-byte interface names supported;
- Disabled interfaces are not listed;
- Enabling/disabling some components may change their ordering in the Windows interface name;

- Some Windows versions (for example, Server 2008) might require the latest updates installed to support non-ASCII characters in interface names.

`perf_counter[counter,<interval>]`

 The value of any Windows performance counter.
 Return value: *Integer, float, string* or *text* (depending on the request).

Parameters:

- **counter** - the path to the counter;

- **interval** - the last N seconds for storing the average value. The `interval` must be between 1 and 900 seconds (included) and the default value is 1.

Comments:

- `interval` is used for counters that require more than one sample (like CPU utilization), so the check returns an average value for last "interval" seconds every time;
- Performance Monitor can be used to obtain the list of available counters.
- See also: [Windows performance counters](#).

`perf_counter_en[counter,<interval>]`

 The value of any Windows performance counter in English.
 Return value: *Integer, float, string* or *text* (depending on the request).

Parameters:

- **counter** - the path to the counter in English;

- **interval** - the last N seconds for storing the average value. The `interval` must be between 1 and 900 seconds (included) and the default value is 1.

Comments:

- `interval` is used for counters that require more than one sample (like CPU utilization), so the check returns an average value for last "interval" seconds every time;
- This item is only supported on **Windows Server 2008/Vista** and above;
- You can find the list of English strings by viewing the following registry key: `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib\009`.

`perf_instance.discovery[object]`

 The list of object instances of Windows performance counters. Used for [low-level discovery](#).
 Return value: *JSON object*.

Parameter:

- **object** - the object name (localized).

`perf_instance_en.discovery[object]`

 The list of object instances of Windows performance counters, discovered using the object names in English. Used for [low-level discovery](#).
 Return value: *JSON object*.

Parameter:

- **object** - the object name (in English).

`proc_info[process,<attribute>,<type>]`

 Various information about specific process(es).
 Return value: *Float*.

Parameters:

- **process** - the process name;

- **attribute** - the requested process attribute;

- **type** - the representation type (meaningful when more than one process with the same name exists)

Comments:

- The following `attributes` are supported:
`vmsize` (default) - size of process virtual memory in Kbytes
`wkset` - size of process working set (amount of physical memory used by process) in Kbytes
`pf` - number of page faults
`ktime` - process kernel time in milliseconds
`utime` - process user time in milliseconds
`io_read_b` - number of bytes read by process during I/O operations
`io_read_op` - number of read operation performed by process
`io_write_b` - number of bytes written by process during I/O operations
`io_write_op` - number of write operation performed by process
`io_other_b` - number of bytes transferred by process during operations other than read and write operations
`io_other_op` - number of I/O operations performed by process, other than read and write operations
`gdiobj` - number of GDI objects used by process
`userobj` - number of USER objects used by process;

- Valid types are:
avg (default) - average value for all processes named <process>
min - minimum value among all processes named <process>
max - maximum value among all processes named <process>
sum - sum of values for all processes named <process>;
- On a 64-bit system, a 64-bit Zabbix agent is required for this item to work correctly.

Examples:

```
proc_info[iexplore.exe,wkset,sum] #retrieve the amount of physical memory taken by all Internet Explorer p
proc_info[iexplore.exe,pf,avg] #retrieve the average number of page faults for Internet Explorer processes
```

```
registry.data[key,<value name>]
```

 Return data for the specified value name in the Windows Registry key.
 Return value: *Integer*, *string* or *text* (depending on the value type)

Parameters:

- **key** - the registry key including the root key; root abbreviations (e.g. HKLM) are allowed;
- **value name** - the registry value name in the key (empty string "" by default). The default value is returned if the value name is not supplied.

Comments:

- Supported root abbreviations:
HKCR - HKEY_CLASSES_ROOT
HKCC - HKEY_CURRENT_CONFIG
HKCU - HKEY_CURRENT_USER
HKCULS - HKEY_CURRENT_USER_LOCAL_SETTINGS
HKLM - HKEY_LOCAL_MACHINE
HKPD - HKEY_PERFORMANCE_DATA
HKPN - HKEY_PERFORMANCE_NLSTEXT
HKPT - HKEY_PERFORMANCE_TEXT
HKU - HKEY_USERS

- Keys with spaces must be double-quoted.

Examples:

```
registry.data["HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Windows Error Reporting"] #return the data of
registry.data["HKLM\SOFTWARE\Microsoft\Windows\Windows Error Reporting","EnableZip"] #return the data of t
```

```
registry.get[key,<mode>,<name regexp>]
```

 The list of Windows Registry values or keys located at given key.
 Return value: *JSON object*.

Parameters:

- **key** - the registry key including the root key; root abbreviations (e.g. HKLM) are allowed (see comments for registry.data[]) to see full list of abbreviations);

- **mode** - possible values:
values (default) or *keys*;

- **name regexp** - only discover values with names that match the regexp (default - discover all values). Allowed only with *values* as mode.

Keys with spaces must be double-quoted.

Examples:

```
registry.get[HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall,values,"^DisplayName|DisplayVersion$
registry.get[HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall,values] #return the data of the all
registry.get[HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall,keys] #return all subkeys of this ke
```

```
service.discovery
```

 The list of Windows services. Used for **low-level discovery**.
 Return value: *JSON object*.

```
service.info[service,<param>]
```

 Information about a service.
 Return value: *Integer* - with param as *state*, *startup*; *String* - with param as *displayname*, *path*, *user*; *Text* - with param as *description*
Specifically for *state*: 0 - running, 1 - paused, 2 - start pending, 3 - pause pending, 4 - continue pending, 5 - stop pending, 6 - stopped, 7 - unknown, 255 - no such service
Specifically for *startup*: 0 - automatic, 1 - automatic delayed, 2 - manual, 3 - disabled, 4 - unknown, 5 - automatic trigger start, 6 - automatic delayed trigger start, 7 - manual trigger start

Parameters:

- **service** - a real service name or its display name as seen in the MMC Services snap-in;
- **param** - *state* (default), *displayname*, *path*, *user*, *startup*, or *description*.

Comments:

- Items like `service.info[service,state]` and `service.info[service]` will return the same information;
- Only with param as *state* this item returns a value for non-existing services (255).

Examples:

```
service.info[SNMPTRAP] - state of the SNMPTRAP service;  
service.info[SNMP Trap] - state of the same service, but with the display name specified;  
service.info[EventLog,startup] - the startup type of the EventLog service  
  
services[<type>,<state>,<exclude>]
```

 The listing of services.
 Return value: *0* - if empty; *Text* - the list of services separated by a newline.

Parameters:

- **type** - *all* (default), *automatic*, *manual*, or *disabled*;
- **state** - *all* (default), *stopped*, *started*, *start_pending*, *stop_pending*, *running*, *continue_pending*, *pause_pending*, or *paused*;
- **exclude** - the services to exclude from the result. Excluded services should be listed in double quotes, separated by comma, without spaces.

Examples:

```
services[,started] #returns the list of started services;  
services[automatic, stopped] #returns the list of stopped services that should be running;  
services[automatic, stopped, "service1,service2,service3"] #returns the list of stopped services that should be running;  
  
vm.vmemory.size[<type>]
```

 The virtual memory size in bytes or in percentage from the total.
 Return value: *Integer* - for bytes; *float* - for percentage.

Parameter:

- **type** - possible values: *available* (available virtual memory), *pavailable* (available virtual memory, in percent), *pused* (used virtual memory, in percent), *total* (total virtual memory, default), or *used* (used virtual memory)

Comments:

- The monitoring of virtual memory statistics is based on:

 - Total virtual memory on Windows (total physical + page file size);

 - The maximum amount of memory Zabbix agent can commit;

 - The current committed memory limit for the system or Zabbix agent, whichever is smaller.

Example:

```
vm.vmemory.size[pavailable] #return the available virtual memory, in percentage  
  
wmi.get[<namespace>,<query>]
```

 Execute a WMI query and return the first selected object.
 Return value: *Integer*, *float*, *string* or *text* (depending on the request).

Parameters:

- **namespace** - the WMI namespace;

- **query** - the WMI query returning a single object.

WMI queries are performed with [WQL](#).

Example:

```
wmi.get[root\cimv2,select status from Win32_DiskDrive where Name like '%PHYSICALDRIVE%'] #returns the status of the first disk drive  
  
wmi.getall[<namespace>,<query>]
```

 Execute a WMI query and return the whole response. Can be used for **low-level discovery**.
 Return value: *JSON object*

Parameters:

- **namespace** - the WMI namespace;

- **query** - the WMI query.

Comments:

- WMI queries are performed with [WQL](#).
- JSONPath **preprocessing** can be used to point to more specific values in the returned JSON.

Example:

```
wmi.getall[root\cimv2,select * from Win32_DiskDrive where Name like '%PHYSICALDRIVE%'] #returns status information for all disk drives
```

Monitoring Windows services

This tutorial provides step-by-step instructions for setting up the monitoring of Windows services. It is assumed that Zabbix server and agent are configured and operational.

Step 1

Get the service name.

You can get the service name by going to the MMC Services snap-in and bringing up the properties of the service. In the *General* tab you should see a field called "Service name". The value that follows is the name you will use when setting up an item for monitoring. For example, if you wanted to monitor the "workstation" service, then your service might be: **lanmanworkstation**.

Step 2

Configure an item for monitoring the service.

The item `service.info[service,<param>]` retrieves information about a particular service. Depending on the information you need, specify the `param` option which accepts the following values: *displayname*, *state*, *path*, *user*, *startup* or *description*. The default value is *state* if `param` is not specified (`service.info[service]`).

The type of return value depends on chosen `param`: integer for *state* and *startup*; character string for *displayname*, *path* and *user*; text for *description*.

Example:

- Key: `service.info[lanmanworkstation]`
- Type of information: Numeric (unsigned)

The item `service.info[lanmanworkstation]` will retrieve information about the state of the service as a numerical value. To map a numerical value to a text representation in the frontend ("0" as "Running", "1" as "Paused", etc.), you can configure **value mapping** on the host on which the item is configured. To do this, either **link the template Windows services by Zabbix agent** or **Windows services by Zabbix agent active** to the host, or configure on the host a new value map that is based on the *Windows service state* value map configured on the mentioned templates.

Note that both of the mentioned templates have a discovery rule configured that will discover services automatically. If you do not want this, you can **disable the discovery rule** on the host level once the template has been linked to the host.

Discovery of Windows services

Low-level discovery provides a way to automatically create items, triggers, and graphs for different entities on a computer. Zabbix can automatically start monitoring Windows services on your machine, without the need to know the exact name of a service or create items for each service manually. A filter can be used to generate real items, triggers, and graphs only for services of interest.

2 SNMP agent

Overview

You may want to use SNMP monitoring on devices such as printers, network switches, routers or UPS that usually are SNMP-enabled and on which it would be impractical to attempt setting up complete operating systems and Zabbix agents.

To be able to retrieve data provided by SNMP agents on these devices, Zabbix server must be **initially configured** with SNMP support by specifying the `--with-net-snmp` flag. It is recommended to also **install MIB files** to ensure that item values are displayed in the correct format. Without the MIB files, formatting issues, such as displaying values in HEX instead of UTF-8 or vice versa, may occur.

SNMP checks are performed over the UDP protocol only.

Zabbix server and proxy daemons log lines similar to the following if they receive an incorrect SNMP response:

```
SNMP response from host "gateway" does not contain all of the requested variable bindings
```

While they do not cover all the problematic cases, they are useful for identifying individual SNMP devices for which combined requests should be disabled.

Zabbix server/proxy will always retry at least one time after an unsuccessful query attempt: either through the SNMP library's retrying mechanism or through the internal **combined processing** mechanism.

Warning:

If monitoring SNMPv3 devices, make sure that `msgAuthoritativeEngineID` (also known as `snmpEngineID` or "Engine ID") is never shared by two devices. According to [RFC 2571](#) (section 3.1.1.1) it must be unique for each device.

Warning:

RFC3414 requires the SNMPv3 devices to persist their engineBoots. Some devices do not do that, which results in their SNMP messages being discarded as outdated after being restarted. In such situation, SNMP cache needs to be manually cleared on a server/proxy (by using `-R snmp_cache_reload`) or the server/proxy needs to be restarted.

Configuring SNMP monitoring

To start monitoring a device through SNMP, the following steps have to be performed:

Step 1

Find out the SNMP string (or OID) of the item you want to monitor.

To get a list of SNMP strings, use the **snmpwalk** command (part of [net-snmp](#) software which you should have installed as part of the Zabbix installation) or equivalent tool:

```
snmpwalk -v 2c -c public <host IP> .
```

As '2c' here stands for SNMP version, you may also substitute it with '1', to indicate SNMP Version 1 on the device.

This should give you a list of SNMP strings and their last value. If it doesn't then it is possible that the SNMP 'community' is different from the standard 'public' in which case you will need to find out what it is.

You can then go through the list until you find the string you want to monitor, e.g. if you wanted to monitor the bytes coming in to your switch on port 3 you would use the IF-MIB::ifHCInOctets.3 string from this line:

```
IF-MIB::ifHCInOctets.3 = Counter64: 3409739121
```

You may now use the **snmpget** command to find out the numeric OID for 'IF-MIB::ifHCInOctets.3':

```
snmpget -v 2c -c public -On <host IP> IF-MIB::ifHCInOctets.3
```

Note that the last number in the string is the port number you are looking to monitor. See also: [Dynamic indexes](#).

This should give you something like the following:

```
.1.3.6.1.2.1.31.1.1.1.6.3 = Counter64: 3472126941
```

Again, the last number in the OID is the port number.

Note:

Some of the most used SNMP OIDs are [translated automatically to a numeric representation](#) by Zabbix.

In the last example above value type is "Counter64", which internally corresponds to ASN_COUNTER64 type. The full list of supported types is ASN_COUNTER, ASN_COUNTER64, ASN_INTEGER, ASN_UNSIGNED64, ASN_INTEGER64, ASN_FLOAT, ASN_DOUBLE, ASN_TIMETICKS, ASN_GAUGE, ASN_IPADDRESS, ASN_OCTET_STR and ASN_OBJECT_ID. These types roughly correspond to "Counter32", "Counter64", "UInteger32", "INTEGER", "Float", "Double", "Timeticks", "Gauge32", "IpAddress", "OCTET STRING", "OBJECT IDENTIFIER" in **snmpget** output, but might also be shown as "STRING", "Hex-STRING", "OID" and other, depending on the presence of a display hint.

Step 2

[Create a host](#) corresponding to a device.

Host
Templates
IPMI

* SNMP community

{ \$SNMP_COMMUNITY }

Max repetition count

10

☒ Use combined requests

Add an SNMP interface for the host:

- Enter the IP address/DNS name and port number
- Select the *SNMP version* from the dropdown
- Add interface credentials depending on the selected SNMP version:
 - SNMPv1, v2 require only the community (usually 'public')
 - SNMPv3 requires more specific options (see below)
- Specify the max repetition value (default: 10) for **native SNMP bulk requests** (GetBulkRequest-PDUs); only for discovery [] and walk [] items in SNMPv2 and v3. Note that setting this value too high may cause the SNMP agent check timeout.
- Mark the *Use combined requests* checkbox to allow **combined processing** of SNMP requests (not related to native SNMP bulk requests "walk" and "get")

| SNMPv3 parameter | Description |
|----------------------------------|--|
| <i>Context name</i> | Enter context name to identify item on SNMP subnet. User macros are resolved in this field. |
| <i>Security name</i> | Enter security name. User macros are resolved in this field. |
| <i>Security level</i> | Select security level: noAuthNoPriv - no authentication nor privacy protocols are used AuthNoPriv - authentication protocol is used, privacy protocol is not AuthPriv - both authentication and privacy protocols are used |
| <i>Authentication protocol</i> | Select authentication protocol - <i>MD5</i> , <i>SHA1</i> ; with net-snmp 5.8 and newer <i>SHA224</i> , <i>SHA256</i> , <i>SHA384</i> or <i>SHA512</i> . |
| <i>Authentication passphrase</i> | Enter authentication passphrase. User macros are resolved in this field. |
| <i>Privacy protocol</i> | Select privacy protocol - <i>DES</i> , <i>AES128</i> , <i>AES192</i> , <i>AES256</i> , <i>AES192C</i> (Cisco) or <i>AES256C</i> (Cisco). See notes about privacy protocol support |
| <i>Privacy passphrase</i> | Enter privacy passphrase. User macros are resolved in this field. |

In case of wrong SNMPv3 credentials (security name, authentication protocol/passphrase, privacy protocol):

- Zabbix receives an ERROR from net-snmp, except for wrong *Privacy passphrase* in which case Zabbix receives a TIMEOUT error from net-snmp;
- SNMP interface availability will switch to red (unavailable).

Warning:

Changes in *Authentication protocol*, *Authentication passphrase*, *Privacy protocol* or *Privacy passphrase*, made without changing the *Security name*, will take effect only after the cache on a server/proxy is manually cleared (by using **-R snmp_cache_reload**) or the server/proxy is restarted. In cases, where *Security name* is also changed, all parameters will be updated immediately.

You can use one of the provided SNMP templates that will automatically add a set of items. Before using a template, verify that it is compatible with the host.

Click on *Add* to save the host.

Privacy protocol support

Depending on your operating system and net-snmp configuration, some privacy protocols may not be available:

- On some newer operating systems (for example, RHEL9) support of DES is dropped for the net-snmp package.
- Encryption protocols AES192 and stronger are not supported out-of-the-box on the operating systems older than RHEL 8, CentOS 8, Oracle Linux 8, Debian 12, Ubuntu LTS 22.04, openSUSE Leap 15.5.

To check whether net-snmp library supports AES192+, use one of the following options:

1. `net-snmp-config`:

```
net-snmp-config --configure-options
```

If the output contains `--enable-blumenthal-aes`, AES192+ is supported.

Note that net-snmp-config is part of the development package for SNMP (libsnp-dev for Debian/Ubuntu, net-snmp-devel for CentOS/RHEL/OL/SUSE) and may not be installed by default.

2. `snmpget`:

```
snmpget -v 3 -x AES-256
```

If the output contains `Invalid privacy protocol specified after -3x flag: AES-256`, AES192+ is not supported. If the output contains `No hostname specified.`, AES192+ is not supported.

If your net-snmp library does not support AES192 and higher protocols, recompile net-snmp with `--enable-blumenthal-aes` option, then recompile Zabbix server specifying the option `--with-net-snmp=/home/user/yourcustomnetsnmp/bin/net-snmp-config`

Step 3

Create an item for monitoring.

So, now go back to Zabbix and click on *Items* for the SNMP host you created earlier. Depending on whether you used a template or not when creating your host, you will have either a list of SNMP items associated with your host or just an empty list. We will work on the assumption that you are going to create the item yourself using the information you have just gathered using `snmpwalk` and `snmpget`, so click on *Create item*.

Fill in the required parameters in the new item form:

| Item | Tags | Preprocessing |
|---------------------|---------------------------------|---------------|
| * Name | Interface wlp3s0: Bits received | |
| Type | SNMP agent | |
| * Key | net.if.in[ifHCInOctets.3] | |
| Type of information | Numeric (unsigned) | |
| * Host interface | 127.0.0.1:161 | |
| * SNMP OID ? | get[1.3.6.1.2.1.31.1.1.1.6.3] | |
| Units | bps | |
| * Update interval | 3m | |

| Parameter | Description |
|-----------------------|---|
| <i>Name</i> | Enter the item name. |
| <i>Type</i> | Select SNMP agent here. |
| <i>Key</i> | Enter the key as something meaningful. |
| <i>Host interface</i> | Make sure to select the SNMP interface, e.g. of your switch/router. |

| Parameter | Description |
|-----------------|--|
| <i>SNMP OID</i> | <p>Use one of the supported formats to enter OID value(s):</p> <p>walk[OID1,OID2,...] - retrieve a subtree of values. For example: walk[1.3.6.1.2.1.2.2.1.2,1.3.6.1.2.1.2.2.1.3]. This option makes use of native SNMP bulk requests (GetBulkRequest-PDUs) asynchronously. The timeout settings for this item can be set in the item configuration form. Consider setting a low timeout value to avoid long delays if the device is unreachable, as up to 5 retries (since Zabbix 7.2.8) will be made if earlier ones time out or fail (e.g., 3-second timeout can result in 15-second wait time). You may use this as the master item, with dependent items that extract data from the master using preprocessing. It is possible to specify multiple OIDs in a single snmp walk, such as walk[OID1,OID2,...] to asynchronously process one OID at a time. If the bulk request returns no results then it is attempted to retrieve a single record without bulk request. MIB names are supported as parameters; thus walk[1.3.6.1.2.1.2.2.1.2] and walk[ifDescr] will return the same output. If several OIDs/MIBs are specified, i.e. walk[ifDescr,ifType,ifPhysAddress], then the output is a concatenated list. GetBulk requests are used with SNMPv2 and v3 interfaces and GetNext for SNMPv1 interfaces; max repetitions for bulk requests are configured on the interface level. The max repetitions parameter affects bulk requests by determining the maximum number of OIDs returned in a single bulk response. A higher value results in larger bulk responses, reducing the number of transmissions required. However, not all devices might support very high values, which could cause issues. This item returns the output of the snmpwalk utility with -Oe -Ot -On parameters. You may use this item as a master item in SNMP discovery.</p> <p>get[OID] - retrieve a <i>single</i> value asynchronously. For example: get[1.3.6.1.2.1.31.1.1.1.6.3] The timeout settings for this item can be set in the item configuration form. Consider setting a low timeout value to avoid long delays if the device is unreachable, as up to 5 retries (since Zabbix 7.2.8) will be made if earlier ones time out or fail (e.g., 3-second timeout can result in 15-second wait time).</p> <p>OID - (legacy) enter a single textual or numeric OID to retrieve a single value synchronously, optionally combined with other values. For example: 1.3.6.1.2.1.31.1.1.1.6.3. For this option, the item check timeout will be equal to the value set in the server configuration file.</p> <p>It is recommended to use walk[OID] and get[OID] items for better performance. All walk[OID] and get[OID] items are executed asynchronously - it is not required to receive the response to one request before other checks are started. DNS resolving is asynchronous as well. The maximum concurrency of asynchronous checks is 1000 (defined by MaxConcurrentChecksPerPoller). The number of asynchronous SNMP pollers is defined by the StartSNMPPollers parameter.</p> <p>Note that for network traffic statistics, returned by any of the methods, a <i>Change per second</i> step must be added in the <i>Preprocessing</i> tab; otherwise you will get the cumulative value from the SNMP device instead of the latest change.</p> |

All mandatory input fields are marked with a red asterisk.

Now save the item and go to *Monitoring > Latest data* for your SNMP data.

Example 1

General example:

| Parameter | Description |
|------------|---|
| OID | 1.2.3.45.6.7.8.0 (or .1.2.3.45.6.7.8.0) |
| Key | <Unique string to be used as reference to triggers> For example, "my_param". |

Note that OID can be given in either numeric or string form. However, in some cases, string OID must be converted to numeric representation. Utility `snmpget` may be used for this purpose:

```
snmpget -On localhost public enterprises.ucdavis.memory.memTotalSwap.0
```

Example 2

Monitoring of uptime:

| Parameter | Description |
|--|------------------|
| OID | MIB::sysUpTime.0 |
| Key | router.uptime |
| Value type | Float |
| Units | uptime |
| Preprocessing step: Custom multiplier | 0.01 |

Native SNMP bulk requests

The **walk[OID1,OID2,...]** item allows to use native SNMP functionality for bulk requests (GetBulkRequest-PDUs), available in SNMP versions 2/3.

A GetBulk request in SNMP executes multiple GetNext requests and returns the result in a single response. This may be used for regular SNMP items as well as for SNMP discovery to minimize network roundtrips.

The SNMP **walk[OID1,OID2,...]** item may be used as the master item that collects data in one request with dependent items that parse the response as needed using preprocessing.

Note that using native SNMP bulk requests is not related to the option of combining SNMP requests, which is Zabbix own way of combining multiple SNMP requests (see next section).

A retry will occur for SNMP bulk items to avoid failure if one of the packets is lost. The timeout for SNMP items with `get` and `walk` (set in the `item configuration` form) is set for whole session. If the timeout is reached then a retry will occur, the timeout will be reset, and the last request will be resent allowing to continue the session from last request if a single packet is lost or arrived too late. Consider setting a low timeout value to avoid long delays if the device is unreachable, as up to 5 retries (since Zabbix 7.2.8) will be made if earlier ones time out or fail (e.g., 3-second timeout can result in 15-second wait time).

Internal workings of combined processing

Zabbix server and proxy may query SNMP devices for multiple values in a single request. This affects several types of SNMP items:

- regular SNMP items
- SNMP items **with dynamic indexes**
- SNMP **low-level discovery rules**

All SNMP items on a single interface with identical parameters are scheduled to be queried at the same time. The first two types of items are taken by pollers in batches of at most 128 items, whereas low-level discovery rules are processed individually, as before.

On the lower level, there are two kinds of operations performed for querying values: getting multiple specified objects and walking an OID tree.

For "getting", a GetRequest-PDU is used with at most 128 variable bindings. For "walking", a GetNextRequest-PDU is used for SNMPv1 and GetBulkRequest with "max-repetitions" field of at most 128 is used for SNMPv2 and SNMPv3.

Thus, the benefits of combined processing for each SNMP item type are outlined below:

- regular SNMP items benefit from "getting" improvements;
- SNMP items with dynamic indexes benefit from both "getting" and "walking" improvements: "getting" is used for index verification and "walking" for building the cache;
- SNMP low-level discovery rules benefit from "walking" improvements.

However, there is a technical issue that not all devices are capable of returning 128 values per request. Some always return a proper response, but others either respond with a "tooBig(1)" error or do not respond at all once the potential response is over a certain limit.

In order to find an optimal number of objects to query for a given device, Zabbix uses the following strategy. It starts cautiously with querying 1 value in a request. If that is successful, it queries 2 values in a request. If that is successful again, it queries 3 values in a request and continues similarly by multiplying the number of queried objects by 1.5, resulting in the following sequence of request sizes: 1, 2, 3, 4, 6, 9, 13, 19, 28, 42, 63, 94, 128.

However, once a device refuses to give a proper response (for example, for 42 variables), Zabbix does two things.

First, for the current item batch it halves the number of objects in a single request and queries 21 variables. If the device is alive, then the query should work in the vast majority of cases, because 28 variables were known to work and 21 is significantly less than that. However, if that still fails, then Zabbix falls back to querying values one by one. If it still fails at this point, then the device is definitely not responding and request size is not an issue.

The second thing Zabbix does for subsequent item batches is it starts with the last successful number of variables (28 in our example) and continues incrementing request sizes by 1 until the limit is hit. For example, assuming the largest response size is 32 variables, the subsequent requests will be of sizes 29, 30, 31, 32, and 33. The last request will fail and Zabbix will never issue a request of size 33 again. From that point on, Zabbix will query at most 32 variables for this device.

If large queries fail with this number of variables, it can mean one of two things. The exact criteria that a device uses for limiting response size cannot be known, but we try to approximate that using the number of variables. So the first possibility is that this number of variables is around the device's actual response size limit in the general case: sometimes response is less than the limit, sometimes it is greater than that. The second possibility is that a UDP packet in either direction simply got lost. For these reasons, if Zabbix gets a failed query, it reduces the maximum number of variables to try to get deeper into the device's comfortable range, but only up to two times.

In the example above, if a query with 32 variables happens to fail, Zabbix will reduce the count to 31. If that happens to fail, too, Zabbix will reduce the count to 30. However, Zabbix will not reduce the count below 30, because it will assume that further failures are due to UDP packets getting lost, rather than the device's limit.

If, however, a device cannot handle combined requests properly for other reasons and the heuristic described above does not work, there is a "Use combined requests" setting for each interface that allows to disable combined requests for that device.

Additionally, if the interface frequently becomes unavailable, it may be necessary to increase the `UnavailableDelay` parameter in the **Zabbix server** or **Zabbix proxy** configuration files to reduce the frequency of requests. Items may become unsupported if partial data is received during discovery or OID walks.

1 Dynamic indexes

Overview

While you may find the required index number (for example, of a network interface) among the SNMP OIDs, sometimes you may not completely rely on the index number always staying the same.

Index numbers may be dynamic - they may change over time and your item may stop working as a consequence.

To avoid this scenario, it is possible to define an OID which takes into account the possibility of an index number changing.

For example, if you need to retrieve the index value to append to **ifInOctets** that corresponds to the **GigabitEthernet0/1** interface on a Cisco device, use the following OID:

```
ifInOctets["index","ifDescr","GigabitEthernet0/1"]
```

The syntax

A special syntax for OID is used:

<OID of data>["index","<base OID of index>","<string to search for>"]

| Parameter | Description |
|----------------------|---|
| OID of data | Main OID to use for data retrieval on the item. |
| index | Method of processing. Currently one method is supported: index - search for index and append it to the data OID |
| base OID of index | This OID will be looked up to get the index value corresponding to the string. |
| string to search for | The string to use for an exact match with a value when doing lookup. Case sensitive. |

Example

Getting memory usage of *apache* process.

If using this OID syntax:

```
HOST-RESOURCES-MIB::hrSWRunPerfMem["index", "HOST-RESOURCES-MIB::hrSWRunPath", "/usr/sbin/apache2"]
```

the index number will be looked up here:

```
...
HOST-RESOURCES-MIB::hrSWRunPath.5376 = STRING: "/sbin/getty"
HOST-RESOURCES-MIB::hrSWRunPath.5377 = STRING: "/sbin/getty"
HOST-RESOURCES-MIB::hrSWRunPath.5388 = STRING: "/usr/sbin/apache2"
HOST-RESOURCES-MIB::hrSWRunPath.5389 = STRING: "/sbin/sshd"
...
```

Now we have the index, 5388. The index will be appended to the data OID in order to receive the value we are interested in:

```
HOST-RESOURCES-MIB::hrSWRunPerfMem.5388 = INTEGER: 31468 KBytes
```

Index lookup caching

When a dynamic index item is requested, Zabbix retrieves and caches whole SNMP table under base OID for index, even if a match would be found sooner. This is done in case another item would refer to the same base OID later - Zabbix would look up index in the cache, instead of querying the monitored host again. Note that each poller process uses separate cache.

In all subsequent value retrieval operations only the found index is verified. If it has not changed, value is requested. If it has changed, cache is rebuilt - each poller that encounters a changed index walks the index SNMP table again.

2 Special OIDs

Some of the most used SNMP OIDs are translated automatically to a numeric representation by Zabbix. For example, **ifIndex** is translated to **1.3.6.1.2.1.2.2.1.1**, **ifIndex.0** is translated to **1.3.6.1.2.1.2.2.1.1.0**.

The table contains list of the special OIDs.

| Special OID | Identifier | Description |
|-------------------|----------------------|---|
| ifIndex | 1.3.6.1.2.1.2.2.1.1 | A unique value for each interface. |
| ifDescr | 1.3.6.1.2.1.2.2.1.2 | A textual string containing information about the interface. This string should include the name of the manufacturer, the product name and the version of the hardware interface. |
| ifType | 1.3.6.1.2.1.2.2.1.3 | The type of interface, distinguished according to the physical/link protocol(s) immediately 'below' the network layer in the protocol stack. |
| ifMtu | 1.3.6.1.2.1.2.2.1.4 | The size of the largest datagram which can be sent / received on the interface, specified in octets. |
| ifSpeed | 1.3.6.1.2.1.2.2.1.5 | An estimate of the interface's current bandwidth in bits per second. |
| ifPhysAddress | 1.3.6.1.2.1.2.2.1.6 | The interface's address at the protocol layer immediately 'below' the network layer in the protocol stack. |
| ifAdminStatus | 1.3.6.1.2.1.2.2.1.7 | The current administrative state of the interface. |
| ifOperStatus | 1.3.6.1.2.1.2.2.1.8 | The current operational state of the interface. |
| ifInOctets | 1.3.6.1.2.1.2.2.1.10 | The total number of octets received on the interface, including framing characters. |
| ifInUcastPkts | 1.3.6.1.2.1.2.2.1.11 | The number of subnetwork-unicast packets delivered to a higher-layer protocol. |
| ifInNUcastPkts | 1.3.6.1.2.1.2.2.1.12 | The number of non-unicast (i.e., subnetwork- broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. |
| ifInDiscards | 1.3.6.1.2.1.2.2.1.13 | The number of inbound packets which were chosen to be discarded even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. |
| ifInErrors | 1.3.6.1.2.1.2.2.1.14 | The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. |
| ifInUnknownProtos | 1.3.6.1.2.1.2.2.1.15 | The number of packets received via the interface which were discarded because of an unknown or unsupported protocol. |
| ifOutOctets | 1.3.6.1.2.1.2.2.1.16 | The total number of octets transmitted out of the interface, including framing characters. |
| ifOutUcastPkts | 1.3.6.1.2.1.2.2.1.17 | The total number of packets that higher-level protocols requested be transmitted, and which were not addressed to a multicast or broadcast address at this sub-layer, including those that were discarded or not sent. |

| Special OID | Identifier | Description |
|-----------------|----------------------|---|
| ifOutNUcastPkts | 1.3.6.1.2.1.2.2.1.18 | The total number of packets that higher-level protocols requested be transmitted, and which were addressed to a multicast or broadcast address at this sub-layer, including those that were discarded or not sent. |
| ifOutDiscards | 1.3.6.1.2.1.2.2.1.19 | The number of outbound packets which were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. |
| ifOutErrors | 1.3.6.1.2.1.2.2.1.20 | The number of outbound packets that could not be transmitted because of errors. |
| ifOutQLen | 1.3.6.1.2.1.2.2.1.21 | The length of the output packet queue (in packets). |

3 MIB files

Introduction

MIB stands for the Management Information Base. MIB files allow to use textual representation of an OID (Object Identifier). It is possible to use raw OIDs when monitoring SNMP devices with Zabbix, but if you feel more comfortable using textual representation, you need to install MIB files.

For example,

`ifHCOutOctets`

is textual representation of the OID

`1.3.6.1.2.1.31.1.1.1.10`

Installing MIB files

On Debian-based systems:

```
apt install snmp-mibs-downloader
download-mibs
```

On RedHat-based systems:

```
dnf install net-snmp-libs
```

Enabling MIB files

On RedHat-based systems, MIB files should be enabled by default. On Debian-based systems, you have to edit the file `/etc/snmp/snmp.conf` and comment out the line that says `mibs :`

```
# As the snmp packages come without MIB files due to license reasons, loading
# of MIBs is disabled by default. If you added the MIBs you can re-enable
# loading them by commenting out the following line.
mibs :
```

Testing MIB files

Testing SNMP MIBs can be done using `snmpwalk` utility. If you don't have it installed, use the following instructions.

On Debian-based systems:

```
apt install snmp
```

On RedHat-based systems:

```
dnf install net-snmp-utils
```

After that, the following command must not give error when you query a network device:

```
$ snmpwalk -v 2c -c public <NETWORK DEVICE IP> ifInOctets
IF-MIB::ifInOctets.1 = Counter32: 176137634
IF-MIB::ifInOctets.2 = Counter32: 0
IF-MIB::ifInOctets.3 = Counter32: 240375057
IF-MIB::ifInOctets.4 = Counter32: 220893420
[...]
```

Using MIBs in Zabbix

The most important to keep in mind is that Zabbix processes do not get informed of the changes made to MIB files. So after every change you must restart Zabbix server or proxy, e. g.:

```
systemctl restart zabbix-server
```

After that, the changes made to MIB files are in effect.

Using custom MIB files

There are standard MIB files coming with every GNU/Linux distribution. But some device vendors provide their own.

Let's say, you would like to use **CISCO-SMI** MIB file. The following instructions will download and install it:

```
wget ftp://ftp.cisco.com/pub/mibs/v2/CISCO-SMI.my -P /tmp
mkdir -p /usr/local/share/snmp/mibs
grep -q '^mibdirs +/usr/local/share/snmp/mibs' /etc/snmp/snmp.conf 2>/dev/null || echo "mibdirs +/usr/local/share/snmp/mibs" >> /etc/snmp/snmp.conf
cp /tmp/CISCO-SMI.my /usr/local/share/snmp/mibs
```

Now you should be able to use it. Try to translate the name of the object *ciscoProducts* from the MIB file to OID:

```
snmptranslate -IR -On CISCO-SMI::ciscoProducts
.1.3.6.1.4.1.9.1
```

If you receive errors instead of the OID, ensure all the previous commands did not return any errors.

The object name translation worked, you are ready to use custom MIB file. Note the MIB name prefix (*CISCO-SMI::*) used in the query. You will need this when using command-line tools as well as Zabbix.

Don't forget to restart Zabbix server/proxy before using this MIB file in Zabbix.

Attention:

Keep in mind that MIB files can have dependencies. That is, one MIB may require another. In order to satisfy these dependencies you have to install all the affected MIB files.

3 SNMP traps

Overview

Receiving SNMP traps is the opposite to querying SNMP-enabled devices.

In this case, the information is sent from an SNMP-enabled device to **snmptrapd** and is collected or "trapped" by Zabbix server or Zabbix proxy from file.

Usually, traps are sent upon some condition change and the agent connects to the server on port 162 (as opposed to port 161 on the agent side that is used for queries). Using traps may detect some short problems that occur amidst the query interval and may be missed by the query data.

Receiving SNMP traps in Zabbix is designed to work with **snmptrapd** and one of the mechanisms for passing the traps to Zabbix - either a Bash or Perl script or SNMPTT.

Note:

The simplest way to set up trap monitoring after configuring Zabbix is to use the Bash script solution, because Perl and SNMPTT are often missing in modern distributions and require more complex configuration. However, this solution uses a script configured as **traphandle**. For better performance on production systems, use the embedded Perl solution (either script with **do perl** option or SNMPTT).

The workflow of receiving a trap:

1. **snmptrapd** receives a trap
2. **snmptrapd** passes the trap to the receiver script (Bash, Perl) or SNMPTT
3. The receiver parses, formats and writes the trap to a file
4. Zabbix SNMP trapper reads and parses the trap file
5. For each trap Zabbix finds all "SNMP trapper" items with host interfaces matching the received trap address. Note that only the selected "IP" or "DNS" in host interface is used during the matching.
6. For each found item, the trap is compared to regexp in **snmptrap[regexp]**. The trap is set as the value of **all** matched items. If no matching item is found and there is an **snmptrap.fallback** item, the trap is set as the value of that.
7. If the trap was not set as the value of any item, Zabbix by default logs the unmatched trap. (This is configured by "Log unmatched SNMP traps" in Administration > General > Other.)

Notes on HA failover

During high-availability (HA) node switch, Zabbix will continue processing after the last record within the last ISO 8601 timestamp; if the same record is not found then only the timestamp will be used to identify last position.

Configuring SNMP traps

This item type requires the following frontend configuration.

- 1. Create an SNMP interface for your host
 - In *Data collection > Hosts*, create/edit the host, and in the *Interfaces* field, add the interface type "SNMP", specifying the IP or DNS address.

The address from each received trap will be compared to the IP and DNS addresses of all SNMP interfaces to find the corresponding hosts.
- 2. Configure the item
 - In *Data collection > Hosts*, create/edit the necessary item.
 - In the *Key* field, use one of the SNMP trap keys:

| Key | | |
|---|--------------|--|
| Description | Return value | Comments |
| snmptrap[regexp] Catches all SNMP traps that match the regular expression specified in regexp . If regexp is unspecified, catches any trap. | SNMP trap | This item can be set only for SNMP interfaces. User macros and global regular expressions are supported in the parameter of this item key. |
| snmptrap.fallback Catches all SNMP traps that were not caught by any of the snmptrap[] items for that interface. | SNMP trap | This item can be set only for SNMP interfaces. |

Note:

Multiline regular expression matching is not supported at this time.

- Set the *Type of information* to "Log" for the timestamps to be parsed. Other formats such as "Numeric" are also acceptable but might require a custom trap handler.

Setting up SNMP trap monitoring

Configuring Zabbix server/proxy

To read the traps, Zabbix server or proxy must be configured to start the SNMP trapper process and point to the trap file that is being written by SNMPTT or a Bash/Perl trap receiver. To do that, edit the configuration file (*zabbix_server.conf* or *zabbix_proxy.conf*):

```
StartSNMPTrapper=1
SNMPTrapperFile=[TRAP FILE]
```

Warning:

If systemd parameter **PrivateTmp** is used, this file is unlikely to work in */tmp*.

Configuring Bash trap receiver

Requirements: only snmptrapd.

A Bash trap receiver [script](#) can be used to pass traps to Zabbix server from snmptrapd using trapper file. To configure it, add the `traphandle` option to snmptrapd configuration file (*snmptrapd.conf*), see [example](#).

Note:

snmptrapd might need to be restarted to pick up changes to its configuration.

Configuring Perl trap receiver

Requirements: Perl, Net-SNMP compiled with --enable-embedded-perl (done by default since Net-SNMP 5.4)

A Perl trap receiver (look for misc/snmptrap/zabbix_trap_receiver.pl) can be used to pass traps to Zabbix server directly from snmptrapd. To configure it:

- add the Perl script to the snmptrapd configuration file (snmptrapd.conf), e.g.:

```
perl do "[FULL PATH TO PERL RECEIVER SCRIPT]";
```

- configure the receiver, e.g:

```
$SNMPTrapperFile = '[TRAP FILE]';  
$DateTimeFormat = '[DATE TIME FORMAT]';
```

Note:

snmptrapd might need to be restarted to pick up changes to its configuration.

Note:

If the script name is not quoted, snmptrapd will refuse to start up with messages, similar to these:

Regexp modifiers "/l" and "/a" are mutually exclusive at (eval 2) line 1, at end of line
Regexp modifier "/l" may not appear twice at (eval 2) line 1, at end of line

Configuring SNMPPTT

At first, snmptrapd should be configured to use SNMPPTT.

Note:

For the best performance, SNMPPTT should be configured as a daemon using **snmpthandler-embedded** to pass the traps to it. See instructions for [configuring SNMPPTT](#).

When SNMPPTT is configured to receive the traps, configure snmptt.ini:

1. enable the use of the Perl module from the NET-SNMP package:

```
net_snmp_perl_enable = 1
```

2. log traps to the trap file which will be read by Zabbix:

```
log_enable = 1  
log_file = [TRAP FILE]
```

3. set the date-time format:

```
date_time_format = %Y-%m-%dT%H:%M:%S%z
```

Warning:

The "net-snmp-perl" package has been removed in RHEL 8.0-8.2; re-added in RHEL 8.3. For more information, see the [known issues](#).

Now format the traps for Zabbix to recognize them (edit snmptt.conf):

1. Each FORMAT statement should start with "ZBXTRAP [address]", where [address] will be compared to IP and DNS addresses of SNMP interfaces on Zabbix. E.g.:

```
EVENT coldStart .1.3.6.1.6.3.1.1.5.1 "Status Events" Normal  
FORMAT ZBXTRAP $aA Device reinitialized (coldStart)
```

2. See more about SNMP trap format below.

Attention:

Do not use unknown traps - Zabbix will not be able to recognize them. Unknown traps can be handled by defining a general event in snmptt.conf:

```
EVENT general .* "General event" Normal
```

SNMP trap format

All customized Perl trap receivers and SNMPPTT trap configuration must format the trap in the following way:

```
[timestamp] [the trap, part 1] ZBXTRAP [address] [the trap, part 2]
```

where

- [timestamp] - the timestamp in “%Y-%m-%dT%H:%M:%S%z” format
- ZBXTRAP - header that indicates that a new trap starts in this line
- [address] - IP address used to find the host for this trap

Note that “ZBXTRAP” and “[address]” will be cut out from the message during processing. If the trap is formatted otherwise, Zabbix might parse the traps unexpectedly.

Example trap:

```
2024-01-11T15:28:47+0200 .1.3.6.1.6.3.1.1.5.3 Normal "Status Events" localhost - ZBXTRAP 192.168.1.1 Link
```

This will result in the following trap for SNMP interface with IP=192.168.1.1:

```
2024-01-11T15:28:47+0200 .1.3.6.1.6.3.1.1.5.3 Normal "Status Events"
localhost - Link down on interface 2. Admin state: 1. Operational state: 2
```

System requirements

Note:

It is recommended to **install MIB files** to ensure that item values are displayed in the correct format. Without the MIB files, formatting issues, such as displaying values in HEX instead of UTF-8 or vice versa, may occur.

Large file support

Zabbix has large file support for SNMP trapper files. The maximum file size that Zabbix can read is 2^{63} (8 EiB). Note that the filesystem may impose a lower limit on the file size.

Log rotation

Zabbix does not provide any log rotation system - that should be handled by the user. The log rotation should first rename the old file and only later delete it so that no traps are lost:

1. Zabbix opens the trap file at the last known location and goes to step 3
2. Zabbix checks if the currently opened file has been rotated by comparing the inode number to the defined trap file's inode number. If there is no opened file, Zabbix resets the last location and goes to step 1.
3. Zabbix reads the data from the currently opened file and sets the new location.
4. The new data are parsed. If this was the rotated file, the file is closed and goes back to step 2.
5. If there was no new data, Zabbix sleeps for 1 second and goes back to step 2.

File system

Because of the trap file implementation, Zabbix needs the file system to support inodes to differentiate files (the information is acquired by a `stat()` call).

Setup examples using different SNMP protocol versions

This example uses `snmptrapd` and a Bash receiver script to pass traps to Zabbix server.

Setup:

1. Configure Zabbix to start SNMP trapper and set the trap file. Add to `zabbix_server.conf`:

```
StartSNMPTrapper=1
SNMPTrapperFile=/var/lib/zabbix/snmptraps/snmptraps.log
```

2. Download the Bash script to `/usr/sbin/zabbix_trap_handler.sh`:

```
curl -o /usr/sbin/zabbix_trap_handler.sh https://raw.githubusercontent.com/zabbix/zabbix-docker/trunk/Dock
```

If necessary, adjust the `ZABBIX_TRAPS_FILE` variable in the script. To use the default value, create the parent directory first:

```
mkdir -p /var/lib/zabbix/snmptraps
```

3. Add the following to `snmptrapd.conf` (refer to working [example](#))

```
traphandle default /bin/bash /usr/sbin/zabbix_trap_handler.sh
```

Note:

snmptrapd might need to be restarted to pick up changes to its configuration.

4. **Create** an SNMP item TEST (keep in mind the initial **configuration requirements**):

```
Type: SNMP trap
Type of information: Log Host interface: SNMP 127.0.0.1
Key: snmptrap["linkUp"]
Log time format: yyyyMMdd.hhmmss
```

Note that the ISO 8601 date and time format is used.

5. Next we will configure `snmptrapd` for our chosen SNMP protocol version and send test traps using the `snmptrap` utility.

SNMPv1, SNMPv2

SNMPv1 and SNMPv2 protocols rely on "community string" authentication. In the example below we will use "secret" as community string. It must be set to the same value on SNMP trap senders.

Please note that while still widely used in production environments, SNMPv2 doesn't offer any encryption and real sender authentication. The data is sent as plain text and therefore these protocol versions should only be used in secure environments such as private network and should never be used over any public or third-party network.

SNMP version 1 isn't really used these days since it doesn't support 64-bit counters and is considered a legacy protocol.

To enable accepting SNMPv1 or SNMPv2 traps you should add the following line to `snmptrapd.conf`. Replace "secret" with the SNMP community string configured on SNMP trap senders:

```
authCommunity log,execute,net secret
```

Next we can send a test trap using `snmptrap`. We will use the common "link up" OID in this example:

```
snmptrap -v 2c -c secret localhost ' ' linkUp.0
```

SNMPv3

SNMPv3 addresses SNMPv1/v2 security issues and provides authentication and encryption. You can use the MD5 or multiple SHA authentication methods and DES/multiple AES as cipher.

To enable accepting SNMPv3 add the following lines to `snmptrapd.conf`:

```
createUser -e 0x8000000001020304 traptest SHA mypassword AES
authuser log,execute traptest
```

Attention:

Please note the "execute" keyword that allows to execute scripts for this user security model.

```
snmptrap -v 3 -n "" -a SHA -A mypassword -x AES -X mypassword -l authPriv -u traptest -e 0x8000000001020304
```

Warning:

If you wish to use strong encryption methods such as AES192 or AES256, please use `net-snmp` starting with version 5.8. You might have to recompile it with configure option: `--enable-blumenthal-aes`. Older versions of `net-snmp` do not support AES192/AES256. See also: [Strong Authentication or Encryption](#).

Verification

In both examples you will see similar lines in your `/var/lib/zabbix/snmptraps/snmptraps.log`:

```
2024-01-30T10:04:23+0200 ZBXTRAP 127.0.0.1
UDP: [127.0.0.1]:56585->[127.0.0.1]:162
DISMAN-EVENT-MIB::sysUpTimeInstance = 2538834
SNMPv2-MIB::snmpTrapOID.0 = IF-MIB::linkUp.0
```

The item value in Zabbix will be:

```
2024-01-30 10:04:23 2024-01-30 10:04:21
```

```
2024-01-30T10:04:21+0200 UDP: [127.0.0.1]:56585->[127.0.0.1]:162
```

```
DISMAN-EVENT-MIB::sysUpTimeInstance = 2538834
SNMPv2-MIB::snmpTrapOID.0 = IF-MIB::linkUp.0
```

Example with Perl:

```
2024-01-30T11:42:54+0200 ZBXTRAP 127.0.0.1
```

PDU INFO:

| | |
|------------------|---|
| receivedfrom | UDP: [127.0.0.1]:58649->[127.0.0.1]:162 |
| notificationtype | TRAP |

4 IPMI checks

Overview

You can monitor the health and availability of Intelligent Platform Management Interface (IPMI) devices in Zabbix. To perform IPMI checks Zabbix server must be initially **configured** with IPMI support.

IPMI is a standardized interface for remote "lights-out" or "out-of-band" management of computer systems. It allows to monitor hardware status directly from the so-called "out-of-band" management cards, independently from the operating system or whether the machine is powered on at all.

Zabbix IPMI monitoring works only for devices having IPMI support (HP iLO, DELL DRAC, IBM RSA, Sun SSP, etc).

An IPMI manager process schedules the IPMI checks by IPMI pollers. A host is always polled by only one IPMI poller at a time, reducing the number of open connections to BMC controllers. Thus it's safe to increase the number of IPMI pollers without worrying about BMC controller overloading. The IPMI manager process is automatically started when at least one IPMI poller is started.

See also **known issues** for IPMI checks.

Configuration

Host configuration

A host must be configured to process IPMI checks. An IPMI interface must be added, with the respective IP and port numbers, and IPMI authentication parameters must be defined.

See the **configuration of hosts** for more details.

Server configuration

By default, the Zabbix server is not configured to start any IPMI pollers, thus any added IPMI items won't work. To change this, open the Zabbix server configuration file (**zabbix_server.conf**) as root and look for the following line:

```
# StartIPMIPollers=0
```

Uncomment it and set poller count to, say, 3, so that it reads:

```
StartIPMIPollers=3
```

Save the file and restart zabbix_server afterwards.

Item configuration

When **configuring an item** on a host level:

- Select 'IPMI agent' as the *Type*

- Enter an item **key** that is unique within the host (say, ipmi.fan.rpm)
- For *Host interface* select the relevant IPMI interface (IP and port). Note that an IPMI interface must exist on the host.
- Specify the *IPMI sensor* (for example 'FAN MOD 1A RPM' on Dell Poweredge) to retrieve the metric from. By default, the sensor ID should be specified. It is also possible to use prefixes before the value:
 - **id:** - to specify sensor ID;
 - **name:** - to specify sensor full name. This can be useful in situations when sensors can only be distinguished by specifying the full name.
- Select the respective type of information ('Numeric (float)' in this case; for discrete sensors - 'Numeric (unsigned)'), units (most likely 'rpm') and any other required item attributes

Supported checks

IPMI agent supports the built-in item **ipmi.get**, which returns IPMI-sensor related information and can be used for the **discovery of IPMI sensors**.

Return value: *JSON object*

Timeout and session termination

IPMI message timeouts and retry counts are defined in OpenIPMI library. Due to the current design of OpenIPMI, it is not possible to make these values configurable in Zabbix, neither on interface nor item level.

IPMI session inactivity timeout for LAN is 60 +/-3 seconds. Currently it is not possible to implement periodic sending of Activate Session command with OpenIPMI. If there are no IPMI item checks from Zabbix to a particular BMC for more than the session timeout configured in BMC then the next IPMI check after the timeout expires will time out due to individual message timeouts, retries or receive error. After that a new session is opened and a full rescan of the BMC is initiated. A new UDP port may be opened to manage the new session. Inactivity is defined by the absence of both outgoing requests and incoming responses. If you want to avoid unnecessary rescans of the BMC it is advised to set the IPMI item polling interval below the IPMI session inactivity timeout configured in BMC.

Notes on IPMI discrete sensors

To find sensors on a host start Zabbix server with **DebugLevel=4** enabled. Wait a few minutes and find sensor discovery records in Zabbix server logfile:

```
$ grep 'Added sensor' zabbix_server.log
8358:20130318:111122.170 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:7 id:'CATERR' reading_type:
8358:20130318:111122.170 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:15 id:'CPU Therm Trip' read
8358:20130318:111122.171 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:17 id:'System Event Log' re
8358:20130318:111122.171 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:17 id:'PhysicalSecurity' re
8358:20130318:111122.171 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:14 id:'IPMI Watchdog' readi
8358:20130318:111122.171 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:16 id:'Power Unit Stat' rea
8358:20130318:111122.171 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:16 id:'P1 Therm Ctrl %' rea
8358:20130318:111122.172 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:16 id:'P1 Therm Margin' rea
8358:20130318:111122.172 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:13 id:'System Fan 2' readin
8358:20130318:111122.172 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:13 id:'System Fan 3' readin
8358:20130318:111122.172 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:14 id:'P1 Mem Margin' readi
8358:20130318:111122.172 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:17 id:'Front Panel Temp' re
8358:20130318:111122.173 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:15 id:'Baseboard Temp' read
8358:20130318:111122.173 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:9 id:'BB +5.0V' reading_typ
8358:20130318:111122.173 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:14 id:'BB +3.3V STBY' readi
8358:20130318:111122.173 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:9 id:'BB +3.3V' reading_typ
8358:20130318:111122.173 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:17 id:'BB +1.5V P1 DDR3' re
8358:20130318:111122.173 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:17 id:'BB +1.1V P1 Vccp' re
8358:20130318:111122.174 Added sensor: host:'192.168.1.12:623' id_type:0 id_sz:14 id:'BB +1.05V PCH' readi
```

To decode IPMI sensor types and states, a copy of [IPMI 2.0 specifications](#) is available (please note that **no further updates** to the IPMI specification are planned).

The first parameter to start with is "reading_type". Use "Table 42-1, Event/Reading Type Code Ranges" from the specifications to decode "reading_type" code. Most of the sensors in our example have "reading_type:0x1" which means "threshold" sensor. "Table 42-3, Sensor Type Codes" shows that "type:0x1" means temperature sensor, "type:0x2" - voltage sensor, "type:0x4" - Fan etc. Threshold sensors sometimes are called "analog" sensors as they measure continuous parameters like temperature, voltage, revolutions per minute.

Another example - a sensor with "reading_type:0x3". "Table 42-1, Event/Reading Type Code Ranges" says that reading type codes 02h-0Ch mean "Generic Discrete" sensor. Discrete sensors have up to 15 possible states (in other words - up to 15 meaningful bits). For example, for sensor 'CATERR' with "type:0x7" the "Table 42-3, Sensor Type Codes" shows that this type means "Processor" and the meaning of individual bits is: 00h (the least significant bit) - IERR, 01h - Thermal Trip etc.

There are few sensors with "reading_type:0x6f" in our example. For these sensors the "Table 42-1, Event/Reading Type Code Ranges" advises to use "Table 42-3, Sensor Type Codes" for decoding meanings of bits. For example, sensor 'Power Unit Stat' has type "type:0x9" which means "Power Unit". Offset 00h means "PowerOff/Power Down". In other words if the least significant bit is 1, then server is powered off. To test this bit, the **bitand** function with mask '1' can be used. The trigger expression could be like

```
bitand(last(/www.example.com/Power Unit Stat,#1),1)=1
```

to warn about a server power off.

Notes on discrete sensor names in OpenIPMI-2.0.16, 2.0.17, 2.0.18 and 2.0.19

Names of discrete sensors in OpenIPMI-2.0.16, 2.0.17 and 2.0.18 often have an additional "0" (or some other digit or letter) appended at the end. For example, while ipmitool and OpenIPMI-2.0.19 display sensor names as "PhysicalSecurity" or "CATERR", in OpenIPMI-2.0.16, 2.0.17 and 2.0.18 the names are "PhysicalSecurity0" or "CATERR0", respectively.

When configuring an IPMI item with Zabbix server using OpenIPMI-2.0.16, 2.0.17 and 2.0.18, use these names ending with "0" in the *IPMI sensor* field of IPMI agent items. When your Zabbix server is upgraded to a new Linux distribution, which uses OpenIPMI-2.0.19 (or later), items with these IPMI discrete sensors will become "NOT SUPPORTED". You have to change their *IPMI sensor* names (remove the '0' in the end) and wait for some time before they turn "Enabled" again.

Notes on threshold and discrete sensor simultaneous availability

Some IPMI agents provide both a threshold sensor and a discrete sensor under the same name. The preference is always given to the threshold sensor.

Notes on connection termination

If IPMI checks are not performed (by any reason: all host IPMI items disabled/notsupported, host disabled/deleted, host in maintenance etc.) the IPMI connection will be terminated from Zabbix server or proxy in 3 to 4 hours depending on the time when Zabbix server/proxy was started.

5 Simple checks

Overview

Simple checks are normally used for remote agent-less checks of services.

Note that Zabbix agent is not needed for simple checks. Zabbix server/proxy is responsible for the processing of simple checks (making external connections, etc).

Examples of using simple checks:

```
net.tcp.service[ftp,,155]
net.tcp.service[http]
net.tcp.service.perf[http,,8080]
net.udp.service.perf[ntp]
```

Note:

User name and *Password* fields (limited to 255 characters) in simple check item configuration are used for VMware monitoring items; ignored otherwise.

Supported checks

The item keys are listed without optional parameters and additional information. Click on the item key to see the full details.

See also [VMware monitoring item keys](#).

| Item key | Description |
|--------------------------------------|--|
| icmping | The host accessibility by ICMP ping. |
| icmpingloss | The percentage of lost packets. |
| icmpingsec | The ICMP ping response time. |
| net.tcp.service | Checks if a service is running and accepting TCP connections. |
| net.tcp.service.perf | Checks the performance of a TCP service. |
| net.udp.service | Checks if a service is running and responding to UDP requests. |
| net.udp.service.perf | Checks the performance of a UDP service. |

Item key details

Parameters without angle brackets are mandatory. Parameters marked with angle brackets < > are optional.

icmpping[<target>,<packets>,<interval>,<size>,<timeout>,<options>]

 The host accessibility by ICMP ping.
 Return value: *0* - ICMP ping fails; *1* - ICMP ping successful.

Parameters:

- **target** - the host IP or DNS name;
- **packets** - the number of packets;
- **interval** - the time between successive packets in milliseconds;
- **size** - the packet size in bytes;
- **timeout** - the timeout in milliseconds;
- **options** - used for allowing redirect: if empty (default value), redirected responses are treated as target host down; if set to *allow_redirect*, redirected responses are treated as target host up.

See also the table of [default values](#).

Example:

```
icmpping[,4] #If at least one packet of the four is returned, the item will return 1.
```

icmppingloss[<target>,<packets>,<interval>,<size>,<timeout>,<options>]

 The percentage of lost packets.
 Return value: *Float*.

Parameters:

- **target** - the host IP or DNS name;
- **packets** - the number of packets;
- **interval** - the time between successive packets in milliseconds;
- **size** - the packet size in bytes;
- **timeout** - the timeout in milliseconds;
- **options** - used for allowing redirect: if empty (default value), redirected responses are treated as target host down; if set to *allow_redirect*, redirected responses are treated as target host up.

See also the table of [default values](#).

icmppingsec[<target>,<packets>,<interval>,<size>,<timeout>,<mode>,<options>]

 The ICMP ping response time (in seconds).
 Return value: *Float*.

Parameters:

- **target** - the host IP or DNS name;
- **packets** - the number of packets;
- **interval** - the time between successive packets in milliseconds;
- **size** - the packet size in bytes;
- **timeout** - the timeout in milliseconds;
- **mode** - possible values: *min*, *max*, or *avg* (default);
- **options** - used for allowing redirect: if empty (default value), redirected responses are treated as target host down; if set to *allow_redirect*, redirected responses are treated as target host up.

Comments:

- Packets which are lost or timed out are not used in the calculation;
- If the host is not available (timeout reached), the item will return 0;
- If the return value is less than 0.0001 seconds, the value will be set to 0.0001 seconds;
- See also the table of [default values](#).

net.tcp.service[service,<ip>,<port>]

 Checks if a service is running and accepting TCP connections.
 Return value: *0* - the service is down; *1* - the service is running.

Parameters:

- **service** - possible values: *ssh*, *ldap*, *smtp*, *ftp*, *http*, *pop*, *nntp*, *imap*, *tcp*, *https*, *telnet* (see [details](#));
- **ip** - the IP address or DNS name (by default the host IP/DNS is used);
- **port** - the port number (by default the standard service port number is used).

Comments:

- Note that with *tcp* service indicating the port is mandatory;
- These checks may result in additional messages in system daemon logfiles (SMTP and SSH sessions being logged usually);

- Checking of encrypted protocols (like IMAP on port 993 or POP on port 995) is currently not supported. As a workaround, please use `net.tcp.service[tcp,<ip>,<port>]` for checks like these.

Example:

```
net.tcp.service[ftp,,45] #This item can be used to test the availability of FTP server on TCP port 45.
```

Attention:

If SELinux is running in enforced mode, custom TCP/UDP simple checks may be blocked by the policy. To verify and allow the new outgoing connection, review audit denials: with `grep denied /var/log/audit/audit.log`

```
net.tcp.service.perf[service,<ip>,<port>]
```

 Checks the performance of a TCP service.
 Return value: *Float*: 0.000000 - the service is down; *seconds* - the number of seconds spent while connecting to the service.

Parameters:

- **service** - possible values: *ssh, ldap, smtp, ftp, http, pop, nntp, imap, tcp, https, telnet* (see [details](#));
- **ip** - the IP address or DNS name (by default the host IP/DNS is used);
- **port** - the port number (by default the standard service port number is used).

Comments:

- Note that with *tcp* service indicating the port is mandatory;
- Checking of encrypted protocols (like IMAP on port 993 or POP on port 995) is currently not supported. As a workaround, please use `net.tcp.service[tcp,<ip>,<port>]` for checks like these.

Example:

```
net.tcp.service.perf[ssh] #This item can be used to test the speed of initial response from SSH server.
```

```
net.udp.service[service,<ip>,<port>]
```

 Checks if a service is running and responding to UDP requests.
 Return value: 0 - the service is down; 1 - the service is running.

Parameters:

- **service** - possible values: *ntp* (see [details](#));
- **ip** - the IP address or DNS name (by default the host IP/DNS is used);
- **port** - the port number (by default the standard service port number is used).

Example:

```
net.udp.service[ntp,,45] #This item can be used to test the availability of NTP service on UDP port 45.
```

```
net.udp.service.perf[service,<ip>,<port>]
```

 Checks the performance of a UDP service.
 Return value: *Float*: 0.000000 - the service is down; *seconds* - the number of seconds spent waiting for response from the service.

Parameters:

- **service** - possible values: *ntp* (see [details](#));
- **ip** - the IP address or DNS name (by default the host IP/DNS is used);
- **port** - the port number (by default the standard service port number is used).

Example:

```
net.udp.service.perf[ntp] #This item can be used to test the response time from NTP service.
```

Attention:

For SourceIP support in LDAP simple checks (e.g. `net.tcp.service[ldap]`), OpenLDAP version 2.6.1 or above is required.

Timeout processing

Zabbix will not process a simple check longer than the *Timeout* seconds defined in the [item configuration](#) form. For [VMware items](#) items, Zabbix will not process a simple check longer than the *Timeout* seconds defined in the Zabbix [server](#) or [proxy](#) configuration file. For [icmping*](#) items, the timeout and retries values are specified directly in the item key and not influenced by the global *Timeout* parameter. Ensure these values are configured appropriately in the item key.

ICMP pings

Zabbix uses an external utility **fping** to process ICMP pings (**icmpping**, **icmppingloss**, **icmppingsec**).

Installation

fping is not included with Zabbix and needs to be installed separately:

- Various Unix-based platforms have the fping package in their default repositories, but it is not pre-installed. In this case you can use the package manager to install fping.
- Zabbix provides **fping packages** for RHEL and its derivatives. Please note that these packages are provided without official support.
- fping can also be compiled **from source**.

Configuration

Specify fping location in the **FpingLocation** parameter of Zabbix server/proxy configuration file (or **Fping6Location** parameter for using IPv6 addresses).

fping should be executable by the user Zabbix server/proxy run as and this user should have sufficient rights.

See also: **Known issues** for processing simple checks with fping versions below 3.10.

Default values

Defaults, limits and description of values for ICMP check parameters:

| Parameter | Unit | Description | Fping's flag | Defaults set by | | Allowed limits by Zabbix | |
|-----------|-------------|---|--------------|---|---------------|--------------------------|------------|
| | | | | fping | Zabbix | min | max |
| packets | number | number of request packets sent to a target | -C | | 3 | 1 | 10000 |
| interval | millisecond | time to wait between successive packets to an individual target | -p | 1000 | | 20 | unlimited |
| size | bytes | packet size in bytes | -b | 56 or 68 | | 24 | 65507 |
| timeout | millisecond | fping v3.x - timeout to wait after last packet sent, affected by -C flag fping v4.x - individual timeout for each packet | -t | fping v3.x - 500 fping v4.x and newer - inherited from -p flag, but not more than 2000 | | 50 | unlimited |

The defaults may differ slightly depending on the platform and version.

In addition, Zabbix uses fping options **-i interval ms** (do not mix up with the item parameter *interval* mentioned in the table above, which corresponds to fping option **-p**) and **-S source IP address** (or **-I** in older fping versions). These options are auto-detected by running checks with different option combinations. Zabbix tries to detect the minimal value in milliseconds that fping allows to use with **-i** by trying 3 values: 0, 1 and 10. The value that first succeeds is then used for subsequent ICMP checks. This process is done by each **ICMP pinger** process individually.

Auto-detected fping options are invalidated every hour and detected again on the next attempt to perform ICMP check. Set **DebugLevel** ≥ 4 in order to view details of this process in the server or proxy log file.

Zabbix writes IP addresses to be checked by any of the three **icmpping*** keys to a temporary file, which is then passed to fping. If items have different key parameters, only the ones with identical key parameters are written to a single file. All IP addresses written to the single file will be checked by fping in parallel, so Zabbix ICMP pinger process will spend fixed amount of time disregarding the number of IP addresses in the file.

1 VMware monitoring item keys

List of VMware monitoring **item keys** has been moved to **VMware monitoring** section.

6 Log file monitoring

Overview

Zabbix can be used for centralized monitoring and analysis of log files with/without log rotation support.

Notifications can be used to warn users when a log file contains certain strings or string patterns.

To monitor a log file you must have:

- Zabbix agent running on the host
- log monitoring item set up

Attention:

The size limit of a monitored log file depends on **large file support**.

Configuration

Verify agent parameters

Make sure that in the **agent configuration file**:

- 'Hostname' parameter matches the host name in the frontend
- Servers in the 'ServerActive' parameter are specified for the processing of active checks

Item configuration

Configure a log monitoring **item**.

All mandatory input fields are marked with a red asterisk.

Specifically for log monitoring items you enter:

Type **Select Zabbix agent (active)** here.

| | |
|--------------------------|---|
| Key | <p>Use one of the following item keys:</p> <p>log[] or logrt[]:</p> <p>These two item keys allow to monitor logs and filter log entries by the content regexp, if present. For example: <code>log[/var/log/syslog,error]</code>. Make sure that the file has read permissions for the 'zabbix' user otherwise the item status will be set to 'unsupported'.</p> <p>log.count[] or logrt.count[]:</p> <p>These two item keys allow to return the number of matching lines only. See supported Zabbix agent item key section for details on using these item keys and their parameters.</p> |
| Type of information | <p>Prefilled automatically:</p> <p>For <code>log[]</code> or <code>logrt[]</code> items - Log;</p> <p>For <code>log.count[]</code> or <code>logrt.count[]</code> items - Numeric (unsigned).</p> <p>If optionally using the output parameter, you may manually select the appropriate type of information other than Log.</p> <p>Note that choosing a non-Log type of information will lead to the loss of local timestamp.</p> |
| Update interval (in sec) | <p>The parameter defines how often Zabbix agent will check for any changes in the log file. Setting it to 1 second will make sure that you get new records as soon as possible.</p> |
| Log time format | <p>In this field you may optionally specify the pattern for parsing the log line timestamp. Supported placeholders:</p> <ul style="list-style-type: none"> * y: Year (1970-2038) * M: Month (01-12) * d: Day (01-31) * h: Hour (00-23) * m: Minute (00-59) * s: Second (00-59) <p>If left blank, the timestamp will be set to 0 in Unix time, representing January 1, 1970. For example, consider the following line from the Zabbix agent log file:</p> <p>" 23480:20100328:154718.045 Zabbix agent started. Zabbix 1.8.2 (revision 11211)."</p> <p>It begins with six character positions for PID, followed by date, time, and the rest of the message. The log time format for this line would be "pppppp:yyyyMMdd:hhmmss".</p> <p>Note that "p" and ":" characters are placeholders and can be any character except "yMdhms".</p> |

Important notes

- The server and agent keep the trace of a monitored log's size and last modification time (for `logrt`) in two counters. Additionally:
 - The agent also internally uses inode numbers (on UNIX/GNU/Linux), file indexes (on Microsoft Windows) and MD5 sums of the first 512 log file bytes for improving decisions when logfiles get truncated and rotated.
 - On UNIX/GNU/Linux systems it is assumed that the file systems where log files are stored report inode numbers, which can be used to track files.
 - On Microsoft Windows Zabbix agent determines the file system type the log files reside on and uses:
 - * On NTFS file systems 64-bit file indexes.
 - * On ReFS file systems (only from Microsoft Windows Server 2012) 128-bit file IDs.
 - * On file systems where file indexes change (e.g. FAT32, exFAT) a fall-back algorithm is used to take a sensible approach in uncertain conditions when log file rotation results in multiple log files with the same last modification time.
 - The inode numbers, file indexes and MD5 sums are internally collected by Zabbix agent. They are not transmitted to Zabbix server and are lost when Zabbix agent is stopped.
 - Do not modify the last modification time of log files with 'touch' utility, do not copy a log file with later restoration of the original name (this will change the file inode number). In both cases the file will be counted as different and will be analyzed from the start, which may result in duplicated alerts.
 - If there are several matching log files for `logrt []` item and Zabbix agent is following the most recent of them and this most recent log file is deleted, a warning message "there are no files matching "<regexp mask>" in "<directory>" is logged. Zabbix agent ignores log files with modification time less than the most recent modification time seen by the agent for the `logrt []` item being checked.
- The agent starts reading the log file from the point it stopped the previous time.
- The number of bytes already analyzed (the size counter) and last modification time (the time counter) are stored in the Zabbix database and are sent to the agent to make sure the agent starts reading the log file from this point in cases when the agent is just started or has received items which were previously disabled or not supported. However, if the agent has received a non-zero size counter from server, but the `logrt[]` or `logrt.count[]` item is unable to find matching files, the size counter is reset to 0 to analyze from the start if the files appear later.
- Whenever the log file becomes smaller than the log size counter known by the agent, the counter is reset to zero and the

agent starts reading the log file from the beginning taking the time counter into account.

- If there are several matching files with the same last modification time in the directory, then the agent tries to correctly analyze all log files with the same modification time and avoid skipping data or analyzing the same data twice, although it cannot be guaranteed in all situations. The agent does not assume any particular log file rotation scheme nor determines one. When presented multiple log files with the same last modification time, the agent will process them in a lexicographically descending order. Thus, for some rotation schemes the log files will be analyzed and reported in their original order. For other rotation schemes the original log file order will not be honored, which can lead to reporting matched log file records in altered order (the problem does not happen if log files have different last modification times).
- Zabbix agent processes new records of a log file once per *Update interval* seconds.
- Zabbix agent does not send more than **maxlines** of a log file per second. The limit prevents overloading of network and CPU resources and overrides the default value provided by **MaxLinesPerSecond** parameter in the **agent configuration file**.
- To find the required string Zabbix will process 10 times more new lines than set in **MaxLinesPerSecond**. Thus, for example, if a `log[]` or `logrt[]` item has *Update interval* of 1 second, by default the agent will analyze no more than 200 log file records and will send no more than 20 matching records to Zabbix server in one check. By increasing **MaxLinesPerSecond** in the agent configuration file or setting **maxlines** parameter in the item key, the limit can be increased up to 10000 analyzed log file records and 1000 matching records sent to Zabbix server in one check. If the *Update interval* is set to 2 seconds the limits for one check would be set 2 times higher than with *Update interval* of 1 second.
- Additionally, log and log.count values are always limited to 50% of the agent send buffer size, even if there are no non-log values in it. So for the **maxlines** values to be sent in one connection (and not in several connections), the agent **BufferSize** parameter must be at least **maxlines** x 2. Zabbix agent can upload data during log gathering and thus free the buffer, whereas Zabbix agent 2 will stop log gathering until the data is uploaded and the buffer is freed, which is performed asynchronously.
- In the absence of log items all agent buffer size is used for non-log values. When log values come in they replace the older non-log values as needed, up to the designated 50%.
- For log file records longer than 256kB, only the first 256kB are matched against the regular expression and the rest of the record is ignored. However, if Zabbix agent is stopped while it is dealing with a long record the agent internal state is lost and the long record may be analyzed again and differently after the agent is started again.
- Special note for "\" path separators: if file_format is "file.log", then there should not be a "file" directory, since it is not possible to unambiguously define whether "." is escaped or is the first symbol of the file name.
- Regular expressions for `logrt` are supported in filename only, directory regular expression matching is not supported.
- On UNIX platforms a `logrt[]` item becomes NOTSUPPORTED if a directory where the log files are expected to be found does not exist.
- On Microsoft Windows, if a directory does not exist the item will not become NOTSUPPORTED (for example, if directory is misspelled in item key).
- An absence of log files for `logrt[]` item does not make it NOTSUPPORTED. Errors of reading log files for `logrt[]` item are logged as warnings into Zabbix agent log file but do not make the item NOTSUPPORTED.
- Zabbix agent log file can be helpful to find out why a `log[]` or `logrt[]` item became NOTSUPPORTED. Zabbix can monitor its agent log file, except when at `DebugLevel=4` or `DebugLevel=5`.
- Searching for a question mark using a regular expression, e.g. `\?` may result in false positives if the text file contains NUL symbols, as those are replaced with "?" by Zabbix to continue processing the line until the newline character.

Extracting matching part of regular expression

Sometimes we may want to extract only the interesting value from a target file instead of returning the whole line when a regular expression match is found.

Log items have the ability to extract desired values from matched lines. This is accomplished by the additional **output** parameter in `log` and `logrt` items.

Using the 'output' parameter allows to indicate the "capturing group" of the match that we may be interested in.

So, for example

```
log[/path/to/the/file,"large result buffer allocation.*Entries: ([0-9]+)",,,\1]
```

should allow returning the entry count as found in the content of:

```
Fr Feb 07 2014 11:07:36.6690 */ Thread Id 1400 (GLEWF) large result
buffer allocation - /Length: 437136/Entries: 5948/Client Ver: >=10/RPC
ID: 41726453/User: AUser/Form: CFG:ServiceLevelAgreement
```

Only the number will be returned because `\1` refers to the first and only capturing group: **([0-9]+)**.

And, with the ability to extract and return a number, the value can be used to define triggers.

Using `maxdelay` parameter

The 'maxdelay' parameter in log items allows ignoring some older lines from log files in order to get the most recent lines analyzed within the 'maxdelay' seconds.

Warning:

Specifying 'maxdelay' > 0 may lead to **ignoring important log file records and missed alerts**. Use it carefully at your own risk only when necessary.

By default items for log monitoring follow all new lines appearing in the log files. However, there are applications which in some situations start writing an enormous number of messages in their log files. For example, if a database or a DNS server is unavailable, such applications flood log files with thousands of nearly identical error messages until normal operation is restored. By default, all those messages will be dutifully analyzed and matching lines sent to server as configured in log and logrt items.

Built-in protection against overload consists of a configurable 'maxlines' parameter (protects server from too many incoming matching log lines) and a 10*'maxlines' limit (protects host CPU and I/O from overloading by agent in one check). Still, there are 2 problems with the built-in protection. First, a large number of potentially not-so-informative messages are reported to server and consume space in the database. Second, due to the limited number of lines analyzed per second the agent may lag behind the newest log records for hours. Quite likely, you might prefer to be sooner informed about the current situation in the log files instead of crawling through old records for hours.

The solution to both problems is using the 'maxdelay' parameter. If 'maxdelay' > 0 is specified, during each check the number of processed bytes, the number of remaining bytes and processing time is measured. From these numbers the agent calculates an estimated delay - how many seconds it would take to analyze all remaining records in a log file.

If the delay does not exceed 'maxdelay' then the agent proceeds with analyzing the log file as usual.

If the delay is greater than 'maxdelay' then the agent **ignores a chunk of a log file by "jumping" over it** to a new estimated position so that the remaining lines could be analyzed within 'maxdelay' seconds.

Note that agent does not even read ignored lines into buffer, but calculates an approximate position to jump to in a file.

The fact of skipping log file lines is logged in the agent log file like this:

```
14287:20160602:174344.206 item:"logrt[/home/zabbix32/test[0-9].log",ERROR,,1000,,120.0]"
logfile:"/home/zabbix32/test1.log" skipping 679858 bytes
(from byte 75653115 to byte 76332973) to meet maxdelay
```

The "to byte" number is approximate because after the "jump" the agent adjusts the position in the file to the beginning of a log line which may be further in the file or earlier.

Depending on how the speed of growing compares with the speed of analyzing the log file you may see no "jumps", rare or often "jumps", large or small "jumps", or even a small "jump" in every check. Fluctuations in the system load and network latency also affect the calculation of delay and hence, "jumping" ahead to keep up with the "maxdelay" parameter.

Setting 'maxdelay' < 'update interval' is not recommended (it may result in frequent small "jumps").

Notes on handling 'copytruncate' log file rotation

logrt with the copytruncate option assumes that different log files have different records (at least their timestamps are different), therefore MD5 sums of initial blocks (up to the first 512 bytes) will be different. Two files with the same MD5 sums of initial blocks means that one of them is the original, another - a copy.

logrt with the copytruncate option makes effort to correctly process log file copies without reporting duplicates. However, things like producing multiple log file copies with the same timestamp, log file rotation more often than logrt[] item update interval, frequent restarting of agent are not recommended. The agent tries to handle all these situations reasonably well, but good results cannot be guaranteed in all circumstances.

Notes on persistent files for log*[] items

Purpose of persistent files

When Zabbix agent is started it receives a list of active checks from Zabbix server or proxy. For log*[] metrics it receives the processed log size and the modification time for finding where to start log file monitoring from. Depending on the actual log file size and modification time reported by file system the agent decides either to continue log file monitoring from the processed log size or re-analyze the log file from the beginning.

A running agent maintains a larger set of attributes for tracking all monitored log files between checks. This in-memory state is lost when the agent is stopped.

The new optional parameter **persistent_dir** specifies a directory for storing this state of log[], log.count[], logrt[] or logrt.count[] item in a file. The state of log item is restored from the persistent file after the Zabbix agent is restarted.

The primary use-case is monitoring of log file located on a mirrored file system. Until some moment in time the log file is written to both mirrors. Then mirrors are split. On the active copy the log file is still growing, getting new records. Zabbix agent analyzes it and sends processed logs size and modification time to server. On the passive copy the log file stays the same, well behind the active copy. Later the operating system and Zabbix agent are rebooted from the passive copy. The processed log size and

modification time the Zabbix agent receives from server may not be valid for situation on the passive copy. To continue log file monitoring from the place the agent left off at the moment of file system mirror split the agent restores its state from the persistent file.

Agent operation with persistent file

On startup Zabbix agent knows nothing about persistent files. Only after receiving a list of active checks from Zabbix server (proxy) the agent sees that some log items should be backed by persistent files under specified directories.

During agent operation the persistent files are opened for writing (with `fopen(filename, "w")`) and overwritten with the latest data. The chance of losing persistent file data if the overwriting and file system mirror split happen at the same time is very small, no special handling for it. Writing into persistent file is NOT followed by enforced synchronization to storage media (`fsync()` is not called).

Overwriting with the latest data is done after successful reporting of matching log file record or metadata (processed log size and modification time) to Zabbix server. That may happen as often as every item check if log file keeps changing.

No special actions during agent shutdown.

After receiving a list of active checks the agent marks obsolete persistent files for removal. A persistent file becomes obsolete if: 1) the corresponding log item is no longer monitored, 2) a log item is reconfigured with a different **persistent_dir** location than before.

Removing is done with delay 24 hours because log files in NOTSUPPORTED state are not included in the list of active checks but they may become SUPPORTED later and their persistent files will be useful.

If the agent is stopped before 24 hours expire, then the obsolete files will not be deleted as Zabbix agent is not getting info about their location from Zabbix server anymore.

Warning:

Reconfiguring a log item's **persistent_dir** back to the old **persistent_dir** location while the agent is stopped, without deleting the old persistent file by user - will cause restoring the agent state from the old persistent file resulting in missed messages or false alerts.

Naming and location of persistent files

Zabbix agent distinguishes active checks by their keys. For example, `logrt[/home/zabbix/test.log]` and `logrt[/home/zabbix/test.log,]` are different items. Modifying the item `logrt[/home/zabbix/test.log,,10]` in frontend to `logrt[/home/zabbix/test.log,,20]` will result in deleting the item `logrt[/home/zabbix/test.log,,10]` from the agent's list of active checks and creating `logrt[/home/zabbix/test.log,,20]` item (some attributes are carried across modification in frontend/server, not in agent).

The file name is composed of MD5 sum of item key with item key length appended to reduce possibility of collisions. For example, the state of `logrt[/home/zabbix50/test.log,,,,,]/home/zabbix50/agent_private` item will be kept in persistent file `c963ade4008054813bbc0a650bb8e09266`.

Multiple log items can use the same value of **persistent_dir**.

persistent_dir is specified by taking into account specific file system layouts, mount points and mount options and storage mirroring configuration - the persistent file should be on the same mirrored filesystem as the monitored log file.

If **persistent_dir** directory cannot be created or does not exist, or access rights for Zabbix agent does not allow to create/write/read/delete files the log item becomes NOTSUPPORTED.

If access rights to persistent storage files are removed during agent operation or other errors occur (e.g. disk full) then errors are logged into the agent log file but the log item does not become NOTSUPPORTED.

Load on I/O

Item's persistent file is updated after successful sending of every batch of data (containing item's data) to server. For example, default 'BufferSize' is 100. If a log item has found 70 matching records then the first 50 records will be sent in one batch, persistent file will be updated, then remaining 20 records will be sent (maybe with some delay when more data is accumulated) in the 2nd batch, and the persistent file will be updated again.

Actions if communication fails between agent and server

Each matching line from `log[]` and `logrt[]` item and a result of each `log.count[]` and `logrt.count[]` item check requires a free slot in the designated 50% area in the agent send buffer. The buffer elements are regularly sent to server (or proxy) and the buffer slots are free again.

While there are free slots in the designated log area in the agent send buffer and communication fails between agent and server (or proxy) the log monitoring results are accumulated in the send buffer. This helps to mitigate short communication failures.

During longer communication failures all log slots get occupied and the following actions are taken:

- `log[]` and `logrt[]` item checks are stopped. When communication is restored and free slots in the buffer are available the checks are resumed from the previous position. No matching lines are lost, they are just reported later.
- `log.count[]` and `logrt.count[]` checks are stopped if `maxdelay = 0` (default). Behavior is similar to `log[]` and `logrt[]` items as described above. Note that this can affect `log.count[]` and `logrt.count[]` results: for example, one check counts 100 matching lines in a log file, but as there are no free slots in the buffer the check is stopped. When communication is restored the agent counts the same 100 matching lines and also 70 new matching lines. The agent now sends `count = 170` as if they were found in one check.
- `log.count[]` and `logrt.count[]` checks with `maxdelay > 0`: if there was no "jump" during the check, then behavior is similar to described above. If a "jump" over log file lines took place then the position after "jump" is kept and the counted result is discarded. So, the agent tries to keep up with a growing log file even in case of communication failure.

Handling of regular expression compilation and runtime errors

If a regular expression used in `log[]`, `logrt[]`, `log.count[]` or `logrt.count[]` item cannot be compiled by PCRE or PCRE2 library then the item goes into `NOTSUPPORTED` state with an error message. To continue monitoring the log item, the regular expression should be fixed.

If the regular expression compiles successfully, but fails at runtime (on some or on all log records), then the log item remains supported and monitoring continues. The runtime error is logged in the Zabbix agent log file (without the log file record).

The logging rate is limited to one runtime error per check to allow Zabbix agent to monitor its own log file. For example, if 10 records are analyzed and 3 records fail with a `regex` runtime error, one record is produced in the agent log.

Exception: if `MaxLinesPerSecond=1` and `update interval=1` (only 1 record is allowed to analyze per check) then `regex` runtime errors are not logged.

`zabbix_agentd` logs the item key in case of a runtime error, `zabbix_agent2` logs the item ID to help identify which log item has runtime errors. It is recommended to redesign the regular expression in case of runtime errors.

7 Calculated items

Overview

A calculated item allows to create a calculation based on the values of some existing items. For example, you may want to calculate the hourly average of some item value or to calculate the total value for a group of items. That is what a calculated item is for.

Calculations may use both:

- single values of individual items
- a complex filter to select multiple items for aggregation (see [aggregate calculations](#) for details)

Calculated items are a way of creating virtual data sources. All calculations are done by Zabbix server only. The values are periodically calculated based on the arithmetical expression used.

The resulting data is stored in the Zabbix database as for any other item; both history and trend values are stored and graphs can be generated.

Note:

If the calculation result is a float value it will be trimmed to an integer if the calculated item type of information is *Numeric (unsigned)*.

Also, if there is no recent data in the cache and there is no defined querying period in the function, Zabbix will by default go as far back in the past as one week to query the database for historical values.

Calculated items share their syntax with trigger [expressions](#). Comparison to strings is allowed in calculated items. Calculated items may be referenced by macros or other entities same as any other item type.

To use calculated items, choose the item type **Calculated**.

Configurable fields

The **key** is a unique item identifier (per host). You can create any key name using supported symbols.

The calculation definition should be entered in the **Formula** field. There is no connection between the formula and the key. The key parameters are not used in the formula in any way.

The syntax of a simple formula is:

```
function(/host/key,<parameter1>,<parameter2>,...)
```

where:

| | |
|---------------------|---|
| <i>function</i> | One of the supported functions : last, min, max, avg, count, etc |
| <i>host</i> | Host of the item that is used for calculation. The current host can be omitted (i.e. as in <code>function(//key,parameter,...)</code>). |
| <i>key</i> | Key of the item that is used for calculation. |
| <i>parameter(s)</i> | Parameters of the function, if required. Time suffixes and memory size suffixes are supported. |

Attention:

User macros in the formula will be expanded if used to reference a function parameter, item filter parameter, or a constant. User macros will NOT be expanded if referencing a function, host name, item key, item key parameter or operator.

A more complex formula may use a combination of functions, operators and brackets. You can use all functions and **operators** supported in trigger expressions. The logic and operator precedence are exactly the same.

Unlike trigger expressions, Zabbix processes calculated items according to the item update interval, not upon receiving a new value.

All items that are referenced by history functions in the calculated item formula must exist and be collecting data. Also, if you change the item key of a referenced item, you have to manually update any formulas using that key.

A calculated item may become unsupported in several cases:

- referenced item(s)
 - is not found
 - is disabled
 - belongs to a disabled host
 - is not supported (except with `nodata()` function and **operators** with unknown values)
- no data to calculate a function
- division by zero
- incorrect syntax used

Usage examples

Example 1

Calculating percentage of free disk space on '/'.

Use of function **last**:

```
100*last(//vfs.fs.size[/,free])/last(//vfs.fs.size[/,total])
```

Zabbix will take the latest values for free and total disk spaces and calculate percentage according to the given formula.

Example 2

Calculating a 10-minute average of the number of values processed by Zabbix.

Use of function **avg**:

```
avg(/Zabbix Server/zabbix[wcache,values],10m)
```

Note that extensive use of calculated items with long time periods may affect performance of Zabbix server.

Example 3

Calculating total bandwidth on eth0.

Sum of two functions:

```
last(//net.if.in[eth0,bytes])+last(//net.if.out[eth0,bytes])
```

Example 4

Calculating percentage of incoming traffic.

More complex expression:

```
100*last(//net.if.in[eth0,bytes])/(last(//net.if.in[eth0,bytes])+last(//net.if.out[eth0,bytes]))
```

See also: **Examples of aggregate calculations**

1 Aggregate calculations

Overview

Aggregate calculations are a **calculated item** type allowing to collect information from several items by Zabbix server and then calculate an aggregate, depending on the aggregate function used.

Aggregate calculations do not require any agent running on the host being monitored.

Syntax

To retrieve aggregates use one of the supported **aggregate functions**: avg, max, min, sum, etc. Then add the **foreach** function as the only parameter and its item filter to select the required items:

```
aggregate_function(function_foreach(/host/key?[group="host group"],timeperiod))
```

A **foreach** function (e.g. *avg_foreach*, *count_foreach*, etc.) returns one aggregate value for each selected item. Items are selected by using the item filter (/host/key?[group="host group"]), from item history. For more details, see **foreach functions**.

If some of the items have no data for the requested period, they are ignored in the calculation. If no items have data, the function will return an error.

Alternatively you may list several items as parameters for aggregation:

```
aggregate_function(function(/host/key,parameter),function(/host2/key2,parameter),...)
```

Note that **function** here must be a history/trend function.

Note:

If the aggregate results in a float value it will be trimmed to an integer if the aggregated item type of information is *Numeric (unsigned)*.

User macros and low-level discovery macros are supported in:

- item key parameters
- function parameters
- filter conditions (host group name and tag name)
- expression constants

An aggregate calculation may become unsupported if:

- none of the referenced items is found (which may happen if the item key is incorrect, none of the items exists or all included groups are incorrect)
- no data to calculate a function

Usage examples

Examples of keys for aggregate calculations.

Example 1

Total disk space of host group 'MySQL Servers'.

```
sum(last_foreach(/*/vfs.fs.size[/,total]?[group="MySQL Servers"]))
```

Example 2

Sum of latest values of all items matching net.if.in[*] on the host.

```
sum(last_foreach(/host/net.if.in[*]))
```

Example 3

Average processor load of host group 'MySQL Servers'.

```
avg(last_foreach(/*/system.cpu.load[,avg1]?[group="MySQL Servers"]))
```

Example 4

5-minute average of the number of queries per second for host group 'MySQL Servers'.

```
avg(avg_foreach(/*/mysql.qps?[group="MySQL Servers"],5m))
```

Example 5

Average CPU load on all hosts in multiple host groups that have the specific tags.

`avg(last_foreach(/*/system.cpu.load?[group="Servers A" or group="Servers B" or group="Servers C"]) and (ta`

Example 6

Calculation used on the latest item value sums of a whole host group.

`sum(last_foreach(/*/net.if.out[eth0,bytes]?[group="video"])) / sum(last_foreach(/*/nginx_stat.sh[active]?[`

Example 7

The total number of unsupported items in host group 'Zabbix servers'.

`sum(last_foreach(/*/zabbix[host,,items_unsupported]?[group="Zabbix servers"]))`

Examples of correct/incorrect syntax

Expressions (including function calls) cannot be used as history, trend, or foreach **function** parameters. However, those functions themselves can be used in other (non-historical) function parameters.

| Expression | Example |
|------------|--|
| Valid | <code>avg(last(/host/key1),last(/host/key2)*10,last(/host/key1)*100) max(avg(avg_foreach(/*/system.cpu.load?[group="Servers A"],5m)),avg(avg_foreach(/*/system.cpu.load?[group="Servers B"],5m)),avg(avg_foreach(/*/system.cpu.load?[group="Servers C"],5m)))</code> |
| Invalid | <code>sum(/host/key,10+2) sum(/host/key, avg(10,2)) sum(/host/key,last(/host/key2))</code> |

Note that in an expression like:

`sum(sum_foreach(/resptime[*],5m))/sum(count_foreach(/resptime[*],5m))`

it cannot be guaranteed that both parts of the equation will always have the same set of values. While one part of the expression is evaluated, a new value for the requested period may arrive and then the other part of the expression will have a different set of values.

8 Internal checks

Overview

Internal checks allow to monitor the internal processes of Zabbix. In other words, you can monitor what goes on with Zabbix server or Zabbix proxy.

Internal checks are calculated:

- on Zabbix server - if the host is monitored by server
- on Zabbix proxy - if the host is monitored by proxy

Internal checks are processed by server or proxy regardless of the host maintenance status.

To use this item, choose the **Zabbix internal** item type.

Note:

Internal checks are processed by Zabbix pollers.

Performance

Using some internal items may negatively affect performance. These items are:

- `zabbix[host,,items]`
- `zabbix[host,,items_unsupported]`
- `zabbix[hosts]`
- `zabbix[items]`
- `zabbix[items_unsupported]`
- `zabbix[queue,,]`
- `zabbix[requiredperformance]`
- `zabbix[stats,,,queue,,]`
- `zabbix[triggers]`

The **System information** and **Queue** frontend sections are also affected.

Supported checks

The item keys are listed without customizable parameters and additional information. Click on the item key to see the full details.

| Item key | Description |
|--|--|
| zabbix[boottime] | The startup time of Zabbix server or Zabbix proxy process in seconds. |
| zabbix[cluster,discovery,nodes] | Discovers the high availability cluster nodes. |
| zabbix[connector_queue] | The count of values enqueued in the connector queue. |
| zabbix[discovery_queue] | The count of network checks enqueued in the discovery queue. |
| zabbix[host,,items] | The number of enabled items (supported and not supported) on the host. |
| zabbix[host,,items_unsupported] | The number of enabled unsupported items on the host. |
| zabbix[host,,maintenance] | The current maintenance status of the host. |
| zabbix[host,active_agent,availability] | The availability of active agent checks on the host. |
| zabbix[host,discovery,interfaces] | Details of all configured interfaces of the host in Zabbix frontend. |
| zabbix[host,,available] | The availability of the main interface of a particular type of checks on the host. |
| zabbix[hosts] | The number of monitored hosts. |
| zabbix[items] | The number of enabled items (supported and not supported). |
| zabbix[items_unsupported] | The number of unsupported items. |
| zabbix[java,,] | The information about Zabbix Java gateway. |
| zabbix[lld_queue] | The count of values enqueued in the low-level discovery processing queue. |
| zabbix[preprocessing] | Statistics of the values received by the preprocessing manager. |
| zabbix[preprocessing_queue] | The count of values enqueued in the preprocessing queue. |
| zabbix[process,,] | The percentage of time a particular Zabbix process or a group of processes (identified by <type> and <mode>) spent in <state>. |
| zabbix[proxy,,] | The information about Zabbix proxy. |
| zabbix[proxy,discovery] | The list of Zabbix proxies. |
| zabbix[proxy group,,available] | The number of online proxies in a proxy group. |
| zabbix[proxy group,,pavailable] | The percentage of online proxies in a proxy group. |
| zabbix[proxy group,,proxies] | The list of Zabbix proxies in a proxy group. |
| zabbix[proxy group,,state] | The state of a proxy group. |
| zabbix[proxy group,discovery] | Returns a list of proxy groups with configuration data and real-time data. |
| zabbix[proxy_buffer,buffer,] | Returns the proxy memory buffer usage statistics. |
| zabbix[proxy_buffer,state,changes] | Returns the number of state changes between disk/memory buffer modes since start. |
| zabbix[proxy_buffer,state,current] | Returns the current working state where the new data are being stored. |
| zabbix[proxy_history] | The number of values in the proxy history table waiting to be sent to the server. |
| zabbix[queue,,] | The number of monitored items in the queue which are delayed at least by <from> seconds, but less than <to> seconds. |
| zabbix[rcache,,] | The availability statistics of the Zabbix configuration cache. |
| zabbix[requiredperformance] | The required performance of Zabbix server or Zabbix proxy, in new values per second expected. |
| zabbix[stats,,] | The internal metrics of a remote Zabbix server or proxy. |
| zabbix[stats,,queue,,] | The internal queue metrics of a remote Zabbix server or proxy. |
| zabbix[tcache,,] | The effectiveness statistics of the Zabbix trend function cache. |
| zabbix[triggers] | The number of enabled triggers in Zabbix database, with all items enabled on enabled hosts. |
| zabbix[uptime] | The uptime of the Zabbix server or proxy process in seconds. |
| zabbix[vcache,buffer,] | The availability statistics of the Zabbix value cache. |
| zabbix[vcache,cache,] | The effectiveness statistics of the Zabbix value cache. |
| zabbix[version] | The version of Zabbix server or proxy. |
| zabbix[vmware,buffer,] | The availability statistics of the Zabbix vmware cache. |
| zabbix[vps,written] | The total number of history values written to database. |
| zabbix[wcache,,] | The statistics and availability of the Zabbix write cache. |

Item key details

- Parameters without angle brackets are mandatory and must be used as *is* (for example, "host" and "available" in `zabbix[host,<type>,available]`).
- Parameters with angle brackets < > must be replaced with a valid value. If a parameter has a default value, it can be omitted.

- Values for items and item parameters labeled "not supported on proxy" can only be retrieved if the host is monitored by server. Conversely, values "not supported on server" can only be retrieved if the host is monitored by proxy.

zabbix[boottime]

 The startup time of Zabbix server or Zabbix proxy process in seconds.
 Return value: *Integer*.

zabbix[cluster,discovery,nodes]

 Discovers the **high availability cluster** nodes.
 Return value: *JSON object*.

Comments:

- This item can be used in low-level discovery.

zabbix[connector_queue]

 The count of values enqueued in the connector queue.
 Return value: *Integer*.

zabbix[discovery_queue]

 The count of network checks enqueued in the discovery queue.
 Return value: *Integer*.

zabbix[host,,items]

 The number of enabled items (supported and not supported) on the host.
 Return value: *Integer*.

zabbix[host,,items_unsupported]

 The number of enabled unsupported items on the host.
 Return value: *Integer*.

zabbix[host,,maintenance]

 The current maintenance status of the host.
 Return values: 0 - normal state; 1 - maintenance with data collection; 2 - maintenance without data collection.

Comments:

- This item is always processed by Zabbix server regardless of the host location (on server or proxy). The proxy will not receive this item with configuration data.
- The second parameter must be empty and is reserved for future use.

zabbix[host,active_agent,available]

 The availability of active agent checks on the host.
 Return values: 0 - unknown; 1 - available; 2 - not available.

zabbix[host,discovery,interfaces]

 The details of all configured interfaces of the host in Zabbix frontend.
 Return value: *JSON object*.

Comments:

- This item can be used in **low-level discovery**.
- This item is not supported on Zabbix proxy.

zabbix[host,<type>,available]

 The availability of the main interface of a particular type of checks on the host.
 Return values: 0 - not available; 1 - available; 2 - unknown.

Parameters:

- **type** - *agent, snmp, ipmi, or jmx*.

Comments:

- The item value is calculated according to the configuration parameters regarding host **unreachability/unavailability**.

zabbix**hosts**

 The number of monitored hosts.
 Return value: *Integer*.

zabbix**items**

 The number of enabled items (supported and not supported).
 Return value: *Integer*.

zabbix[items_unsupported]

 The number of unsupported items.
 Return value: *Integer*.

zabbix[java,,<param>]

 The information about Zabbix Java gateway.
 Return values: 1 - if <param> is *ping*; *Java gateway version* - if <param> is *version* (for example: "7.2.0").

Parameters:

- **param** - *ping* or *version*.

Comments:

- This item can be used to check Java gateway availability using the `nodata()` trigger function.
- The second parameter must be empty and is reserved for future use.

`zabbix[lld_queue]`

 The count of values enqueued in the low-level discovery processing queue.
 Return value: *Integer*.

Comments:

- This item can be used to monitor the low-level discovery processing queue length.

`zabbix

```
preprocessing
````

 Statistics of the values received by the preprocessing manager:
 - *queued* - the number and size of queued values that require preprocessing (counter)
 - *direct* - the number and size of queued values that do not require preprocessing (counter)
 - *queue* - the count of values enqueued in the preprocessing queue (same as `zabbix[preprocessing_queue]`)
 Return value: *JSON*.

This item is supported since Zabbix 7.2.6.

Example of return values:

```
{
  "data": {
    "queued": {
      "count": 106,
      "size": 58620
    },
    "direct": {
      "count": 395,
      "size": 33843
    },
    "queue": 0
  }
}
```

`zabbix[preprocessing_queue]`

 The count of values enqueued in the preprocessing queue.
 Return value: *Integer*.

Comments:

- This item can be used to monitor the preprocessing queue length.

`zabbix[process,<type>,<mode>,<state>]`

 The percentage of time a particular Zabbix process or a group of processes (identified by <type> and <mode>) spent in <state>. It is calculated for the last minute only.
 Return value: *Float*.

Parameters:

- **type** - for **server processes**: *agent poller, alert manager, alert syncer, alerter, availability manager, browser poller, configuration syncer, configuration syncer worker, connector manager, connector worker, discovery manager, discovery worker, escalator, ha manager, history poller, history syncer, housekeeper, http agent poller, http poller, icmp pinger, internal poller, ipmi manager, ipmi poller, java poller, lld manager, lld worker, odbc poller, poller, preprocessing manager, preprocessing worker, proxy group manager, proxy poller, self-monitoring, service manager, snmp poller, snmp trapper, task manager, timer, trapper, trigger housekeeper, unreachable poller, vmware collector*;
 for **proxy processes**: *agent poller, availability manager, browser poller, configuration syncer, data sender, discovery manager, discovery worker, history syncer, housekeeper, http agent poller, http poller, icmp pinger, internal poller, ipmi manager, ipmi poller, java poller, odbc poller, poller, preprocessing manager, preprocessing worker, self-monitoring, snmp poller, snmp trapper, task manager, trapper, unreachable poller, vmware collector*;
- **mode** - *avg* - average value for all processes of a given type (default);
 count - returns number of forks for a given process type, <state> should not be specified;
 max - maximum value;
 min - minimum value;
 <process number> -

process number (between 1 and the number of pre-forked instances; for example, if 4 trappers are running, the value is between 1 and 4);

- **state** - *busy* - process is in busy state, for example, the processing request (default);
idle - process is in idle state doing nothing.

Comments:

- If `<mode>` is a Zabbix process number that is not running (for example, with 5 pollers running the `<mode>` is specified to be 6), such an item will turn unsupported.
- Minimum and maximum refers to the usage percentage for a single process. So if in a group of 3 pollers usage percentages per process were 2, 18 and 66, min would return 2 and max would return 66.
- Processes report what they are doing in shared memory and the self-monitoring process summarizes that data each second. State changes (busy/idle) are registered upon change - thus a process that becomes busy registers as such and doesn't change or update the state until it becomes idle. This ensures that even fully hung processes will be correctly registered as 100% busy.
- Currently, "busy" means "not sleeping", but in the future additional states might be introduced - waiting for locks, performing database queries, etc. Note that asynchronous pollers are considered busy if they have reached the limit set by the `MaxConcurrentChecksPerPoller` [server/proxy](#) configuration parameter.
- On Linux and most other systems, resolution is 1/100 of a second.

Examples:

```
zabbix[process,poller,avg,busy] #the average time of poller processes spent doing something during the last second
zabbix[process,"icmp pinger",max,busy] #the maximum time spent doing something by any ICMP pinger process
zabbix[process,"history syncer",2,busy] #the time spent doing something by history syncer number 2 during the last second
zabbix[process,trapper,count] #the amount of currently running trapper processes
```

```
zabbix[proxy,<name>,<param>]
```

 The information about Zabbix proxy.
 Return value: *Integer*.

Parameters:

- **name** - the proxy name;
- **param** - *lastaccess* - the timestamp of the last heartbeat message received from proxy;
delay - how long the collected values are unsent; calculated as "proxy delay" + ("current server time" - "proxy lastaccess"), where "proxy delay" is the difference between the current proxy time and the timestamp of the oldest unsent value on proxy.

Comments:

- This item is always processed by Zabbix server regardless of host location (on server or proxy).
- The `fuzzytime()` function can be used to check the availability of proxy.

Example:

```
zabbix[proxy,"Germany",lastaccess] #the timestamp of the last heartbeat message received from "Germany" proxy
zabbix[proxy,discovery]
```

 The list of Zabbix proxies with name, mode, encryption, compression, version, last seen, host count, item count, required values per second (vps), version status (current/outdated/unsupported), timeouts by item type, proxy group name (if proxy belongs to group), state (unknown/offline/online).
 Return value: *JSON object*.

```
zabbix[proxy group,<name>,available]
```

 The number of online proxies in a proxy group.
 Return value: *Integer*.

Parameters:

- **name** - the proxy group name.

```
zabbix[proxy group,<name>,pavailable]
```

 The percentage of online proxies in a proxy group.
 Return value: *Float*.

Parameters:

- **name** - the proxy group name.

```
zabbix[proxy group,<name>,proxies]
```

 The list of Zabbix proxies in a proxy group with name, mode, encryption, compression, version, last seen, host count, item count, required values per second (vps), version status (current/outdated/unsupported), timeouts, proxy group name, state (unknown/offline/online).
 Return value: *JSON*.

Parameters:

- **name** - the proxy group name.

zabbix[proxy_group,<name>,state]

 The state of a proxy group.
 Return value: 0 - unknown; 1 - offline; 2 - recovering; 3 - online; 4 - degrading.

Parameters:

- **name** - the proxy group name.

zabbix[proxy_group,discovery]

 Returns a list of proxy groups with configuration data and real-time data. Configuration data include the proxy group name, failover delay, and the minimum number of online proxies required. Real-time data include the proxy group state (see comments for details), the number of online proxies, and the percentage of online proxies.
 Return value: *JSON*.

Comments:

- This item does not return groupless proxies.
- If there is an invalid value for "failover_delay" or "min_online", then a special value -1 is reported to indicate that. Invalid values might occur if macros are used for configuration and the macros cannot be expanded to a valid value.
- The proxy group state is reported as an integer: 0 - unknown; 1 - offline; 2 - recovering; 3 - online; 4 - degrading.

Example of return values:

```
{
  "groups": [
    { "name": "Riga", "failover_delay": 60, "min_online": 1 },
    { "name": "Tokyo", "failover_delay": 60, "min_online": 2 },
    { "name": "Porto Alegre", "failover_delay": 60, "min_online": 3 }
  ],
  "details": {
    "Riga": { "state": 3, "available": 10, "pavailable": 20 },
    "Tokyo": { "state": 3, "available": 10, "pavailable": 20 },
    "Porto Alegre": { "state": 1, "available": 0, "pavailable": 0 }
  }
}
```

zabbix[proxy_buffer,buffer,<mode>]

 The proxy memory buffer usage statistics.
 Return values: *Integer* (for size); *Float* (for percentage).

Parameters:

- **mode**: *total* - the total size of buffer (can be used to check if memory buffer is enabled);
free - the size of free buffer;
pfree - the percentage of free buffer;
used - the size of used buffer;
pused - the percentage of used buffer.

Comments:

- Returns a 'Proxy memory buffer is disabled' error when the memory buffer is disabled;

- This item is not supported on Zabbix server.

zabbix[proxy_buffer,state,changes]

 Returns the number of state changes between disk/memory buffer modes since start.
 Return values: *Integer*; 0 - the memory buffer is disabled.

Comments:

- Frequent state changes indicate that either the memory buffer size or age must be increased.
- If the memory buffer state is monitored infrequently (for example, once a minute) then the buffer might flip its state without it being registered.

zabbix[proxy_buffer,state,current]

 Returns the current working state where the new data are being stored.
 Return values: 0 - disk; 1 - memory.

Comments:

- "0" is also returned when the memory buffer is disabled.

zabbix[proxy_history]

 The number of values in the proxy history table waiting to be sent to the server.
 Return values: *Integer*.

Comments:

- This item is not supported on Zabbix server.

zabbix[queue,<from>,<to>]

 The number of monitored items in the queue which are delayed at least by <from> seconds, but less than <to> seconds.
 Return value: *Integer*.

Parameters:

- **from** - delayed by at least (default is 6 seconds);
- **to** - delayed by at most (default is infinity).

Comments:

- **Time suffixes** (s,m,h,d,w) are supported in the parameters.

Attention:

The Zabbix proxy is not aware of maintenance periods; see [Calculation of queues during maintenance](#) for details.

zabbix[rcache,<cache>,<mode>]

 The availability statistics of the Zabbix configuration cache.
 Return values: *Integer* (for size); *Float* (for percentage).

Parameters:

- **cache** - *buffer*;
- **mode** - *total* - the total size of buffer;
free - the size of free buffer;
pfree - the percentage of free buffer;
used - the size of used buffer;
pused - the percentage of used buffer.

zabbix[requiredperformance]

 The required performance of Zabbix server or Zabbix proxy, in new values per second expected.
 Return value: *Float*.

Comments:

- Approximately correlates with "Required server performance, new values per second" in *Reports* → *System information*.

zabbix[stats,<ip>,<port>]

 The internal metrics of a remote Zabbix server or proxy.
 Return values: *JSON object*.

Parameters:

- **ip** - the IP/DNS/network mask list of servers/proxies to be remotely queried (default is 127.0.0.1);
- **port** - the port of server/proxy to be remotely queried (default is 10051).

Comments:

- The stats request will only be accepted from the addresses listed in the 'StatsAllowedIP' *server/proxy* parameter on the target instance.
- A selected set of internal metrics is returned by this item. For details, see [Remote monitoring of Zabbix stats](#).

zabbix[stats,<ip>,<port>,queue,<from>,<to>]

 The internal queue metrics (see `zabbix[queue,<from>,<to>]`) of a remote Zabbix server or proxy.
 Return values: *JSON object*.

Parameters:

- **ip** - the IP/DNS/network mask list of servers/proxies to be remotely queried (default is 127.0.0.1);
- **port** - the port of server/proxy to be remotely queried (default is 10051);
- **from** - delayed by at least (default is 6 seconds);
- **to** - delayed by at most (default is infinity).

Comments:

- The stats request will only be accepted from the addresses listed in the 'StatsAllowedIP' *server/proxy* parameter on the target instance.
- A selected set of internal metrics is returned by this item. For details, see [Remote monitoring of Zabbix stats](#).

Attention:

The Zabbix proxy is not aware of maintenance periods; see [Calculation of queues during maintenance](#) for details.

zabbix[tcache,<cache>,<parameter>]

 The effectiveness statistics of the Zabbix trend function cache.
 Return values: *Integer* (for size); *Float* (for percentage).

Parameters:

- **cache** - *buffer*;
- **parameter** - *all* - total cache requests (default);
hits - cache hits;
phits - percentage of cache hits;
misses - cache misses;
pmisses - percentage of cache misses;
items - the number of cached items;
requests - the number of cached requests;
pitems - percentage of cached items from cached items + requests. Low percentage most likely means that the cache size can be reduced.

Comments:

- This item is not supported on Zabbix proxy.

zabbixtriggers

 The number of enabled triggers in Zabbix database, with all items enabled on enabled hosts.
 Return value: *Integer*.

Comments:

- This item is not supported on Zabbix proxy.

zabbix[uptime]

 The uptime of the Zabbix server or proxy process in seconds.
 Return value: *Integer*.

zabbix[vcache,buffer,<mode>]

 The availability statistics of the Zabbix value cache.
 Return values: *Integer* (for size); *Float* (for percentage).

Parameters:

- **mode** - *total* - the total size of buffer;
free - the size of free buffer;
pfree - the percentage of free buffer;
used - the size of used buffer;
pused - the percentage of used buffer.

Comments:

- This item is not supported on Zabbix proxy.

zabbix[vcache,cache,<parameter>]

 The effectiveness statistics of the Zabbix value cache.
 Return values: *Integer*. With the *mode* parameter returns: 0 - normal mode; 1 - low memory mode.

Parameters:

- **parameter** - *requests* - the total number of requests;
hits - the number of cache hits (history values taken from the cache);
misses - the number of cache misses (history values taken from the database);
mode - the value cache operating mode.

Comments:

- Once the low-memory mode has been switched on, the value cache will remain in this state for 24 hours, even if the problem that triggered this mode is resolved sooner.
- You may use this key with the *Change per second* preprocessing step in order to get values-per-second statistics.
- This item is not supported on Zabbix proxy.

zabbixversion

 The version of Zabbix server or proxy.
 Return value: *String*. For example: 7.2.0.

zabbix[vmware,buffer,<mode>]

 The availability statistics of the Zabbix vmware cache.
 Return values: *Integer* (for size); *Float* (for percentage).

Parameters:

- **mode** - *total* - the total size of buffer;
free - the size of free buffer;
pfree - the percentage of free buffer;
used - the size of used buffer;
pused - the percentage of used buffer.

zabbix[vps,written]

 The total number of history values written to database.
 Return value: *Integer*.

zabbix[wcache,<cache>,<mode>]

 The statistics and availability of the Zabbix write cache.
 Return values: *Integer* (for number/size); *Float* (for percentage).

Parameters:

- **cache** - *values, history, index, or trend*;
- **mode** - (with *values*) *all* (default) - the total number of values processed by Zabbix server/proxy, except unsupported items (counter);
float - the number of processed float values (counter);
uint - the number of processed unsigned integer values (counter);
str - the number of processed character/string values (counter);
log - the number of processed log values (counter);
text - the number of processed text values (counter);
not supported - the number of times item processing resulted in item becoming unsupported or keeping that state (counter);
(with *history, index, trend* cache) *pfree* (default) - the percentage of free buffer;
total - the total size of buffer;
free - the size of free buffer;
used - the size of used buffer;
pused - the percentage of used buffer.

Comments:

- Specifying <cache> is mandatory. The *trend* cache parameter is not supported with Zabbix proxy.
- The history cache is used to store item values. A low number indicates performance problems on the database side.
- The history index cache is used to index the values stored in the history cache.
- After the history cache is filled and then cleared, the history index cache will still keep some data. This behavior is expected and helps the system run more efficiently by avoiding the extra processing required to constantly resize the memory.
- The trend cache stores the aggregate for the current hour for all items that receive data.
- You may use the zabbix[wcache,values] key with the *Change per second* preprocessing step in order to get values-per-second statistics.

9 SSH checks

Overview

SSH checks are performed as agent-less monitoring. Zabbix agent is not needed for SSH checks.

To perform SSH checks Zabbix server must be initially **configured** with SSH2 support (libssh or libssh2). See also: **Requirements**.

Attention:

Starting with RHEL 8, only libssh is supported. For other distributions, libssh is suggested over libssh2.

Configuration

Passphrase authentication

SSH checks provide two authentication methods - a user/password pair and key-file based.

If you do not intend to use keys, no additional configuration is required, besides linking libssh or libssh2 to Zabbix, if you're building from source.

Key file authentication

To use key based authentication for SSH items, certain changes to the server configuration are required.

Open the Zabbix server configuration file (*zabbix_server.conf*) as root and look for the following line:

```
##### SSHKeyLocation=
```

Uncomment it and set the full path to the folder where the public and private keys will be located:

```
SSHKeyLocation=/home/zabbix/.ssh
```

Save the file and restart Zabbix server afterwards.

The path */home/zabbix* here is the home directory for the *zabbix* user account, and *.ssh* is a directory where by default public and private keys will be generated by an *ssh-keygen* command inside the home directory.

Usually installation packages of Zabbix server from different OS distributions create the *zabbix* user account with a home directory elsewhere, for example, */var/lib/zabbix* (as for system accounts).

Before generating the keys, you could reallocate the home directory to */home/zabbix*, so that it corresponds with the *SSHKeyLocation* Zabbix server configuration parameter mentioned above.

Note:

The following steps can be skipped if *zabbix* account has been added manually according to the [installation section](#). In such a case the home directory for the *zabbix* account is most likely already */home/zabbix*.

To change the home directory of the *zabbix* user account, all working processes which are using it have to be stopped:

```
systemctl stop zabbix-agent
systemctl stop zabbix-server
```

To change the home directory location with an attempt to move it (if it exists) the following command should be executed:

```
usermod -m -d /home/zabbix zabbix
```

It is also possible that a home directory did not exist in the old location, so it should be created at the new location. A safe attempt to do that is:

```
test -d /home/zabbix || mkdir /home/zabbix
```

To be sure that all is secure, additional commands could be executed to set permissions to the home directory:

```
chown zabbix:zabbix /home/zabbix
chmod 700 /home/zabbix
```

Previously stopped processes can now be started again:

```
systemctl start zabbix-agent
systemctl start zabbix-server
```

Now, the steps to generate the public and private keys can be performed with the following commands (for better readability, command prompts are commented out):

```
sudo -u zabbix ssh-keygen -t rsa
##### Generating public/private rsa key pair.
##### Enter file in which to save the key (/home/zabbix/.ssh/id_rsa):
/home/zabbix/.ssh/id_rsa
##### Enter passphrase (empty for no passphrase):
<Leave empty>
##### Enter same passphrase again:
<Leave empty>
##### Your identification has been saved in /home/zabbix/.ssh/id_rsa.
##### Your public key has been saved in /home/zabbix/.ssh/id_rsa.pub.
##### The key fingerprint is:
##### 90:af:e4:c7:e3:f0:2e:5a:8d:ab:48:a2:0c:92:30:b9 zabbix@it0
##### The key's randomart image is:
##### +--[ RSA 2048 ]-----+
##### |                      |
##### |      .                |
##### |      o                |
##### | .      o              |
##### | +      . S           |
##### | .+    o =            |
##### | E .    * =           |
##### | =o .  . . * .        |
##### | ... oo.o+           |
##### +-----+
#####
```

Note:

The public and private keys (*id_rsa.pub* and *id_rsa*) have been generated by default in the */home/zabbix/.ssh* directory, which corresponds to the *Zabbix server SSHKeyLocation* configuration parameter.

Attention:

Key types other than "rsa" may be supported by the *ssh-keygen* tool and SSH servers but they may not be supported by *libssh2* used by Zabbix.

Shell configuration form

This step should be performed only once for every host that will be monitored by SSH checks.

By using the following commands, the **public** key file can be installed on a remote host `10.10.10.10`, so that the SSH checks can be performed with a `root` account (for better readability, command prompts are commented out):

```
sudo -u zabbix ssh-copy-id root@10.10.10.10
##### The authenticity of host '10.10.10.10 (10.10.10.10)' can't be established.
##### RSA key fingerprint is 38:ba:f2:a4:b5:d9:8f:52:00:09:f7:1f:75:cc:0b:46.
##### Are you sure you want to continue connecting (yes/no)?
yes
##### Warning: Permanently added '10.10.10.10' (RSA) to the list of known hosts.
##### root@10.10.10.10's password:
<Enter root password>
##### Now try logging into the machine, with "ssh 'root@10.10.10.10'",
##### and check to make sure that only the key(s) you wanted were added.
```

Now it is possible to check the SSH login using the default private key (`/home/zabbix/.ssh/id_rsa`) for the `zabbix` user account:

```
sudo -u zabbix ssh root@10.10.10.10
```

If the login is successful, then the configuration part in the shell is finished and the remote SSH session can be closed.

Item configuration

Actual command(s) to be executed must be placed in the *Executed script* field in the item configuration. Multiple commands can be executed one after another by placing them on a new line. In this case returned values will also be formatted as multilined.

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for SSH items are:

| Parameter | Description | Comments |
|-----------|-------------------------------|----------|
| Type | Select SSH agent here. | |

| Parameter | Description | Comments |
|----------------------------|--|---|
| Key | Unique (per host) item key in the format ssh.run[unique short description,<ip>,<port>,<encoding>,<ssh options>,<subsystem>] | <p>unique short description is required and should be unique for each SSH item per host.</p> <p>Default port is 22, not the port specified in the interface to which this item is assigned.</p> <p>ssh options allow to pass additional SSH options in the format <i>key1=value1;key2=value2,value3</i>. Multiple values for one key can be passed separated by comma (in this case, the parameter must be quoted); multiple option keys can be passed separated by semicolon.</p> <p>The following option keys are supported: KexAlgorithms, HostkeyAlgorithms, Ciphers, MACs, PubkeyAcceptedKeyTypes. Option key and value support depends on the SSH library (for example, PubkeyAcceptedKeyTypes is supported only with libssh); if an option is not supported, an error will be returned, and the item will become unsupported.</p> <p>Note that "+" sign for appending cipher settings and "!" for disabling specific cipher settings (as in GnuTLS and OpenSSL) are not supported.</p> <p>Examples:</p> <pre>=> ssh.run[KexAlgorithms,127.0.0.1,,,Ciphers=aes128: => ssh.run[KexAlgorithms,,,,"KexAlgorithms=diffie-h => ssh.run[PubkeyAcceptedKeyTypes,127.0.0.1,,,Pubkey</pre> <p>subsystem allows to pass an SSH subsystem, limiting the SSH connection to specific operations permitted by the subsystem (e.g., file transfers using SFTP or network device management using NETCONF). Note that using a subsystem may also require the use of specific script syntax in the <i>Executed script</i> parameter.</p> <p>Examples:</p> <pre>=> ssh.run[SFTPSBackup,192.0.2.18,,,sftp] => ssh.run[Cisco1234,192.0.2.18,,,netconf]</pre> |
| Authentication method | One of the "Password" or "Public key". | |
| User name | User name (up to 255 characters) to authenticate on remote host. Required. | |
| Public key file | File name of public key if <i>Authentication method</i> is "Public key". Required. | Example: <i>id_rsa.pub</i> - default public key file name generated by a command ssh-keygen . |
| Private key file | File name of private key if <i>Authentication method</i> is "Public key". Required. | Example: <i>id_rsa</i> - default private key file name. |
| Password or Key passphrase | Password (up to 255 characters) to authenticate or Passphrase if it was used for the private key. | <p>Leave the <i>Key passphrase</i> field empty if passphrase was not used.</p> <p>See also known issues regarding passphrase usage.</p> |

| Parameter | Description | Comments |
|------------------------|---|--|
| <i>Executed script</i> | Executed shell command(s) using SSH remote session. | <p>The return value of the executed shell command(s) is limited to 16MB (including trailing whitespace that is truncated); database limits also apply.</p> <p>Note that the libssh2 library may truncate executable scripts to ~32kB.</p> <p>Examples: date +%s systemctl status mysql-server ps auxww \\\ grep httpd \\\ wc -l</p> <p>Example (for NETCONF subsystem): <rpc> <get-software-information/> </rpc>]]>]]> <rpc> <close-session/> </rpc>]]>]]></p> |

10 Telnet checks

Overview

Telnet checks are performed as agent-less monitoring. Zabbix agent is not needed for Telnet checks.

Configurable fields

Actual command(s) to be executed must be placed in the **Executed script** field in the item configuration.

Multiple commands can be executed one after another by placing them on a new line. In this case returned value also will be formatted as multiline.

Supported characters that the shell prompt can end with:

- \$
- #
- >
- %

Note:

A telnet prompt line which ended with one of these characters will be removed from the returned value, but only for the first command in the commands list, i.e. only at a start of the telnet session.

| Key | Description |
|--|--|
| telnet.run[<unique short description>,<ip>,<port>,<encoding>] | Run a command on a remote device using telnet connection |

Attention:

If a telnet check returns a value with non-ASCII characters and in non-UTF8 encoding then the *<encoding>* parameter of the key should be properly specified. See [encoding of returned values](#) page for more details.

11 External checks

Overview

External check is a check executed by Zabbix server by **running a shell script** or a binary. However, when hosts are monitored by a Zabbix proxy, the external checks are executed by the proxy.

External checks do not require any agent running on a host being monitored.

The syntax of the item key is:

```
script[<parameter1>,<parameter2>,...]
```

Where:

| ARGUMENT | DEFINITION |
|---------------------|-------------------------------------|
| script | Name of a shell script or a binary. |
| parameter(s) | Optional command line parameters. |

If you don't want to pass any parameters to the script you may use:

```
script[] or  
script
```

Zabbix server or proxy will search the directory specified for external scripts and execute the command (see `ExternalScripts` parameter in Zabbix **server/proxy** configuration file). The command will be executed under the same user as Zabbix server/proxy, so any access permissions or environment variables should be handled in a wrapper script, if necessary. Permissions on the command should also allow that user to execute it. Only commands in the specified directory are available for execution.

Warning:

Do not overuse external checks, as each script requires starting a fork process by Zabbix server/proxy, and running many scripts can significantly decrease Zabbix performance.

Usage example

Executing the script **check_oracle.sh** with the first parameters '-h'. The second parameter will be replaced by IP address or DNS name, depending on the selection in the host properties.

```
check_oracle.sh["-h","{HOST.CONN}"]
```

Assuming host is configured to use IP address, Zabbix server/proxy will execute:

```
check_oracle.sh '-h' '192.168.1.4'
```

External check result

The return value of an external check is a standard output together with a standard error produced by the check.

Attention:

An item that returns text (character, log, or text type of information) will not become unsupported in case of a standard error output.

The return value is limited to 16MB (including trailing whitespace that is truncated); **database limits** also apply.

If the requested script is not found or Zabbix server/proxy has no permissions to execute it, the item will become unsupported and a corresponding error message will be displayed.

In case of a timeout, the item will become unsupported, a corresponding error message will be displayed, and the process forked for the script will be terminated.

12 Trapper items

Overview

Trapper items accept incoming data instead of querying for it. This is useful for any data you want to send to Zabbix.

Configuration

To configure a trapper item:

1. Go to *Data collection* → *Hosts*.
2. Click *Items* in the row of the host.
3. Click *Create item*.

4. Enter item parameters in the configuration form.

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for trapper items are:

| | |
|---------------------|---|
| Type | Select "Zabbix trapper". |
| Key | Enter a key that will be used to recognize the item when sending data to Zabbix server. |
| Type of information | Select the type of information that will correspond to the format of data that will be sent. |
| Allowed hosts | List of comma-delimited IP addresses (optionally in CIDR notation) or DNS names. If specified, incoming connections will be accepted only from the hosts listed here. If IPv6 support is enabled then '127.0.0.1', '::127.0.0.1', '::ffff:127.0.0.1' are treated equally and '::/0' will allow any IPv4 or IPv6 address. '0.0.0.0/0' can be used to allow any IPv4 address. Note that "IPv4-compatible IPv6 addresses" (0000::/96 prefix) are supported but deprecated by RFC4291 . Example: 127.0.0.1, 192.168.1.0/24, 192.168.3.1-255, 192.168.1-10.1-255, ::1,2001:db8::/32, mysqlserver1, zabbix.example.com, {HOST.HOST} Spaces, user macros , and host macros {HOST.HOST}, {HOST.NAME}, {HOST.IP}, {HOST.DNS}, {HOST.CONN} are supported. |

Note:

Before sending values, you may have to wait up to 60 seconds after saving the item until Zabbix server picks up the changes from a configuration cache update.

Sending data

Sending data to Zabbix server or proxy is possible using the **Zabbix sender** utility or Zabbix sender **protocol**. Sending data to Zabbix server is also possible using the **history.push** API method.

Zabbix sender

For sending data to Zabbix server or proxy using the Zabbix sender utility, you could run the following command to send the "test value":

```
zabbix_sender -z <server IP address> -p 10051 -s "New host" -k trap -o "test value"
```

To send the "test value", the following command options are used:

- -z to specify Zabbix server IP address

- `-p` to specify Zabbix server port number (10051 by default)
- `-s` to specify the host (make sure to use the technical instead of the visible **host name**)
- `-k` to specify the key of the item **configured** in the trapper item
- `-o` to specify the value to send

Attention:

The Zabbix trapper process does not expand macros used in the item key to check the corresponding item key existence for the targeted host.

For more information on the communication between Zabbix sender and Zabbix server or proxy, see *Zabbix sender protocol*.

history.push

For sending data to Zabbix server using the `history.push` API method, you could make the following HTTP POST request containing some test values:

```
curl --request POST \
  --url 'https://example.com/zabbix/api_jsonrpc.php' \
  --header 'Authorization: Bearer 0424bd59b807674191e7d77572075f33' \
  --header 'Content-Type: application/json-rpc' \
  --data '{"jsonrpc":"2.0","method":"history.push","params":[{"itemid":10600,"value":"test value 1"},{"ite
```

If the request is correct, the response returned by API could look as follows:

```
{
  "jsonrpc": "2.0",
  "result": {
    "response": "success",
    "data": [
      {
        "itemid": "10600"
      },
      {
        "itemid": "10601",
        "error": "Item is disabled."
      },
      {
        "error": "No permissions to referred object or it does not exist."
      }
    ]
  },
  "id": 1
}
```

Errors in response data indicate that sending data for specific items has failed validation by Zabbix server. This can happen for the following reasons:

- the user sending the data has no *read* permission to the item's host;
- the host is disabled or in maintenance without data collection;
- the item does not exist or is not yet included in the server configuration cache;
- the item is disabled or its type is other than Zabbix trapper or **HTTP agent** (with trapping enabled);
- the user's IP or DNS is not set in the item's *Allowed hosts* list;
- another item has a value with a duplicate timestamp on the nanosecond level.

The absence of errors indicates that the values sent have been accepted for processing, which includes preprocessing (if any), trigger processing, and saving to the database. Note that the processing of an accepted value may also fail (for example, during **preprocessing**), resulting in the value being discarded.

For more information on how to work with Zabbix API, see *API*.

Displaying data

Once data is sent, you can navigate to *Monitoring* → *Latest data* to see the result:

Latest data

| | | | | |
|--|----------|--------------|------------|------------|
| Subfilter affects only filtered data | | | | |
| HOSTS | | | | |
| New host 1 | | | | |
| DATA | | | | |
| With data Without data | | | | |
| <input type="checkbox"/> | Host | Name ▲ | Last check | Last value |
| <input type="checkbox"/> | New host | Trapper item | 2m 27s | test value |

Note:

If a single numeric value is sent, the data **graph** will show a horizontal line to the left and right of the value's time point.

13 JMX monitoring

Overview

JMX monitoring can be used to monitor JMX counters of a Java application.

JMX monitoring has native support in Zabbix in the form of a Zabbix daemon called "Zabbix Java gateway".

To retrieve the value of a particular JMX counter on a host, Zabbix server queries the Zabbix **Java gateway**, which in turn uses the [JMX management API](#) to query the application of interest remotely.

For more details and setup see the [Zabbix Java gateway](#) section.

Warning:

Communication between Java gateway and the monitored JMX application should not be firewalled.

Enabling remote JMX monitoring for Java application

A Java application does not need any additional software installed, but it needs to be started with the command-line options specified below to have support for remote JMX monitoring.

As a bare minimum, if you just wish to get started by monitoring a simple Java application on a local host with no security enforced, start it with these options:

```
java \
-Dcom.sun.management.jmxremote \
-Dcom.sun.management.jmxremote.port=12345 \
-Dcom.sun.management.jmxremote.authenticate=false \
-Dcom.sun.management.jmxremote.ssl=false \
-Dcom.sun.management.jmxremote.registry.ssl=false \
-jar /path/to/your/application.jar
```

This makes Java listen for incoming JMX connections on port 12345, from local host only, and tells it not to require authentication or SSL.

If you want to allow connections on another interface, set the `-Djava.rmi.server.hostname` parameter to the IP of that interface.

If you wish to be more stringent about security, there are many other Java options available to you. For instance, the next example starts the application with a more versatile set of options and opens it to a wider network, not just local host.

```
java \
-Djava.rmi.server.hostname=192.168.3.14 \
-Dcom.sun.management.jmxremote \
-Dcom.sun.management.jmxremote.port=12345 \
-Dcom.sun.management.jmxremote.authenticate=true \
-Dcom.sun.management.jmxremote.password.file=/etc/java-6-openjdk/management/jmxremote.password \
-Dcom.sun.management.jmxremote.access.file=/etc/java-6-openjdk/management/jmxremote.access \
-Dcom.sun.management.jmxremote.ssl=true \
-Dcom.sun.management.jmxremote.registry.ssl=true \
-Djavax.net.ssl.keyStore=$YOUR_KEY_STORE \
-Djavax.net.ssl.keyStorePassword=$YOUR_KEY_STORE_PASSWORD \
-Djavax.net.ssl.trustStore=$YOUR_TRUST_STORE \
```

```
-Djavax.net.ssl.trustStorePassword=$YOUR_TRUST_STORE_PASSWORD \
-Dcom.sun.management.jmxremote.ssl.need.client.auth=true \
-jar /path/to/your/application.jar
```

Most (if not all) of these settings can be specified in `$JRE/lib/management/management.properties` (or wherever that file is on your system).

Note that if you wish to use SSL, you have to modify `startup.sh` script by adding `-Djavax.net.ssl.*` options to Java gateway, so that it knows where to find key and trust stores.

See [Monitoring and Management Using JMX](#) for a detailed description.

Configuring JMX interfaces and items in Zabbix frontend

With Java gateway running, server knowing where to find it and a Java application started with support for remote JMX monitoring, it is time to configure the interfaces and items in Zabbix GUI.

Configuring JMX interface

You begin by creating a JMX-type interface on the host of interest.

The screenshot shows the Zabbix GUI for configuring a host named 'JMX host'. The 'Host' tab is active. Under the 'Interfaces' section, there are two entries:

| Interfaces | Type | IP address | DNS name | Connect to | Port |
|------------|------|------------|----------|------------|-------|
| Agent | | 127.0.0.1 | | IP | 10050 |
| JMX | | 127.0.0.1 | | IP | 12345 |

An 'Add' link is visible below the table.

All mandatory input fields are marked with a red asterisk.

Adding JMX agent item

For each JMX counter you are interested in you add **JMX agent** item attached to that interface.

The key in the screenshot below says `jmx["java.lang:type=Memory","HeapMemoryUsage.used"]`.

The screenshot shows the Zabbix GUI for configuring a new item. The 'Item' tab is active. The configuration is as follows:

- Name:** Used heap memory
- Type:** JMX agent
- Key:** `jmx["java.lang:type=Memory","HeapMemoryUsage.used"]`
- Type of information:** Numeric (unsigned)
- Host interface:** 127.0.0.1:12345
- JMX endpoint:** `service:jmx:rmi:///jndi/rmi://{HOST.CONN}:{HOST.PORT}/jmxrmi`
- User name:** {JMX_USERNAME}
- Password:** {JMX_PASSWORD}
- Units:**
- Update interval:** 1m

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for JMX items are:

| | |
|--------------|--|
| Type | Set JMX agent here. |
| Key | <p>The <code>jmx[]</code> item key contains three parameters:</p> <p>object name - the object name of an MBean</p> <p>attribute name - an MBean attribute name with optional composite data field names separated by dots</p> <p>unique short description - a unique description that allows multiple JMX items with the same object name and attribute name on the host (optional)</p> <p>See below for more detail on JMX item keys.</p> <p>You may discover MBeans and MBean attributes using a <code>jmx.discovery[]</code> low-level discovery item.</p> |
| JMX endpoint | <p>You may specify a custom JMX endpoint. Make sure that JMX endpoint connection parameters match the JMX interface. This can be achieved by using <code>{HOST.*}</code> macros as done in the default JMX endpoint.</p> <p><code>{HOST.*}</code> macros and user macros are supported.</p> |
| User name | <p>Specify the user name (up to 255 characters), if you have configured authentication on your Java application.</p> <p>User macros are supported.</p> |
| Password | <p>Specify the password (up to 255 characters), if you have configured authentication on your Java application.</p> <p>User macros are supported.</p> |

If you wish to monitor a Boolean counter that is either "true" or "false", then you specify type of information as "Numeric (unsigned)" and select "Boolean to decimal" preprocessing step in the Preprocessing tab. Server will store Boolean values as 1 or 0, respectively.

JMX item keys in more detail

Simple attributes

An MBean object name is nothing but a string which you define in your Java application. An attribute name, on the other hand, can be more complex. In case an attribute returns primitive data type (an integer, a string etc.) there is nothing to worry about, the key will look like this:

```
jmx[com.example:Type=Hello,weight]
```

In this example the object name is "com.example:Type=Hello", the attribute name is "weight", and the returned value type should probably be "Numeric (float)".

Attributes returning composite data

It becomes more complicated when your attribute returns composite data. For example: your attribute name is "apple" and it returns a hash representing its parameters, like "weight", "color" etc. Your key may look like this:

```
jmx[com.example:Type=Hello,apple.weight]
```

This is how an attribute name and a hash key are separated, by using a dot symbol. Same way, if an attribute returns nested composite data the parts are separated by a dot:

```
jmx[com.example:Type=Hello,fruits.apple.weight]
```

Attributes returning tabular data

Tabular data attributes consist of one or multiple composite attributes. If such an attribute is specified in the attribute name parameter then this item value will return the complete structure of the attribute in JSON format. The individual element values inside the tabular data attribute can be retrieved using preprocessing.

Tabular data attribute example:

```
jmx[com.example:type=Hello,foodinfo]
```

Item value:

```
[
  {
    "a": "apple",
    "b": "banana",
    "c": "cherry"
  },
  {
    "a": "potato",
```

```

    "b": "lettuce",
    "c": "onion"
  }
]

```

Problem with dots

So far so good. But what if an attribute name or a hash key contains dot symbol? Here is an example:

```
jmx[com.example:Type=Hello,all.fruits.apple.weight]
```

That's a problem. How to tell Zabbix that attribute name is "all.fruits", not just "all"? How to distinguish a dot that is part of the name from the dot that separates an attribute name and hash keys?

This is possible, all you need to do is to escape the dots that are part of the name with a backslash:

```
jmx[com.example:Type=Hello,all\.fruits.apple.weight]
```

Same way, if your hash key contains a dot you escape it:

```
jmx[com.example:Type=Hello,all\.fruits.apple.total\.weight]
```

Other issues

A backslash character in an attribute name should be escaped:

```
jmx[com.example:type=Hello,c:\\documents]
```

For handling any other special characters in JMX item key, please see the item key format [section](#).

This is actually all there is to it. Happy JMX monitoring!

Non-primitive data types

It is possible to work with custom MBeans returning non-primitive data types, which override the **toString()** method.

Using custom endpoint with JBoss EAP 6.4

Custom endpoints allow working with different transport protocols other than the default RMI.

To illustrate this possibility, let's try to configure JBoss EAP 6.4 monitoring as an example. First, let's make some assumptions:

- You have already installed Zabbix Java gateway. If not, then you can do it in accordance with the [documentation](#).
- Zabbix server and Java gateway are installed with the prefix `/usr/local/`
- JBoss is already installed in `/opt/jboss-eap-6.4/` and is running in standalone mode
- We shall assume that all these components work on the same host
- Firewall and SELinux are disabled (or configured accordingly)

Let's make some simple settings in `zabbix_server.conf`:

```
JavaGateway=127.0.0.1
StartJavaPollers=5
```

And in the `zabbix_java/settings.sh` configuration file (or `zabbix_java_gateway.conf`):

```
START_POLLERS=5
```

Check that JBoss listens to its standard management port:

```
$ netstat -natp | grep 9999
tcp        0      0 127.0.0.1:9999      0.0.0.0:*           LISTEN      10148/java
```

Now let's create a host with JMX interface `127.0.0.1:9999` in Zabbix.

Host Templates IPMI Tags Macros Inventory Encryption Value mapping

* Host name

Visible name

* Groups

| Interfaces | Type | IP address | DNS name | Connect to | Port |
|------------|------|--|----------------------|---|------------------------------------|
| Agent | | <input type="text" value="127.0.0.1"/> | <input type="text"/> | <input checked="" type="button" value="IP"/> <input type="button" value="DNS"/> | <input type="text" value="10050"/> |
| JMX | | <input type="text" value="127.0.0.1"/> | <input type="text"/> | <input checked="" type="button" value="IP"/> <input type="button" value="DNS"/> | <input type="text" value="9999"/> |

[Add](#)

As we know that this version of JBoss uses the JBoss Remoting protocol instead of RMI, we may mass update the JMX endpoint parameter for items in our JMX template accordingly:

```
service:jmx:remoting-jmx://{HOST.CONN}:{HOST.PORT}
```

Mass update

Item Tags Preprocessing

Type ☐ Original

JMX endpoint ☒

Let's update the configuration cache:

```
/usr/local/sbin/zabbix_server -R config_cache_reload
```

Note that you may encounter an error first.

```

```

"Unsupported protocol: remoting-jmx" means that Java gateway does not know how to work with the specified protocol. That can be fixed by creating a `~/needed_modules.txt` file with the following content:

```
jboss-as-remoting
jboss-logging
jboss-logmanager
jboss-marshalling
jboss-remoting
jboss-sasl
jcl-over-slf4j
jul-to-slf4j-stub
log4j-jboss-logmanager
remoting-jmx
slf4j-api
xnio-api
xnio-nio
```

and then executing the command:

```
for i in $(cat ~/needed_modules.txt); do find /opt/jboss-eap-6.4 -iname "${i}*.jar" -exec cp '{}' /usr/local/lib/;
```

Thus, Java gateway will have all the necessary modules for working with jmx-remoting. What's left is to restart the Java gateway, wait a bit and if you did everything right, see that JMX monitoring data begin to arrive in Zabbix (see also: [Latest data](#)).

14 ODBC monitoring

Overview

ODBC monitoring corresponds to the **Database monitor** item type in the Zabbix frontend.

ODBC is a C programming language middle-ware API for accessing database management systems (DBMS). The ODBC concept was developed by Microsoft and later ported to other platforms.

Zabbix may query any database, which is supported by ODBC. To do that, Zabbix does not directly connect to the databases, but uses the ODBC interface and drivers set up in ODBC. This allows for more efficient monitoring of different databases for multiple purposes (for example, checking specific database queues, usage statistics, etc.).

Zabbix supports unixODBC, which is one of the most commonly used open source ODBC API implementations.

Attention:

See also: [known issues](#) for ODBC checks.

Installing unixODBC

The suggested way of installing unixODBC is to use the Linux operating system default package repositories. In the most popular Linux distributions, unixODBC is included in the package repository by default. If packages are not available, the source files can be obtained at the unixODBC homepage: <http://www.unixodbc.org/download.html>.

To install unixODBC, use the package manager for the system of your choice:

```
##### For Ubuntu/Debian systems:
```

```
apt install unixodbc unixodbc-dev
```

```
##### For RedHat/Fedora-based systems:
```

```
dnf install unixODBC unixODBC-devel
```

```
##### For SUSE-based systems:
```

```
zypper in unixODBC-devel
```

Attention:

The unixodbc-dev or unixODBC-devel package is necessary to compile Zabbix with unixODBC support. To enable ODBC support, Zabbix should be compiled with the following **configuration option**: `

--with-unixodbc[=ARG] # Use ODBC driver against unixODBC package.`

Installing unixODBC drivers

The unixODBC database driver should be installed for the database that will be monitored. For a list of supported databases and drivers, see the unixODBC homepage: <http://www.unixodbc.org/drivers.html>.

Note:

In some Linux distributions, database drivers are included in package repositories.

MySQL

To install the MySQL unixODBC database driver, use the package manager for the system of your choice:

For Ubuntu/Debian systems:

```
apt install odbc-mariadb
```

For RedHat/Fedora-based systems:

```
dnf install mariadb-connector-odbc
```

For SUSE-based systems:

```
zypper install mariadb-connector-odbc
```

To install the database driver without a package manager, please refer to [MySQL documentation](#) for `mysql-connector-odbc`, or [MariaDB documentation](#) for `mariadb-connector-odbc`.

PostgreSQL

To install the PostgreSQL unixODBC database driver, use the package manager for the system of your choice:

For Ubuntu/Debian systems:

```
apt install odbc-postgresql
```

For RedHat/Fedora-based systems:

```
dnf install postgresql-odbc
```

For SUSE-based systems:

```
zypper install psqlODBC
```

To install the database driver without a package manager, please refer to [PostgreSQL documentation](#).

Oracle

To install the unixODBC database driver, please refer to [Oracle documentation](#).

MSSQL

To install the MSSQL unixODBC database driver for Ubuntu/Debian systems, use the package manager for the system of your choice:

For Ubuntu/Debian systems:

```
apt install tdsodbc
```

For RedHat/Fedora-based systems (EPEL packages: <https://docs.fedoraproject.org/en-US/epel/>):

```
dnf install epel-release
```

```
dnf install freetds
```

For SUSE-based systems:

```
zypper install libtdsodbc0
```

To install the database driver without a package manager, please refer to [FreeTDS user guide](#).

Configuring unixODBC

To configure unixODBC, you must edit the `odbcinst.ini` and `odbc.ini` files. You can verify the location of these files by executing the following command:

```
odbcinst -j
```

The command result should contain information that is similar to the following:

```
unixODBC 2.3.9
DRIVERS.....: /etc/odbcinst.ini
SYSTEM DATA SOURCES: /etc/odbc.ini
FILE DATA SOURCES...: /etc/ODBCDataSources
```

`odbcinst.ini`

The `odbcinst.ini` file lists the installed ODBC database drivers. If `odbcinst.ini` is missing, it is necessary to create it manually.

```
[TEST_MYSQL]
Description=ODBC for MySQL
Driver=/usr/lib/libmyodbc5.so
FileUsage=1
```

| Parameter | Description |
|-------------|--|
| TEST_MYSQL | Database driver name. |
| Description | Database driver description. |
| Driver | Database driver library location. |
| FileUsage | Determines whether the database driver supports connecting to a database server without the support for accessing local files (0); supports reading data from files (1); supports writing data to files (2). |
| Threading | Thread serialization level. Supported for PostgreSQL. Since 1.6, if the driver manager is built with thread support, you may add another driver entry. |

`odbc.ini`

The `odbc.ini` file is used to configure data sources. Note that the list of supported parameters depends on the database driver (for example, Oracle databases may use `ServerName` instead of `Server`, etc.).

```
[TEST_MYSQL]
Description=MySQL Test Database
Driver=mysql
Server=127.0.0.1
User=root
Password=
Port=3306
Socket=
Database=zabbix
```

| Parameter | Description |
|-------------|--|
| TEST_MYSQL | Data source name (DSN). |
| Description | Data source description. |
| Driver | Database driver name (as specified in <code>odbcinst.ini</code>). |
| Server | Database server IP/DNS. |
| User | Database user for connection. |
| Password | Database user password. |
| Port | Database connection port. |
| Socket | Database connection socket. |
| Database | Database name. |

For other possible configuration parameter options, see [MySQL documentation](#).

The `odbc.ini` file for PostgreSQL may contain additional parameters:

```
[TEST_PSQL]
Description=PostgreSQL Test Database
Driver=postgresql
Username=zb_x_test
Password=zabbix
Servername=127.0.0.1
Database=zabbix
Port=5432
ReadOnly=No
Protocol=7.4+
ShowOidColumn=No
FakeOidIndex=No
RowVersioning=No
ShowSystemTables=No
Fetch=Yes
BoolsAsChar=Yes
```

SSLmode=Require
ConnSettings=

| Parameter | Description |
|------------------|--|
| ReadOnly | Specifies whether the database connection allows only read operations (SELECT queries) and restricts modifications (INSERT, UPDATE, and DELETE statements); useful for scenarios where data should remain unchanged. |
| Protocol | PostgreSQL backend protocol version (ignored when using SSL connections). |
| ShowOidColumn | Specifies whether to include Object ID (OID) in SQLColumns. |
| FakeOidIndex | Specifies whether to create a fake unique index on OID. |
| RowVersioning | Specifies whether to enable applications to detect if data has been modified by other users while you are attempting to update a row. Note that this parameter can speed up the update process, since, to update a row, every single column does not need to be specified in the WHERE clause. |
| ShowSystemTables | Specifies whether the database driver should treat system tables as regular tables in SQLTables; useful for accessibility, allowing visibility into system tables. |
| Fetch | Specifies whether the driver should automatically use declare cursor/fetch to handle SELECT statements and maintain a cache of 100 rows. |
| BoolsAsChar | Controls the mapping of Boolean types. If set to "Yes", Booleans are mapped to SQL_CHAR; otherwise, they are mapped to SQL_BIT. |
| SSLmode | Specifies the SSL mode for the connection. |
| ConnSettings | Additional settings sent to the backend on connection. |

Testing ODBC connection

To test if the ODBC connection is working successfully, you can use the `isql` utility (included in the `unixODBC` package):

```
isql test
+-----+
| Connected! |
|           |
| sql-statement |
| help [tablename] |
| quit       |
|           |
+-----+
```

Item configuration in Zabbix frontend

Configure a **Database monitoring** item.

| | | |
|---------------------|--|---------------------------------------|
| Item | Tags | Preprocessing |
| | | |
| * Name | <input type="text" value="MySQL host count"/> | |
| Type | <input type="text" value="Database monitor"/> | |
| * Key | <input type="text" value="db.odbc.select[mysql-simple-check,test]"/> | <input type="button" value="Select"/> |
| Type of information | <input type="text" value="Numeric (unsigned)"/> | |
| User name | <input type="text" value="zabbix"/> | |
| Password | <input type="password"/> | |
| * SQL query | <input type="text" value="select count(*) from hosts"/> | |
| Units | <input type="text"/> | |
| * Update interval | <input type="text" value="1m"/> | |

All mandatory input fields are marked with a red asterisk.

For database monitoring items, you must specify:

| | |
|---------------------|---|
| Type | Select "Database monitor" here. |
| Key | Enter one of the supported item keys: db.odbc.select[] - this item returns one value (the first column of the first row of the SQL query result); db.odbc.get[] - this item returns multiple rows/columns in JSON format; db.odbc.discovery[] - this item returns low-level discovery data. |
| User name | Enter the database user name (up to 255 characters). This parameter is optional if the database user name is specified in the <code>odbc.ini</code> file. If a connection string is used, and the <i>User name</i> field is not empty, then it is appended to the connection string as <code>UID=<user></code> . |
| Password | Enter the database user password (up to 255 characters). This parameter is optional if the password is specified in the <code>odbc.ini</code> file. If a connection string is used, and the <i>Password</i> field is not empty, then it is appended to the connection string as <code>PWD=<password></code> . Special characters are supported in this field. The password will be appended to connection string after the username as, for example <code>UID=<username>;PWD=P?;)*word</code> . To test the resulting string, you can run the following command: <code>isql -v -k 'Driver=libmaodbc.so;Database=zabbix;UID=zabbix;PWD=P?;)*word'</code> |
| SQL query | Enter the SQL query. Note that with <code>db.odbc.select[]</code> , the query must return one value only. |
| Type of information | Select the type of information that will be returned by the query here. If the type of information is selected incorrectly, the item will become unsupported. |

Important notes

- Database monitoring items will become unsupported if no *odbc poller* processes are started in the server or proxy configuration. To activate ODBC pollers, set the `StartODBCPollers` parameter in Zabbix *server* configuration file or, for checks performed by proxy, in Zabbix *proxy* configuration file.
- The *Timeout* parameter value in the *item configuration* form is used as the ODBC login timeout and the query execution timeout. Note that these timeout settings might be ignored if the installed ODBC driver does not support them.
- The SQL command must return a result set like any query using the `select` statement. The query syntax will depend on the RDBMS which will process them. The syntax of request to a storage procedure must be started with the `call` keyword.

Item key details

Parameters without angle brackets are mandatory. Parameters marked with angle brackets `< >` are optional.

`db.odbc.select[<unique short description>,<dsn>,<connection string>]`

`
` Returns one value, that is, the first column of the first row of the SQL query result.`
` Return value: Depending on the SQL query.

Parameters:

- unique short description** - a unique short description to identify the item (for use in triggers, etc.);
- dsn** - the data source name (as specified in `odbc.ini`);
- connection string** - the connection string (may contain driver-specific arguments).

Comments:

- Although `dsn` and `connection string` are optional parameters, at least one of them is required; if both are defined, `dsn` will be ignored.
- If a query returns more than one column, only the first column is read. If a query returns more than one line, only the first line is read.

`db.odbc.get[<unique short description>,<dsn>,<connection string>]`

`
` Transforms the SQL query result into a JSON array.`
` Return value: *JSON object*.

Parameters:

- unique short description** - a unique short description to identify the item (for use in triggers, etc.);
- dsn** - the data source name (as specified in `odbc.ini`);
- connection string** - the connection string (may contain driver-specific arguments).

Comments:

- Although `dsn` and `connection string` are optional parameters, at least one of them is required; if both are defined, `dsn` will be ignored.
- Multiple rows/columns in JSON format may be returned. This item may be used as a master item that collects all data in one system call, while `JSONPath` preprocessing may be used in dependent items to extract individual values. For more information, see an [example](#) of the returned format, used in low-level discovery.

Example:

```
# Connection for MySQL ODBC driver 5:
db.odbc.get[MySQL example,, "Driver=/usr/local/lib/libmyodbc5a.so;Database=master;Server=127.0.0.1;Port=3306"]
db.odbc.discovery[<unique short description>,<dsn>,<connection string>]
```

 Transforms the SQL query result into a JSON array, used for [low-level discovery](#). The column names from the query result are turned into low-level discovery macro names paired with the discovered field values. These macros can be used in creating item, trigger, etc. prototypes.
 Return value: *JSON object*.

Parameters:

- **unique short description** - a unique short description to identify the item (for use in triggers, etc.);
- **dsn** - the data source name (as specified in `odbc.ini`);
- **connection string** - the connection string (may contain driver-specific arguments).

Comments:

- Although `dsn` and `connection string` are optional parameters, at least one of them is required; if both are defined, `dsn` will be ignored.

Error messages

ODBC error messages are structured into fields to provide detailed information. For example, an error message might look like this:

```
Cannot execute ODBC query: [SQL_ERROR]:[42601][7][ERROR: syntax error at or near ";"; Error while executing the query]
```

- "Cannot execute ODBC query" - Zabbix message
- "[SQL_ERROR]" - ODBC return code
- "[42601]" - SQLState
- "[7]" - Native error code
- "[ERROR: syntax error at or near ";"; Error while executing the query]" - Native error message

Note that the error message length is limited to 2048 bytes, so the message can be truncated. If there is more than one ODBC diagnostic record, Zabbix tries to concatenate them (separated with `|`) as far as the length limit allows.

15 Dependent items

Overview

There are situations when one item gathers multiple metrics at a time or it even makes more sense to collect related metrics simultaneously, for example:

- CPU utilization of individual cores
- Incoming/outgoing/total network traffic

To allow for bulk metric collection and simultaneous use in several related items, Zabbix supports dependent items. Dependent items depend on the master item that collects their data simultaneously, in one query. A new value for the master item automatically populates the values of the dependent items. Dependent items cannot have a different update interval than the master item.

Zabbix preprocessing options can be used to extract the part that is needed for the dependent item from the master item data.

Preprocessing is managed by a `preprocessing manager` process, along with worker threads that perform the preprocessing steps. All values (with or without preprocessing) from different data gatherers pass through the preprocessing manager before being added to the history cache. Socket-based IPC communication is used between data gatherers (pollers, trappers, etc) and the preprocessing process.

Zabbix server or Zabbix proxy (if host is monitored by proxy) are performing preprocessing steps and processing dependent items.

Item of any type, even dependent item, can be set as master item. Additional levels of dependent items can be used to extract smaller parts from the value of an existing dependent item.

Limitations

- Only same host (template) dependencies are allowed
- An item prototype can depend on another item prototype or regular item from the same host
- Dependent item on a host with master item from template will not be exported to XML

Item configuration

A dependent item depends on its master item for data. That is why the **master item** must be configured (or exist) first:

- Go to: *Data collection* → *Hosts*
- Click on *Items* in the row of the host
- Click on *Create item*
- Enter parameters of the item in the form

The screenshot shows the 'Create item' form in Zabbix. The 'Item' tab is active. The form contains the following fields:

- Name** (mandatory): Apache server status
- Type**: Zabbix agent
- Key** (mandatory): web.page.get[127.0.0.1/server-status]
- Type of information**: Text
- Host interface** (mandatory): 127.0.0.1:1050
- Update interval** (mandatory): 30s

All mandatory input fields are marked with a red asterisk.

Click on *Add* to save the master item.

Then you can configure a **dependent item**.

The screenshot shows the 'Create item' form in Zabbix for a dependent item. The 'Item' tab is active. The form contains the following fields:

- Name** (mandatory): Apache server uptime
- Type**: Dependent item
- Key** (mandatory): apache.server.uptime
- Type of information**: Text
- Master item** (mandatory): Apache: Apache server status

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for dependent items are:

| | |
|----------------------------|---|
| <i>Type</i> | Select Dependent item here. |
| <i>Key</i> | Enter a key that will be used to recognize the item. |
| <i>Master item</i> | Select the master item. Master item value will be used to populate dependent item value. |
| <i>Type of information</i> | Select the type of information that will correspond the format of data that will be stored. |

You may use item value **preprocessing** to extract the required part of the master item value.

Item

Tags

Preprocessing 1

Preprocessing steps

Display

In the item list dependent items are displayed with their master item name as prefix.

| <input type="checkbox"/> | Name ▲ | Triggers | Key |
|--------------------------|--------|--|---------------------------------------|
| <input type="checkbox"/> | ... | Apache server status | web.page.get[127.0.0.1/server-status] |
| <input type="checkbox"/> | ... | Apache server status: Apache server uptime | apache.server.uptime |

If a master item is deleted, so are all its dependent items.

16 HTTP agent

Overview

This item type allows data polling using the HTTP/HTTPS protocol. Trapping is also possible using the **Zabbix sender** utility or Zabbix sender **protocol** (for sending data to Zabbix server or proxy), or using the **history.push** API method (for sending data to Zabbix server).

HTTP item checks are executed by Zabbix server. However, when hosts are monitored by a Zabbix proxy, HTTP item checks are executed by the proxy.

HTTP item checks do not require any agent running on a host being monitored.

HTTP agent supports both HTTP and HTTPS. Zabbix will optionally follow redirects (see the *Follow redirects* option below). Maximum number of redirects is hard-coded to 10 (using cURL option CURLOPT_MAXREDIRS).

Attention:

Zabbix server/proxy must be initially configured with cURL (libcurl) support.

HTTP checks are executed asynchronously - it is not required to receive the response to one request before other checks are started. DNS resolving is asynchronous as well.

The maximum concurrency of asynchronous checks is 1000 (defined by `MaxConcurrentChecksPerPoller`).

The number of asynchronous HTTP agent pollers is defined by the `StartHTTPAgentPollers` parameter.

The persistent connections cURL feature has been added to HTTP agent checks since Zabbix 7.0.

Configuration

To configure an HTTP item:

- Go to: *Data collection* → *Hosts*
- Click on *Items* in the row of the host
- Click on *Create item*
- Enter parameters of the item in the form

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for HTTP items are:

| Parameter | Description |
|------------------------------|---|
| <i>Type</i> | Select HTTP agent here. |
| <i>Key</i> | Enter a unique item key. |
| <i>URL</i> | <p>URL to connect to and retrieve data. For example: https://www.example.com http://www.example.com/download</p> <p>Domain names can be specified in Unicode characters. They are automatically punycode-converted to ASCII when executing the HTTP check.</p> <p>The <i>Parse</i> button can be used to separate optional query fields (like <code>?name=Admin&password=mypassword</code>) from the URL, moving the attributes and values into <i>Query fields</i> for automatic URL-encoding.</p> <p>Limited to 2048 characters.</p> <p>Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros.</p> |
| <i>Query fields</i> | <p>This sets the CURLOPT_URL cURL option.</p> <p>Variables for the URL (see above).</p> <p>Specified as attribute and value pairs.</p> <p>Values are URL-encoded automatically. Values from macros are resolved and then URL-encoded automatically.</p> <p>Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros.</p> |
| <i>Request type</i> | Select request method type: <i>GET</i> , <i>POST</i> , <i>PUT</i> or <i>HEAD</i> |
| <i>Request body type</i> | <p>Select the request body type:</p> <p>Raw data - custom HTTP request body, macros are substituted but no encoding is performed</p> <p>JSON data - HTTP request body in JSON format. Macros can be used as string, number, true and false; macros used as strings must be enclosed in double quotes. Values from macros are resolved and then escaped automatically. If "Content-Type" is not specified in headers then it will default to "Content-Type: application/json"</p> <p>XML data - HTTP request body in XML format. Macros can be used as a text node, attribute or CDATA section. Values from macros are resolved and then escaped automatically in a text node and attribute. If "Content-Type" is not specified in headers then it will default to "Content-Type: application/xml"</p> <p><i>Note that selecting XML data requires libxml2.</i></p> |
| <i>Request body</i> | <p>Enter the request body.</p> <p>Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros.</p> |
| <i>Headers</i> | <p>Custom HTTP headers that will be sent when performing a request.</p> <p>Specified as attribute and value pairs.</p> <p>Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros.</p> |
| <i>Required status codes</i> | <p>This sets the CURLOPT_HTTPHEADER cURL option.</p> <p>List of expected HTTP status codes. If Zabbix gets a code which is not in the list, the item will become unsupported. If empty, no check is performed.</p> <p>For example: 200,201,210-299</p> <p>Supported macros in the list: user macros, low-level discovery macros.</p> |
| <i>Follow redirects</i> | <p>This uses the CURLINFO_RESPONSE_CODE cURL option.</p> <p>Mark the checkbox to follow HTTP redirects.</p> |
| <i>Retrieve mode</i> | <p>This sets the CURLOPT_FOLLOWLOCATION cURL option.</p> <p>Select the part of response that must be retrieved:</p> <p>Body - body only</p> <p>Headers - headers only</p> <p>Body and headers - body and headers</p> |

| Parameter | Description |
|-----------------------------|--|
| <i>Convert to JSON</i> | <p>Headers are saved as attribute and value pairs under the "header" key. If 'Content-Type: application/json' is encountered then body is saved as an object, otherwise it is stored as string, for example:</p> <pre> { "header": { "<key>": "<value>", "<key2>": "<value>" }, "body": <body> }</pre> |
| <i>HTTP proxy</i> | <p>You can specify an HTTP proxy to use, using the format [protocol://] [username[:password]@]proxy.example.com[:port]. The optional protocol:// prefix may be used to specify alternative proxy protocols (e.g. https, socks4, socks5; see documentation; the protocol prefix support was added in cURL 7.21.7). With no protocol specified, the proxy will be treated as an HTTP proxy. If you specify the wrong protocol, the connection will fail and the item will become unsupported. By default, 1080 port will be used. If specified, the proxy will overwrite proxy related environment variables like http_proxy, HTTPS_PROXY. If not specified, the proxy will not overwrite proxy-related environment variables. The entered value is passed on "as is", no sanity checking takes place. Note that only simple authentication is supported with HTTP proxy. Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros. This sets the CURLOPT_PROXY cURL option.</p> |
| <i>HTTP authentication</i> | <p>Select the authentication option: None - no authentication used; Basic - basic authentication is used; NTLM - NTLM (Windows NT LAN Manager) authentication is used; Kerberos - Kerberos authentication is used (see also: Configuring Kerberos with Zabbix); Digest - Digest authentication is used. This sets the CURLOPT_HTTPAUTH cURL option.</p> |
| <i>User name</i> | <p>Enter the user name (up to 255 characters). This field is available if <i>HTTP authentication</i> is set to Basic, NTLM, Kerberos, or Digest. User macros and low-level discovery macros are supported.</p> |
| <i>Password</i> | <p>Enter the user password (up to 255 characters). This field is available if <i>HTTP authentication</i> is set to Basic, NTLM, Kerberos, or Digest. User macros and low-level discovery macros are supported.</p> |
| <i>SSL verify peer</i> | <p>Mark the checkbox to verify the SSL certificate of the web server. The server certificate will be automatically taken from system-wide certificate authority (CA) location. You can override the location of CA files using Zabbix server or proxy configuration parameter SSLCAlocation. This sets the CURLOPT_SSL_VERIFYPEER cURL option.</p> |
| <i>SSL verify host</i> | <p>Mark the checkbox to verify that the Common Name field or the Subject Alternate Name field of the web server certificate matches. This sets the CURLOPT_SSL_VERIFYHOST cURL option.</p> |
| <i>SSL certificate file</i> | <p>Name of the SSL certificate file used for client authentication. The certificate file must be in PEM¹ format. If the certificate file contains also the private key, leave the SSL key file field empty. If the key is encrypted, specify the password in SSL key password field. The directory containing this file is specified by Zabbix server or proxy configuration parameter SSLCertLocation. Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros. This sets the CURLOPT_SSLCERT cURL option.</p> |

| Parameter | Description |
|-------------------------|---|
| <i>SSL key file</i> | Name of the SSL private key file used for client authentication. The private key file must be in PEM ¹ format. The directory containing this file is specified by Zabbix server or proxy configuration parameter <code>SSLKeyLocation</code> . Supported macros: {HOST.IP}, {HOST.CONN}, {HOST.DNS}, {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {ITEM.ID}, {ITEM.KEY}, {ITEM.KEY.ORIG}, user macros, low-level discovery macros. This sets the <code>CURLOPT_SSLKEY</code> cURL option. |
| <i>SSL key password</i> | SSL private key file password. Supported macros: user macros, low-level discovery macros. This sets the <code>CURLOPT_KEYPASSWD</code> cURL option. |
| <i>Timeout</i> | Zabbix will not spend more than the set amount of time on processing the URL (1-600 seconds). Actually this parameter defines the maximum time for making a connection to the URL and maximum time for performing an HTTP request. Therefore, Zabbix will not spend more than 2 x <i>Timeout</i> seconds on one check. This sets the <code>CURLOPT_TIMEOUT</code> cURL option. For more information on the <i>Timeout</i> parameter, see general item attributes . |
| <i>Enable trapping</i> | With this checkbox marked, the item will also function as a trapper item and will accept data sent to Zabbix server or proxy using the Zabbix sender utility or Zabbix sender protocol , or will accept data sent to Zabbix server using the history.push API method. For more information about sending data, see: Trapper items . |
| <i>Allowed hosts</i> | Visible only if <i>Enable trapping</i> checkbox is marked. List of comma delimited IP addresses, optionally in CIDR notation, or DNS names. If specified, incoming connections will be accepted only from the hosts listed here. If IPv6 support is enabled then '127.0.0.1', '::127.0.0.1', '::ffff:127.0.0.1' are treated equally and '::/0' will allow any IPv4 or IPv6 address. '0.0.0.0/0' can be used to allow any IPv4 address. Note that "IPv4-compatible IPv6 addresses" (0000::/96 prefix) are supported but deprecated by RFC4291 . Example: 127.0.0.1, 192.168.1.0/24, 192.168.3.1-255, 192.168.1-10.1-255, ::1,2001:db8::/32, mysqlserver1, zabbix.example.com, {HOST.HOST} Spaces and user macros are allowed in this field. Host macros: {HOST.HOST}, {HOST.NAME}, {HOST.IP}, {HOST.DNS}, {HOST.CONN} are allowed in this field. |

Note:

If the *HTTP proxy* field is left empty, another way for using an HTTP proxy is to set proxy-related environment variables. For HTTP - set the `http_proxy` environment variable for the Zabbix server user. For example:
`http_proxy=http://proxy_ip:proxy_port`.
For HTTPS - set the `HTTPS_PROXY` environment variable. For example:
`HTTPS_PROXY=http://proxy_ip:proxy_port`. More details are available by running a shell command: `# man curl`.

Attention:

[1] Zabbix supports certificate and private key files in PEM format only. In case you have your certificate and private key data in PKCS #12 format file (usually with extension *.p12 or *.pfx) you may generate the PEM file from it using the following commands:
`openssl pkcs12 -in ssl-cert.p12 -clcerts -nokeys -out ssl-cert.pem`
`openssl pkcs12 -in ssl-cert.p12 -nocerts -nodes -out ssl-cert.key`

Examples

Example 1

Send simple GET requests to retrieve data from services such as Elasticsearch:

- Create a GET item with URL: `localhost:9200/?pretty`
- Notice the response:

```
{
  "name" : "YQ2VAY-",
  "cluster_name" : "elasticsearch",
  "cluster_uuid" : "kH4CYqh5QfqgeTsjh2F9zg",
```

```

"version" : {
  "number" : "6.1.3",
  "build_hash" : "af51318",
  "build_date" : "2018-01-26T18:22:55.523Z",
  "build_snapshot" : false,
  "lucene_version" : "7.1.0",
  "minimum_wire_compatibility_version" : "5.6.0",
  "minimum_index_compatibility_version" : "5.0.0"
},
>tagline" : "You know, for search"
}

```

- Now extract the version number using a JSONPath preprocessing step: \$.version.number

Example 2

Send simple POST requests to retrieve data from services such as Elasticsearch:

- Create a POST item with URL: http://localhost:9200/str/values/_search?scroll=10s
- Configure the following POST body to obtain the processor load (1 min average per core)

```

{
  "query": {
    "bool": {
      "must": [{
        "match": {
          "itemid": 28275
        }
      }],
      "filter": [{
        "range": {
          "clock": {
            "gt": 1517565836,
            "lte": 1517566137
          }
        }
      }]
    }
  }
}

```

- Received:

```

{
  "_scroll_id": "DnF1ZXJ5VGhlbkZldGNoBQAAAAAAAAAAkF1lRM1ZBWS1UU1pxTmdEeGVwQjRBTfEAAAAAAAAAJRZZUTJWQVh",
  "took": 18,
  "timed_out": false,
  "_shards": {
    "total": 5,
    "successful": 5,
    "skipped": 0,
    "failed": 0
  },
  "hits": {
    "total": 1,
    "max_score": 1.0,
    "hits": [{
      "_index": "dbl",
      "_type": "values",
      "_id": "dqX9VWEbV6sEKSMYk6sw",
      "_score": 1.0,
      "_source": {
        "itemid": 28275,
        "value": "0.138750",
        "clock": 1517566136,
        "ns": 25388713,

```

```

    "ttl": 604800
  }
}
}
}

```

- Now use a JSONPath preprocessing step to get the item value: `$.hits.hits[0]._source.value`

Example 3

Checking if Zabbix API is alive, using `apiinfo.version`.

| lon | { \$LON } | Remove |
| APPID | { \$WEATHER_APIKEY } | Remove |
| lang | { \$WEATHER_LANG } | Remove |

Add

Request type
GET

Request body type
Raw data
JSON data
XML data

Note the usage of macros in query fields. Refer to the [Openweathermap API](#) for how to fill them.

Sample JSON returned in response to HTTP agent:

```
{
  "body": {
    "coord": {
      "lon": 40.01,
      "lat": 56.11
    },
    "weather": [{
      "id": 801,
      "main": "Clouds",
      "description": "few clouds",
      "icon": "02n"
    }],
    "base": "stations",
    "main": {
      "temp": 15.14,
      "pressure": 1012.6,
      "humidity": 66,
```

```

        "temp_min": 15.14,
        "temp_max": 15.14,
        "sea_level": 1030.91,
        "grnd_level": 1012.6
    },
    "wind": {
        "speed": 1.86,
        "deg": 246.001
    },
    "clouds": {
        "all": 20
    },
    "dt": 1526509427,
    "sys": {
        "message": 0.0035,
        "country": "RU",
        "sunrise": 1526432608,
        "sunset": 1526491828
    },
    "id": 487837,
    "name": "Stavrovo",
    "cod": 200
}
}

```

The next task is to configure dependent items that extract data from the JSON.

- Configure a sample dependent item for humidity:

| Item | Tags | Preprocessing |
|--|------|---------------|
| <div> <div>* Name</div> <input type="text" value="Humidity"/> </div> | | |
| <div> <div>Type</div> <div>Dependent item ▼</div> </div> | | |
| <div> <div>* Key</div> <input type="text" value="humidity"/> </div> | | |
| <div> <div>Type of information</div> <div>Numeric (float) ▼</div> </div> | | |
| <div> <div>* Master item</div> <div>Apache: Get weather X</div> </div> | | |
| <div> <div>Units</div> <input type="text"/> </div> | | |

Other weather metrics such as 'Temperature' are added in the same manner.

- Sample dependent item value preprocessing with JSONPath:

| Item | Tags | Preprocessing 1 |
|---|------|-----------------|
| <div> <div>Preprocessing steps</div> <div>Name</div> <div>Parameters</div> </div> | | |
| <div> <div>1: JSONPath ▼</div> <div>\$body.main.humidity</div> </div> | | |
| <div> <div>Add</div> </div> | | |

- Check the result of weather data in *Latest data*:

| ▼ <input type="checkbox"/> Host | Name ▲ | Inter... | History | Trends | Type | Last check | Last value |
|------------------------------------|---|----------|---------|--------|------------|---------------------|--------------------------|

17 Prometheus checks

Overview

Zabbix can query metrics exposed in the Prometheus line format.

Two steps are required to start gathering Prometheus data:

- an **HTTP master item** pointing to the appropriate data endpoint, e.g. `https://<prometheus host>/metrics`
- dependent items using a Prometheus preprocessing option to query required data from the metrics gathered by the master item

There are two Prometheus data preprocessing options:

- Prometheus pattern* - used in normal items to query Prometheus data
- Prometheus to JSON* - used in normal items and for low-level discovery. In this case queried Prometheus data are returned in a JSON format.

Bulk processing

Bulk processing is supported for dependent items. To enable caching and indexing, the *Prometheus pattern* preprocessing must be the **first** preprocessing step. When *Prometheus pattern* is first preprocessing step then the parsed Prometheus data is cached and indexed by the first `<label>==<value>` condition in the *Prometheus pattern* preprocessing step. This cache is reused when

processing other dependent items in this batch. For optimal performance, the first label should be the one with most different values.

If there is other preprocessing to be done before the first step, it should be moved either to the master item or to a new dependent item which would be used as the master item for the dependent items.

Configuration

Providing you have the HTTP master item configured, you need to create a **dependent item** that uses a Prometheus preprocessing step:

- Enter general dependent item parameters in the configuration form
- Go to the Preprocessing tab
- Select a Prometheus preprocessing option (*Prometheus pattern* or *Prometheus to JSON*)

The following parameters are specific to the *Prometheus pattern* preprocessing option:

| Parameter | Description | Examples |
|----------------|--|--|
| <i>Pattern</i> | <p>To define the required data pattern you may use a query language that is similar to Prometheus query language (see comparison table), e.g.:</p> <p><metric name> - select by metric name</p> <p>{__name__="<metric name>"} - select by metric name</p> <p>{__name__=~"<regex>"} - select by metric name matching a regular expression</p> <p>{<label name>="<label value>","..."} - select by label name</p> <p>{<label name>=~"<regex>","..."} - select by label name matching a regular expression</p> <p>{__name__=~".*"}==<value> - select by metric value</p> <p>Or a combination of the above:</p> <p><metric name>{<label1 name>="<label1 value>",<label2 name>=~"<regex>","..."}==<value></p> <p>Label value can be any sequence of UTF-8 characters, but the backslash, double-quote and line feed characters have to be escaped as \\, \" and \n respectively; other characters shall not be escaped.</p> | <pre>wmi_os_physical_memory_free_bytes cpu_usage_system{cpu="cpu-total"} cpu_usage_system{cpu=~".*"} cpu_usage_system{cpu="cpu-total",host=~".*"} wmi_service_state{name="dhcp"}==1 wmi_os_timezone{timezone=~".*"}==1</pre> |

| Parameter | Description | Examples |
|--------------------------|---|--|
| <i>Result processing</i> | Specify whether to return the value, the label or apply the appropriate function (if the pattern matches several lines and the result needs to be aggregated): value - return metric value (error if multiple lines matched) label - return value of the label specified in the <i>Label</i> field (error if multiple metrics are matched) sum - return the sum of values min - return the minimum value max - return the maximum value avg - return the average value count - return the count of values This field is only available for the <i>Prometheus pattern</i> option. | See also examples of using parameters below. |
| <i>Output</i> | Define label name (optional). In this case the value corresponding to the label name is returned. This field is only available for the <i>Prometheus pattern</i> option, if 'Label' is selected in the <i>Result processing</i> field. | |

Examples of using parameters

1. The most common use case is to return the **value**. To return the value of `/var/db` from:

```
node_disk_usage_bytes{path="/var/cache"} 2.1766144e+09<br>node_disk_usage_bytes{path="/var/db"} 20480<br>node_disk_usage_bytes{path="/var/dpkg"} 8192<br>node_disk_usage_bytes{path="/var/empty"} 4096
```

use the following parameters:

- *Pattern* - `node_disk_usage_bytes{path="/var/db"}`
- *Result processing* - select 'value'

2. You may also be interested in the **average** value of all `node_disk_usage_bytes` parameters:

- *Pattern* - `node_disk_usage_bytes`
- *Result processing* - select 'avg'

3. While Prometheus supports only numerical data, it is popular to use a workaround that allows to return the relevant textual description as well. This can be accomplished with a filter and specifying the label. So, to return the value of the 'color' label from

```
elasticsearch_cluster_health_status{cluster="elasticsearch",color="green"} 1<br>elasticsearch_cluster_health_status{cluster="elasticsearch",color="yellow"} 0
```

use the following parameters:

- *Pattern* - `elasticsearch_cluster_health_status {cluster="elasticsearch"} == 1`
- *Result processing* - select 'label'
- *Label* - specify 'color'

The filter (based on the numeric value '1') will match the appropriate row, while the label will return the health status description (currently 'green'; but potentially also 'red' or 'yellow').

Prometheus to JSON

Data from Prometheus can be used for low-level discovery. In this case data in JSON format are needed and the *Prometheus to JSON* preprocessing option will return exactly that.

For more details, see [Discovery using Prometheus data](#).

Query language comparison

The following table lists differences and similarities between PromQL and Zabbix Prometheus preprocessing query language.

| PromQL instant vector selector | Zabbix Prometheus preprocessing |
|--------------------------------|---------------------------------|
| Differences | |

| PromQL instant vector selector | | Zabbix Prometheus preprocessing |
|---|--|--|
| Query target | Prometheus server | Plain text in Prometheus exposition format |
| Returns | Instant vector | Metric or label value (Prometheus pattern) Array of metrics for single value in JSON (Prometheus to JSON) |
| Label matching operators | =, !=, =~, !~ | =, !=, =~, !~ |
| Regular expression used in label or metric name matching | RE2 | PCRE |
| Comparison operators | See list | Only == (equal) is supported for value filtering |
| Similarities | | |
| Selecting by metric name that equals string | <metric name> or {__name__="<metric name>"} | <metric name> or {__name__="<metric name>"} |
| Selecting by metric name that matches regular expression | {__name__=~"<regex>"} | {__name__=~"<regex>"} |
| Selecting by <label name> value that equals string | {<label name>="<label value>","...} | {<label name>="<label value>","...} |
| Selecting by <label name> value that matches regular expression | {<label name>=~"<regex>","...} | {<label name>=~"<regex>","...} |
| Selecting by value that equals string | {__name__=~".*" } == <value> | {__name__=~".*" } == <value> |

18 Script items

Overview

Script items can be used to collect data by executing a user-defined JavaScript code with the ability to retrieve data over HTTP/HTTPS. In addition to the script, an optional list of parameters (pairs of name and value) and timeout can be specified.

This item type may be useful in data collection scenarios that require multiple steps or complex logic. As an example, a Script item can be configured to make an HTTP call, then process the data received in the first step in some way, and pass transformed value to the second HTTP call.

Script items are processed by Zabbix server or proxy pollers.

Configuration

In the *Type* field of [item configuration form](#) select Script then fill out required fields.

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for Script items are:

| Field | Description |
|-------------------|---|
| <i>Key</i> | Enter a unique key that will be used to identify the item. |
| <i>Parameters</i> | Specify the variables to be passed to the script as the attribute and value pairs. User macros are supported. To see which built-in macros are supported, do a search for "Script-type item" in the supported macro table. |
| <i>Script</i> | Enter JavaScript code in the modal editor that opens when clicking in the parameter field or on the pencil icon next to it. This code must provide the logic for returning the metric value. The code has access to all parameters and all additional JavaScript objects added by Zabbix. See also: JavaScript Guide . |
| <i>Timeout</i> | JavaScript execution timeout (1-600s; exceeding it will return an error). Note that depending on the script, it might take longer for the timeout to trigger. For more information on the <i>Timeout</i> parameter, see general item attributes . |

Examples

Simple data collection

Collect the content of `https://www.example.com/release` notes:

- Create an item with type "Script".
- In the *Script* field, enter:

```
var request = new HttpRequest();  
return request.get("https://www.example.com/release_notes");
```

Data collection with parameters

Collect the content of a specific page and make use of parameters:

- Create an item with type "Script" and two parameters:
 - **url** : **{ \$DOMAIN }** (the user macro { \$DOMAIN } should be defined, preferably on the host level)
 - **subpage** : **/release_notes**

Item Tags Preprocessing

* Name

Type

* Key

Type of information

| Name | Value | Action |
|--------------------------------------|---|------------------------|
| <input type="text" value="url"/> | <input type="text" value="{ \$DOMAIN }"/> | Remove |
| <input type="text" value="subpage"/> | <input type="text" value="/release_notes"/> | Remove |
| Add | | |

* Script

- In the *Script* field, enter:

```
var obj = JSON.parse(value);
var url = obj.url;
var subpage = obj.subpage;
var request = new HttpRequest();
return request.get(url + subpage);
```

Multiple HTTP requests

Collect the content of both `https://www.example.com` and `https://www.example.com/release_notes`:

- Create an item with type "Script".
- In the *Script* field, enter:

```
var request = new HttpRequest();
return request.get("https://www.example.com") + request.get("https://www.example.com/release_notes");
```

Logging

Add the "Log test" entry to the Zabbix server log and receive the item value "1" in return:

- Create an item with type "Script".
- In the *Script* field, enter:

```
Zabbix.log(3, 'Log test');
return 1;
```

19 Browser items

Overview

Browser items allow monitoring complex websites and web applications using a browser.

Attention:

The support of Browser items is currently experimental.

Browser items collect data by executing a user-defined JavaScript code and retrieving data over HTTP/HTTPS. This item can simulate such browser-related actions as clicking, entering text, navigating through web pages, and other user interactions with websites or web applications.

In addition to the script, an optional list of parameters (pairs of name and value) and timeout can be specified.

Attention:

The item partially implements the [W3C WebDriver standard](#) with either Selenium Server or a plain WebDriver (for example, ChromeDriver) as a web testing endpoint. For the item to work, set the endpoint in the Zabbix [server/proxy](#) configuration file `WebDriverURL` parameter (if using ChromeDriver, see [Security Considerations](#)). For better performance, consider using a dedicated server for the web testing environment.

Browser item checks are executed and processed by Zabbix server or proxy browser pollers. If necessary, you can adjust the number of pre-forked instances of browser pollers in the Zabbix [server/proxy](#) configuration file `StartBrowserPollers` parameter.

For monitoring complex websites and web applications, the [Website by Browser](#) template is available as an **out-of-the-box template**.

Configuration

In the **Type** field of [item configuration form](#), select **Browser** and then fill out the required fields.

All mandatory input fields are marked with a red asterisk.

The fields that require specific information for Browser items are:

| Field | Description |
|-------|--|
| Key | Enter a unique key that will be used to identify the item. |

| Field | Description |
|-------------------|---|
| <i>Parameters</i> | Specify the variables to be passed to the script as the attribute and value pairs. User macros are supported. To see which built-in macros are supported, do a search for "Browser-type item" in the supported macro table. |
| <i>Script</i> | Enter JavaScript code in the modal editor that opens when clicking in the parameter field or on the pencil icon next to it. This code must provide the logic for returning the metric value. The code has access to all parameters, all additional JavaScript objects and Browser item JavaScript objects added by Zabbix. See also: JavaScript Guide . |
| <i>Timeout</i> | JavaScript execution timeout (1-600s; exceeding it will return an error). Note that depending on the script, it might take longer for the timeout to trigger. For more information on the <i>Timeout</i> parameter, see general item attributes . |

Examples

For an example of how to set up Zabbix for monitoring websites using the *Website by Browser* template, see **Monitor websites with Browser items**.

Default script

The following script:

1. Initializes a browser session.
2. Navigates to a specified URL.
3. Collects performance entries and session statistics, and returns them as a JSON string.

In the *Script* field, enter:

```
var browser = new Browser(Browser.chromeOptions());

try {
    browser.navigate("http://example.com");
    browser.collectPerfEntries();
}
finally {
    return JSON.stringify(browser.getResult());
}
```

Initialize browser with custom capabilities

The following script:

1. Initializes a browser session for the available browser based on the first matching browser in the order specified within the script.
2. Defines browser capabilities, including page load strategy and options specific to each browser, such as the headless mode for Chrome, Firefox, and Microsoft Edge browsers.

In the *Script* field, enter:

```
var browser = new Browser({
    "capabilities":{
        "firstMatch":[
            {
                "browserName":"chrome",
                "pageLoadStrategy":"normal",
                "goog:chromeOptions":{
                    "args":[
                        "--headless=new"
                    ]
                }
            },
            {
                "browserName":"firefox",
                "pageLoadStrategy":"normal",
                "moz:firefoxOptions":{
                    "args":[
                        "--headless"
                    ]
                }
            }
        ]
    }
})
```

```

    ]
  },
  {
    "browserName": "MicrosoftEdge",
    "pageLoadStrategy": "normal",
    "ms:edgeOptions": {
      "args": [
        "--headless=new"
      ]
    }
  },
  {
    "browserName": "safari",
    "pageLoadStrategy": "normal"
  }
]
});

```

Initialize browser with GUI

By default, browser sessions (excluding Safari) are initialized in headless mode, meaning the browser's graphical user interface (GUI) is not displayed.

The following script initializes a browser session with the GUI enabled.

Note that if the WebDriver cannot locate the browser binary, you can specify the path manually.

```

var opts = Browser.chromeOptions();
opts.capabilities.alwaysMatch['goog:chromeOptions'].args = [];

// To initialize a Firefox session with GUI, uncomment the following lines:
// var opts = Browser.firefoxOptions();
// opts.capabilities.alwaysMatch['moz:firefoxOptions'].binary = 'usr/bin/firefox';
// opts.capabilities.alwaysMatch['moz:firefoxOptions'].args = [];

// To initialize a Microsoft Edge session with GUI, uncomment the following lines:
// var opts = Browser.edgeOptions();
// opts.capabilities.alwaysMatch['ms:edgeOptions'].binary = 'usr/bin/microsoft-edge';
// opts.capabilities.alwaysMatch['ms:edgeOptions'].args = [];

var browser = new Browser(opts);

```

Note:

If your tests are running on a remote server or in a container, you can use a Virtual Network Computing (VNC) client to connect to the machine's VNC server. This lets you view and interact with the browser's GUI remotely.

Take screenshots

The following script:

1. Initializes a browser session.
2. Sets the browser's viewport size to determine the screenshot size (specified as parameters, see below).
3. Navigates to a URL (specified as a parameter, see below).
4. Collects session statistics, captures a screenshot, and adds it to the collected statistics.
5. Handles errors by capturing error messages and a screenshot.
6. Returns the collected results as a JSON string.

The script also uses parameters from the [item configuration form](#):

- webURL - http://example.com
- width - 1920
- height - 1080

In the *Script* field, enter:

```

var browser, result;

var browser = new Browser(Browser.chromeOptions());

try {
    var params = JSON.parse(value); // Parse the JSON string containing parameters passed from Zabbix.

    browser.setScreenSize(Number(params.width), Number(params.height))

    browser.navigate(params.webURL);

    result = browser.getResult();
    result.screenshot = browser.getScreenshot();
}
catch (err) {
    if (!(err instanceof BrowserError)) {
        browser.setError(err.message);
    }
    result = browser.getResult();
    result.error.screenshot = browser.getScreenshot();
}
finally {
    return JSON.stringify(result);
}

```

Check Zabbix login

The following script:

1. Initializes a browser session.
2. Navigates to a page (specified as a parameter, see below).
3. Enters the username and password (specified as parameters, see below).
4. Finds and clicks the login button.
5. Finds and clicks the logout button.
6. Collects performance data before and after login, as well as after logout.
7. Handles errors by capturing error messages and a screenshot.
8. Returns the collected results as a JSON string.

The script also uses parameters from the **item configuration form**:

- webURL - http://{HOST.CONN}/index.php
- username - {\$USERNAME}
- password - {\$PASSWORD}

In the *Script* field, enter:

```

var browser, result;

browser = new Browser(Browser.chromeOptions());

try {
    var params = JSON.parse(value); // Parse the JSON string containing parameters passed from Zabbix.

    browser.navigate(params.webURL);
    browser.collectPerfEntries("open page");

    var el = browser.findElement("xpath", "//*[@id='name']");
    if (el === null) {
        throw Error("cannot find name input field");
    }
    el.sendKeys(params.username);

    el = browser.findElement("xpath", "//*[@id='password']");
    if (el === null) {
        throw Error("cannot find password input field");
    }
}

```

```

el.sendKeys(params.password);

el = browser.findElement("xpath", "//button[@id='enter']");
if (el === null) {
    throw Error("cannot find login button");
}
el.click();

browser.collectPerfEntries("login");

el = browser.findElement("link text", "Sign out");
if (el === null) {
    throw Error("cannot find logout button");
}
el.click();

browser.collectPerfEntries("logout");

result = browser.getResult();
}
catch (err) {
    if (!(err instanceof BrowserError)) {
        browser.setError(err.message);
    }
    result = browser.getResult();
    result.error.screenshot = browser.getScreenshot();
}
finally {
    return JSON.stringify(result);
}

```

Find links

The following script:

1. Initializes a browser session.
2. Defines a function for removing duplicate elements from an array (see step 5).
3. Navigates to a page (specified as parameters, see below).
4. Finds links on the page.
5. Removes duplicate links to ensure they are unique.
6. Extracts only the links that start with "http".
7. Formats the extracted links to a specific structure.
8. Handles errors by capturing error messages and a screenshot.
9. Returns the collected results as a JSON string.

The script also uses parameters from the **item configuration form**:

- scheme - {\$WEBSITE.SCHEME}
- domain - {\$WEBSITE.DOMAIN}
- path - {\$WEBSITE.PATH}

In the *Script* field, enter:

```

var browser, result;

browser = new Browser(Browser.chromeOptions());

try {
    var params = JSON.parse(value); // Parse the JSON string containing parameters passed from Zabbix.

    function uniq(a) {
        return a.sort().filter(function (item, pos, ary) {
            return !pos || item !== ary[pos - 1];
        });
    }
}

```

```

browser.navigate(params.scheme + '://' + params.domain + params.path);

var el = browser.findElements("link text", "");
var links = [];
for (var n = 0; n < el.length; n++) {
    links.push(el[n].getAttribute('href'));
}

links = uniq(links);

result = [];
for (i = 0; i < links.length; i++) {
    if (links[i].match(/^http.*/)) {
        var row = {};
        row["{#URL}"] = links[i];
        result.push(row);
    }
}
}
catch (err) {
    if (!(err instanceof BrowserError)) {
        browser.setError(err.message);
    }
    result = browser.getResult();
    result.error.screenshot = browser.getScreenshot();
}
finally {
    return JSON.stringify(result);
}

```

4 History and trends

Overview

History and trends are the two ways of storing collected data in Zabbix.

Whereas history keeps each collected value, trends keep averaged information on hourly basis and therefore are less resource-hungry.

Keeping history

You can set for how many days history will be kept:

- in the item properties **form**
- when mass-updating items
- when **setting up** housekeeper tasks

Any older data will be removed by the housekeeper.

The general strong advice is to keep history for the smallest possible number of days and that way not to overload the database with lots of historical values.

Instead of keeping a long history, you can keep longer data of trends. For example, you could keep history for 14 days and trends for 5 years.

You can get a good idea of how much space is required by history versus trends data by referring to the [database sizing page](#).

While keeping shorter history, you will still be able to review older data in graphs, as graphs will use trend values for displaying older data.

Attention:

If history is set to '0', the item will update only dependent items and inventory. No trigger functions will be evaluated because trigger evaluation is based on history data only.

Note:

As an alternative way to preserve history consider to use **history export** functionality of loadable modules.

Keeping trends

Trends is a built-in historical data reduction mechanism which stores minimum, maximum, average and the total number of values per every hour for numeric data types.

You can set for how many days trends will be kept:

- in the item properties **form**
- when mass-updating items
- when setting up Housekeeper tasks

Trends usually can be kept for much longer than history. Any older data will be removed by the housekeeper.

Zabbix server accumulates trend data in runtime in the trend cache, as the data flows in. Server flushes **previous hour** trends of every item into the database (where frontend can find them) in these situations:

- server receives the first current hour value of the item
- 5 or less minutes of the current hour left and still no current hour values of the item
- server stops

To see trends on a graph you need to wait at least to the beginning of the next hour (if item is updated frequently) and at most to the end of the next hour (if item is updated rarely), which is 2 hours maximum.

When server flushes trend cache and there are already trends in the database for this hour (for example, server has been restarted mid-hour), server needs to use update statements instead of simple inserts. Therefore on a bigger installation if restart is needed it is desirable to stop server in the end of one hour and start in the beginning of the next hour to avoid trend data overlap.

History tables do not participate in trend generation in any way.

Attention:

If trends are set to '0', Zabbix server does not calculate or store trends at all.

Note:

The trends are calculated and stored with the same data type as the original values. As a result the average value calculations of unsigned data type values are rounded and the less the value interval is the less precise the result will be. For example if item has values 0 and 1, the average value will be 0, not 0.5. Also restarting server might result in the precision loss of unsigned data type average value calculations for the current hour.

5 User parameters

Overview

Sometimes you may want to run an agent check that does not come predefined with Zabbix. This is where user parameters come to help.

You may write a command that retrieves the data you need and include it in the user parameter in the **agent configuration file** ('UserParameter' configuration parameter).

A user parameter has the following syntax:

```
UserParameter=<key>,<command>
```

As you can see, a user parameter also contains a key. The key will be necessary when configuring an item. Enter a key of your choice that will be easy to reference (it must be unique within a host).

Restart the agent or use the agent **runtime control** option to pick up the new parameter, e. g.:

```
zabbix_agentd -R userparameter_reload
```

Then, when **configuring an item**, enter the key to reference the command from the user parameter you want executed.

User parameters are commands executed by Zabbix agent. Note that up to 16MB of data can be returned before **item value preprocessing** steps.

/bin/sh is used as a command line interpreter under UNIX operating systems. User parameters obey the agent check timeout; if timeout is reached the forked user parameter process is terminated.

See also:

- [Step-by-step tutorial](#) on making use of user parameters
- [Command execution](#)

Examples of simple user parameters

A simple command:

```
UserParameter=ping,echo 1
```

The agent will always return '1' for an item with 'ping' key.

A more complex example:

```
UserParameter=mysql.ping,mysqladmin -uroot ping | grep -c alive
```

The agent will return '1', if MySQL server is alive, '0' - otherwise.

Flexible user parameters

Flexible user parameters accept parameters with the key. This way a flexible user parameter can be the basis for creating several items.

Flexible user parameters have the following syntax:

```
UserParameter=key[*],command
```

| Parameter | Description |
|----------------|--|
| Key | Unique item key. The [*] defines that this key accepts parameters within the brackets. Parameters are given when configuring the item. |
| Command | Command to be executed to evaluate value of the key. <i>For flexible user parameters only:</i> You may use positional references \$1...\$9 in the command to refer to the respective parameter in the item key. Zabbix parses the parameters enclosed in [] of the item key and substitutes \$1,...,\$9 in the command accordingly. \$0 will be substituted by the original command (prior to expansion of \$0,...,\$9) to be run. Positional references are interpreted regardless of whether they are enclosed between double (") or single (') quotes. To use positional references unaltered, specify a double dollar sign - for example, awk '{print \$\$2}'. In this case \$\$2 will actually turn into \$2 when executing the command. |

Attention:

Positional references with the \$ sign are searched for and replaced by Zabbix agent only for flexible user parameters. For simple user parameters, such reference processing is skipped and, therefore, any \$ sign quoting is not necessary.

Attention:

Certain symbols are not allowed in user parameters by default. See [UnsafeUserParameters](#) documentation for a full list.

Example 1

Something very simple:

```
UserParameter=ping[*],echo $1
```

We may define unlimited number of items for monitoring all having format ping[something].

- ping[0] - will always return '0'
- ping[aaa] - will always return 'aaa'

Example 2

Let's add more sense!

```
UserParameter=mysql.ping[*],mysqladmin -u$1 -p$2 ping | grep -c alive
```

This parameter can be used for monitoring availability of MySQL database. We can pass user name and password:

```
mysql.ping[zabbix,our_password]
```

Example 3

How many lines matching a regular expression in a file?

```
UserParameter=wc[*],grep -c "$2" $1
```

This parameter can be used to calculate number of lines in a file.

```
wc[/etc/passwd,root]  
wc[/etc/services,zabbix]
```

Command result

The return value of the command is a standard output together with a standard error produced by the command.

Attention:

An item that returns text (character, log, or text type of information) will not become unsupported in case of a standard error output.

The return value is limited to 16MB (including trailing whitespace that is truncated); **database limits** also apply.

User parameters that return text (character, log, or text type of information) can also return a whitespace. In case of an invalid result, the item will become unsupported.

1 Extending Zabbix agents

This tutorial provides step-by-step instructions on how to extend the functionality of Zabbix agent with the use of a **user parameter**.

Step 1

Write a script or command line to retrieve required parameter.

For example, we may write the following command in order to get total number of queries executed by a MySQL server:

```
mysqladmin -uroot status | cut -f4 -d":" | cut -f1 -d"S"
```

When executed, the command returns total number of SQL queries.

Step 2

Add the command to zabbix_agentd.conf:

```
UserParameter=mysql.questions,mysqladmin -uroot status | cut -f4 -d":" | cut -f1 -d"S"
```

mysql.questions is a unique identifier. It can be any valid key identifier, for example, *queries*.

Test this parameter by using Zabbix agent with "-t" flag (if running under root, however, note that the agent may have different permissions when launched as a daemon):

```
zabbix_agentd -t mysql.questions
```

Step 3

Reload user parameters from the configuration file by running:

```
zabbix_agentd -R userparameter_reload
```

You may also restart the agent instead of the runtime control command.

Test the parameter by using **zabbix_get** utility.

Step 4

Add new item with Key=mysql.questions to the monitored host. Type of the item must be either Zabbix Agent or Zabbix Agent (active).

Be aware that type of returned values must be set correctly on Zabbix server. Otherwise Zabbix won't accept them.

6 Windows performance counters

Overview

You can effectively monitor Windows performance counters using the *perf_counter[]* key.

For example:

```
perf_counter["\Processor(0)\Interrupts/sec"]
```

or

```
perf_counter["\Processor(0)\Interrupts/sec", 10]
```

For more information on using this key or its English-only equivalent `perf_counter_en`, see [Windows-specific item keys](#).

In order to get a full list of performance counters available for monitoring, you may run:

```
typeperf -qx
```

You may also use low-level discovery to discover multiple [object instances](#) of Windows performance counters and automate the creation of `perf_counter` items for multiple instance objects.

Numeric representation

Windows maintains numeric representations (indexes) for object and performance counter names. Zabbix supports these numeric representations as parameters to the `perf_counter`, `perf_counter_en` item keys and in `PerfCounter`, `PerfCounterEn` configuration parameters.

However, it's not recommended to use them unless you can guarantee your numeric indexes map to correct strings on specific hosts. If you need to create portable items that work across different hosts with various localized Windows versions, you can use the `perf_counter_en` key or `PerfCounterEn` configuration parameter which allow to use English names regardless of system locale.

To find out the numeric equivalents, run **regedit**, then locate the *Counter* in `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib\009`.

The registry entry contains information like this:

```
1
1847
2
System
4
Memory
6
% Processor Time
10
File Read Operations/sec
12
File Write Operations/sec
14
File Control Operations/sec
16
File Read Bytes/sec
18
File Write Bytes/sec
....
```

Here you can find the corresponding numbers for each string part of the performance counter, like in '`\System\% Processor Time`':

```
System → 2
% Processor Time → 6
```

Then you can use these numbers to represent the path in numbers:

```
\2\6
```

Performance counter parameters

You can deploy some `PerfCounter` parameters for the monitoring of Windows performance counters.

For example, you can add these to the Zabbix agent configuration file:

```
PerfCounter=UserPerfCounter1,"\Memory\Page Reads/sec",30
or
PerfCounter=UserPerfCounter2,"\4\24",30
```

With such parameters in place, you can then simply use `UserPerfCounter1` or `UserPerfCounter2` as the keys for creating the respective items.

Remember to restart Zabbix agent after making changes to the configuration file.

7 Mass update

Overview

Sometimes you may want to change some attribute for a number of items at once. Instead of opening each individual item for editing, you may use the mass update function for that.

Using mass update

To mass-update some items, do the following:

- Mark the checkboxes of the items to update in the list
- Click on *Mass update* below the list
- Navigate to the tab with required attributes (*Item*, *Tags* or *Preprocessing*)
- Mark the checkboxes of the attributes to update
- Enter new values for the attributes

tag
value

Add

The *Tags* option allows to:

- *Add* - add specified tags to the items (tags with the same name, but different values are not considered 'duplicates' and can be added to the same item).
- *Replace* - remove the specified tags and add tags with new values
- *Remove* - remove specified tags from the items

User macros, {INVENTORY.*} macros, {HOST.HOST}, {HOST.NAME}, {HOST.CONN}, {HOST.DNS}, {HOST.IP}, {HOST.PORT} and {HOST.ID} macros are supported in tags.

output

Add

Mark the checkbox next to *Preprocessing steps* to activate mass update for preprocessing steps.

The *Preprocessing* mass update allows to:

- *Replace* - replace the existing preprocessing steps on the items with the preprocessing steps specified below
- *Remove all* - remove all preprocessing steps from the items

When done, click on *Update*.

8 Value mapping

Overview

Value mapping allows configuring a more user-friendly representation of received values using mappings between numeric/string values and string representations.

For example, when an item's value is "0" or "1," value mappings can be used to represent these values in a more user-friendly manner:

- 0 → Not Available
- 1 → Available

Value mappings for data backup types could be configured as follows:

- F → Full
- D → Differential
- I → Incremental

Value ranges for voltage could be configured as follows:

- <=209 → Low
- 210-230 → OK
- >=231 → High

Value mapping is used in Zabbix frontend and notifications sent by media types.

Attention:

Substitution of the received value with the configured representation is performed both in Zabbix frontend and server; however, the server handles substitution only in the following cases:

- when populating **host inventory**;
- when expanding **supported macros** {ITEM.VALUE}, {ITEM.LASTVALUE}, {EVENT.OPDATA}, and {EVENT.CAUSE.OPDATA}.

Value mappings are set up on templates or hosts. Once configured, they are available for all items within the respective template or host. When **configuring items**, specify the name of a previously configured value mapping in the *Value mapping* parameter.

Note:

There is no value map inheritance - hosts and templates do not inherit value mappings from linked templates. Template items on a host will continue to use the value mappings configured on the template.

Note:

Value mappings can be used with items having *Numeric (unsigned)*, *Numeric (float)*, and *Character* types of information.

Value mappings are exported/imported with the respective template or host. They can also be mass-updated using the **host** and **template** mass update forms.

Configuration

To configure a value mapping, follow these steps:

1. Open the host or template configuration form.
2. In the *Value mapping* tab, click *Add* to add a new value mapping, or click on the name of an existing mapping to edit it.

Value mapping

* Name

VMware status

* Mappings

| Type | Value | Mapped to |
|---|-------|-----------|
| <div>⋮</div> <div>equals</div> <div>▼</div> | 0 | ⇒ gray |
| <div>⋮</div> <div>equals</div> <div>▼</div> | 1 | ⇒ green |
| <div>⋮</div> <div>equals</div> <div>▼</div> | 2 | ⇒ yellow |
| <div>⋮</div> <div>equals</div> <div>▼</div> | 3 | ⇒ red |

Add

Update

Parameters of a value mapping:

| Parameter | Description |
|------------------|---|
| <i>Name</i> | Unique name for the set of value mappings. |
| <i>Mappings</i> | Individual rules for mapping numeric/string values to string representations. |
| <i>Type</i> | <p>Mapping is applied in the order of the rules that can be reordered by dragging.</p> <p>Mapping type:</p> <p>equals - equal values will be mapped;</p> <p>is greater than or equals - equal or greater values will be mapped;</p> <p>is less than or equals - equal or smaller values will be mapped;</p> <p>in range - values in range will be mapped; the range is expressed as <number1>-<number2> or <number>; multiple ranges are supported (for example, 1-10,101-110,201);</p> <p>regexp - values corresponding to the regular expression will be mapped (global regular expressions are not supported);</p> <p>default - all outstanding values will be mapped, other than those with specific mappings.</p> <p>For mapping ranges, only numeric value types (<i>is greater than or equals</i>, <i>is less than or equals</i>, <i>in range</i>) are supported.</p> |
| <i>Value</i> | Incoming value (may contain a range or regular expression, depending on the mapping type). |
| <i>Mapped to</i> | String representation (up to 64 characters) for the incoming value. |

All mandatory input fields are marked with a red asterisk.

When viewing the value mapping in the list, only the first three mappings are visible, with three dots indicating that more mappings exist.

[Template](#)
[Tags 2](#)
[Macros 6](#)
[Value mapping 1](#)

Value mapping

| Name | Value | Action |
|---------------------|-------------|------------------------|
| VMware status | =0 ⇒ gray | Remove |
| | =1 ⇒ green | |
| | =2 ⇒ yellow | |
| | ... | |
| Add | | |

Value mapping example

One of the predefined agent items *Zabbix agent ping* uses a template-level value mapping "Zabbix agent ping status" to display its values.

Value mapping

* Name

* Mappings

| Type | Value | Mapped to |
|--|--------------------------------|--|
| <div>⋮</div> <input type="text" value="equals"/> | <input type="text" value="1"/> | <div>⇒</div> <input type="text" value="Up"/> |

In the item **configuration form**, you can find a reference to this value mapping in the *Value mapping* field:

Value mapping

×

This mapping is used in the *Monitoring → Latest data* section to display "Up" (with the raw value in parentheses).

| ▼ <input type="checkbox"/> Host ▲ | Name | Last check | Last value |
|-----------------------------------|---------------------------|------------------------|------------|
| ▼ Zabbix server | Monitoring agent (1 item) | | |
| <input type="checkbox"/> | Zabbix agent ping ? | 02/23/2021 04:27:07 PM | Up (1) |

Note:

In the *Latest data* section, displayed values are shortened to 20 symbols. If value mapping is used, this shortening is not applied to the mapped value but only to the raw value (displayed in parentheses).

Without a predefined value mapping, you would only see "1", which might be challenging to understand.

| ▼ <input type="checkbox"/> Host ▲ | Name | Last check | Last value |
|-----------------------------------|---------------------------|------------------------|------------|
| ▼ Zabbix server | Monitoring agent (1 item) | | |
| <input type="checkbox"/> | Zabbix agent ping ? | 02/23/2021 06:00:07 PM | 1 |

9 Queue

Overview

The queue displays items that are waiting for a refresh. The queue is just a **logical** representation of data. There is no IPC queue or any other queue mechanism in Zabbix.

Items monitored by proxies are also included in the queue - they will be counted as queued for the proxy history data update period.

Only items with scheduled refresh times are displayed in the queue. This means that the following item types are excluded from the queue:

- log, logrt and event log active Zabbix agent items
- SNMP trap items
- trapper items
- web monitoring items
- dependent items

Statistics shown by the queue is a good indicator of the performance of Zabbix server.

The queue is retrieved directly from Zabbix server using JSON protocol. The information is available only if Zabbix server is running.

Attention:

Items are not counted in the queue if the item interface becomes unavailable due to connection problems or agent not working properly.

Reading the queue

To read the queue, go to *Administration* → *Queue*.

| Queue overview ▼ | | | | | | |
|-----------------------|-----------|------------|------------|----------|-----------|----------------------|
| Items | 5 seconds | 10 seconds | 30 seconds | 1 minute | 5 minutes | More than 10 minutes |
| Zabbix agent | 1 | 11 | 1 | 0 | 0 | 0 |
| Zabbix agent (active) | 0 | 0 | 0 | 0 | 0 | 0 |
| Simple check | 0 | 0 | 0 | 0 | 0 | 0 |
| SNMPv1 agent | 0 | 0 | 0 | 0 | 0 | 0 |
| SNMPv2 agent | 0 | 0 | 0 | 0 | 0 | 0 |
| SNMPv3 agent | 0 | 0 | 0 | 0 | 0 | 0 |
| Zabbix internal | 0 | 0 | 0 | 0 | 0 | 0 |
| Zabbix aggregate | 0 | 0 | 0 | 0 | 0 | 0 |
| External check | 0 | 0 | 0 | 0 | 0 | 0 |
| Database monitor | 0 | 0 | 0 | 0 | 0 | 0 |
| HTTP agent | 0 | 0 | 0 | 0 | 0 | 0 |

The picture here is generally "ok" so we may assume that the server is doing fine.

The queue shows some items waiting up to 30 seconds. It would be great to know what items these are. To do just that, select *Queue details* in the title dropdown. Now you can see a list of those delayed items.

☰ Queue details ▾

| Scheduled check | Delayed by | Host | Name | Proxy |
|---------------------|------------|---------|--------------------|--------------|
| 2019-09-02 11:46:40 | 58s | My host | CPU idle time | Remote proxy |
| 2019-09-02 11:46:41 | 57s | My host | CPU interrupt time | Remote proxy |
| 2019-09-02 11:46:42 | 56s | My host | CPU iowait time | Remote proxy |
| 2019-09-02 11:46:43 | 55s | My host | CPU nice time | Remote proxy |
| 2019-09-02 11:46:44 | 54s | My host | CPU softirq time | Remote proxy |
| 2019-09-02 11:46:45 | 53s | My host | CPU steal time | Remote proxy |
| 2019-09-02 11:46:46 | 52s | My host | CPU system time | Remote proxy |

With these details provided it may be possible to find out why these items might be delayed. With one or two delayed items there perhaps is no cause for alarm. They might get updated in a second. However, if you see a bunch of items getting delayed for too long, there might be a more serious problem.

See also: Aligning time zones when using [scheduling intervals](#).

☰ Queue overview ▾

| Items | 5 seconds | 10 seconds | 30 seconds | 1 minute | 5 minutes | More than 10 minutes |
|-----------------------|-----------|------------|------------|----------|-----------|----------------------|

| SSH agent | 0 | 0 | 0 | 0 | 0 | 0 |
| TELNET agent | 0 | 0 | 0 | 0 | 0 | 0 |
| JMX agent | 0 | 0 | 0 | 0 | 0 | 0 |
| Calculated | 0 | 0 | 0 | 0 | 0 | 0 |

Queue item

A special internal item **zabbix[queue,<from>,<to>]** can be used to monitor the health of the queue in Zabbix. It will return the number of items delayed by the set amount of time. For more information see [Internal items](#).

10 Value cache

Overview

To make the calculation of trigger expressions, calculated items and some macros much faster, a value cache option is supported by the Zabbix server.

This in-memory cache can be used for accessing historical data, instead of making direct SQL calls to the database. If historical values are not present in the cache, the missing values are requested from the database and the cache updated accordingly.

Item values remain in value cache either until:

- the item is deleted (cached values are deleted after the next configuration sync);
- the item value is outside the time or count range specified in the trigger/calculated item expression (cached value is removed when a new value is received);
- the time or count range specified in the trigger/calculated item expression is changed so that less data is required for calculation (unnecessary cached values are removed after 24 hours).

Note:

Value cache status can be observed by using the server **runtime control** option `diaginfo` (or `diaginfo=valuecache`) and inspecting the section for value cache diagnostic information. This can be useful for determining misconfigured triggers or calculated items.

To enable the value cache functionality, an optional **ValueCacheSize** parameter is supported by the Zabbix server **configuration** file.

Two internal items are supported for monitoring the value cache: **zabbix[valuecache,buffer,<mode>]** and **zabbix[valuecache,cache,<parameter>]**. See more details with **internal items**.

11 Execute now

Overview

Checking for a new item value in Zabbix is a cyclic process that is based on configured update intervals. While for many items the update intervals are quite short, there are others (including low-level discovery rules) for which the update intervals are quite long, so in real-life situations there may be a need to check for a new value quicker - to pick up changes in discoverable resources, for example. To accommodate such a necessity, it is possible to reschedule a passive check and retrieve a new value immediately.

This functionality is supported for **passive** checks only. The following item types are supported:

- Zabbix agent (passive)
- SNMPv1/v2/v3 agent
- IPMI agent
- Simple check
- Zabbix internal
- External check
- Database monitor
- JMX agent
- SSH agent
- Telnet
- Calculated
- HTTP agent
- Dependent item
- Script

Attention:

The check must be present in the configuration cache in order to get executed; for more information see **CacheUpdateFrequency**. Before executing the check, the configuration cache is **not** updated, thus very recent changes to item/discovery rule configuration will not be picked up. Therefore, it is also not possible to check for a new value for an item/rule that is being created or has been created just now; use the *Test* option while configuring an item for that.

Configuration

To execute a passive check immediately:

- click on *Execute now* for selected items in the list of latest data:

Latest data

The screenshot shows the 'Latest data' interface with tabs for Memory, CPU, Server, and Web checks. A subfilter 'General 2' is applied. The table lists two hosts: 'Zabbix server' and 'Zabbix server', both with metrics 'Maximum number of open file descriptors' and 'Maximum number of processes'. The 'Execute now' button is highlighted with a green arrow.

| Host | Name | Last check |
|---------------|---|------------|
| Zabbix server | Maximum number of open file descriptors | 51m 54s |
| Zabbix server | Maximum number of processes | 51m 53s |

Several items can be selected and "executed now" at once.

In latest data this option is available only for hosts with read-write access. Accessing this option for hosts with read-only permissions depends on the **user role** option called *Invoke "Execute now" on read-only hosts*.

- click on *Execute now* in an existing item (or discovery rule) configuration form:

The screenshot shows the configuration form for an item. The 'Enabled' checkbox is checked. The 'Execute now' button is highlighted with a green arrow.

- click on *Execute now* for selected items/rules in the list of items/discovery rules:

The screenshot shows the list of items/discovery rules. The 'Execute now' button is highlighted with a green arrow.

| Item/Rule |
|---|
| Template Module Linux network interfaces by Zabbix agent: Network interface discovery |

Several items/rules can be selected and "executed now" at once.

12 Restricting agent checks

Overview

It is possible to restrict checks on the agent side by creating an item blacklist, a whitelist, or a combination of whitelist/blacklist.

To do that use a combination of two agent **configuration** parameters:

- AllowKey=<pattern> - which checks are allowed; <pattern> is specified using a wildcard (*) expression
- DenyKey=<pattern> - which checks are denied; <pattern> is specified using a wildcard (*) expression

Note that:

- All system.run[*] items (remote commands, scripts) are disabled by default, even when no deny keys are specified, it should be assumed that DenyKey=system.run[*] is implicitly appended.
- Since Zabbix 5.0.2 the EnableRemoteCommands agent parameter is:
 - deprecated by Zabbix agent
 - unsupported by Zabbix agent2

Therefore, to allow remote commands, specify an AllowKey=system.run[<command>,*] for each allowed command, * stands for wait and nowait mode. It is also possible to specify AllowKey=system.run[*] parameter to allow all commands with wait and nowait modes. To disallow specific remote commands, add DenyKey parameters with system.run[] commands before the AllowKey=system.run[*] parameter.

Important rules

- A whitelist without a deny rule is only allowed for system.run[*] items. For all other items, AllowKey parameters are not allowed without a DenyKey parameter; in this case Zabbix agent **will not start** with only AllowKey parameters.
- The order matters. The specified parameters are checked one by one according to their appearance order in the configuration file:
 - As soon as an item key matches an allow/deny rule, the item is either allowed or denied; and rule checking stops. So if an item matches both an allow rule and a deny rule, the result will depend on which rule comes first.
 - The order affects also EnableRemoteCommands parameter (if used).
- Unlimited numbers of AllowKey/DenyKey parameters is supported.
- AllowKey, DenyKey rules do not affect HostnameItem, HostMetadataItem, HostInterfaceItem configuration parameters.
- Key pattern is a wildcard expression where the wildcard (*) character matches any number of any characters in certain position. It might be used in both the key name and parameters.
- If a specific item key is disallowed in the agent configuration, the item will be reported as unsupported (no hint is given as to the reason);
- Zabbix agent with --print (-p) command line option will not show keys that are not allowed by configuration;
- Zabbix agent with --test (-t) command line option will return "Unsupported item key." status for keys that are not allowed by configuration;
- Denied remote commands will not be logged in the agent log (if LogRemoteCommands=1).

Use cases

Deny specific check

- Blacklist a specific check with DenyKey parameter. Matching keys will be disallowed. All non-matching keys will be allowed, except system.run[] items.

For example:

```
# Deny secure data access
DenyKey=vfs.file.contents[/etc/passwd,*]
```

Attention:

A blacklist may not be a good choice, because a new Zabbix version may have new keys that are not explicitly restricted by the existing configuration. This could cause a security flaw.

Deny specific command, allow others

- Blacklist a specific command with DenyKey parameter. Whitelist all other commands, with the AllowKey parameter.

```
# Disallow specific command
DenyKey=system.run[ls -l /]
```

```
# Allow other scripts
AllowKey=system.run[*]
```

Allow specific check, deny others

- Whitelist specific checks with AllowKey parameters, deny others with DenyKey=*

For example:

```
# Allow reading logs:
AllowKey=vfs.file.*[/var/log/*]
```

```
# Allow localtime checks
AllowKey=system.localtime[*]
```

```
# Deny all other keys
DenyKey=*
```

Allow script with spaces in path and arguments

- Whitelist a script located in a path that contains spaces and allow passing arguments to it. On Windows, escape spaces using ^ when specifying the path.

For example:

```
# Allow running test.bat with or without arguments
AllowKey=system.run["C:\Program^ Files\Zabbix^ Agent^ 2\scripts\test.bat*"]
```

To test:

```
PS C:\Program Files\Zabbix Agent 2> .\zabbix_get.exe -s 127.0.0.1 -k system.run["C:\Program^ Files\Zabbix^ Agent^ 2\scripts\test.bat"]
```

This configuration allows execution of the script regardless of whether arguments are passed (such as caret) and ensures that `system.run` is permitted even if the script path contains spaces.

Pattern examples

| Pattern | Description | Matches | No match |
|--|---|---|---|
| * | Matches all possible keys with or without parameters. | Any | None |
| <i>vfs.file.contents</i> | Matches <i>vfs.file.contents</i> without parameters. | <i>vfs.file.contents</i> | <i>vfs.file.contents[/etc/passwd]</i> |
| <i>vfs.file.contents[]</i> | Matches <i>vfs.file.contents</i> with empty parameters. | <i>vfs.file.contents[]</i> | <i>vfs.file.contents</i> |
| <i>vfs.file.contents[*]</i> | Matches <i>vfs.file.contents</i> with any parameters; will not match <i>vfs.file.contents</i> without square brackets. | <i>vfs.file.contents[]</i> <i>vfs.file.contents[/path/to/file]</i> | <i>vfs.file.contents</i> |
| <i>vfs.file.contents[/etc/passwd]</i> | Matches <i>vfs.file.contents</i> with first parameters matching <i>/etc/passwd</i> and all other parameters having any value (also empty). | <i>vfs.file.contents[/etc/passwd]</i> <i>vfs.file.contents[/etc/passwd,utf8]</i> | <i>vfs.file.contents[/etc/passwd]</i> <i>vfs.file.contents[/var/log/zabbix_server.log]</i> <i>vfs.file.contents[]</i> |
| <i>vfs.file.contents[*passwd]</i> | Matches <i>vfs.file.contents</i> with first parameter matching <i>*passwd*</i> and no other parameters. | <i>vfs.file.contents[/etc/passwd]</i> | <i>vfs.file.contents[/etc/passwd,utf8]</i> |
| <i>vfs.file.contents[*passwd*]</i> | Matches <i>vfs.file.contents</i> with only first parameter matching <i>*passwd*</i> and all following parameters having any value (also empty). | <i>vfs.file.contents[/etc/passwd]</i> <i>vfs.file.contents[/etc/passwd,tmp/test]</i> <i>utf8]</i> | <i>vfs.file.contents[/etc/passwd]</i> |
| <i>vfs.file.contents[/var/log/zabbix_server.log,abc]</i> | Matches <i>vfs.file.contents</i> with first parameter matching <i>/var/log/zabbix_server.log</i> , third parameter matching <i>'abc'</i> and any (also empty) second parameter. | <i>vfs.file.contents[/var/log/zabbix_server.log,log,zabbix_server.log]</i> <i>vfs.file.contents[/var/log/zabbix_server.log,utf8,abc]</i> | |
| <i>vfs.file.contents[/etc/passwd,utf8]</i> | Matches <i>vfs.file.contents</i> with first parameter matching <i>/etc/passwd</i> , second parameter matching <i>'utf8'</i> and no other arguments. | <i>vfs.file.contents[/etc/passwd,utf8]</i> | <i>vfs.file.contents[/etc/passwd]</i> <i>vfs.file.contents[/etc/passwd,utf1]</i> |
| <i>vfs.file.*</i> | Matches any keys starting with <i>vfs.file.</i> without any parameters. | <i>vfs.file.contents</i> <i>vfs.file.size</i> | <i>vfs.file.contents[]</i> <i>vfs.file.size[/var/log/zabbix_server.log]</i> |
| <i>vfs.file.*[*]</i> | Matches any keys starting with <i>vfs.file.</i> with any parameters. | <i>vfs.file.size.bytes[]</i> <i>vfs.file.size[/var/log/zabbix_server.log,utf8]</i> | <i>vfs.file.size.bytes</i> |
| <i>vfs.*.contents</i> | Matches any key starting with <i>vfs.</i> and ending with <i>.contents</i> without any parameters. | <i>vfs.mount.point.file.contents</i> <i>vfs..contents</i> | <i>vfs.file.contents</i> |

`system.run` and `AllowKey`

A hypothetical script like `'myscript.sh'` may be executed on a host via Zabbix agent in several ways:

1. As an item key in a passive or active check, for example:

- `system.run[myscript.sh]`
- `system.run[myscript.sh,wait]`
- `system.run[myscript.sh,nowait]`

Here the user may add "wait", "nowait" or omit the 2nd argument to use its default value in `system.run[]`.

2. As a global script (initiated by user in frontend or API).

A user configures this script in *Alerts* → *Scripts*, sets "Execute on: Zabbix agent" and puts "myscript.sh" into the script's "Commands" input field. When invoked from frontend or API the Zabbix server sends to agent:

- `system.run[myscript.sh,wait]` - up to Zabbix 5.0.4
- `system.run[myscript.sh]` - since 5.0.5

Here the user does not control the "wait"/"nowait" parameters.

3. As a remote command from an action. The Zabbix server sends to agent:

- `system.run[myscript.sh,nowait]`

Here again the user does not control the "wait"/"nowait" parameters.

What that means is if we set `AllowKey` like:

`AllowKey=system.run[myscript.sh]`

then

- `system.run[myscript.sh]` - will be allowed
- `system.run[myscript.sh,wait]`, `system.run[myscript.sh,nowait]` will not be allowed - the script will not be run if invoked as a step of action

To allow all described variants you may add:

`AllowKey=system.run[myscript.sh,*]`

`DenyKey=system.run[*]`

to the `agent/agent2` parameters.

3 Triggers

Overview

Triggers are logical expressions that "evaluate" data gathered by items and represent the current system state.

While items are used to gather system data, it is highly impractical to follow these data all the time waiting for a condition that is alarming or deserves attention. The job of "evaluating" data can be left to trigger expressions.

Trigger expressions allow to define a threshold of what state of data is "acceptable". Therefore, should the incoming data surpass the acceptable state, a trigger is "fired" - or changes its status to **PROBLEM**.

A trigger may have the following status:

| Status | Description |
|---------|--|
| OK | This is a normal trigger status. |
| Problem | Something has happened. For example, the processor load is too high. |
| Unknown | The trigger value cannot be calculated. See Unknown status . |

In a simple trigger we may want to set a threshold for a five-minute average of some data, for example, the CPU load. This is accomplished by defining a trigger expression where:

- the 'avg' function is applied to the value received in the item key
- a five minute period for evaluation is used
- a threshold of '2' is set

`avg(/host/key,5m)>2`

This trigger will "fire" (become **PROBLEM**) if the five-minute average is over 2.

In a more complex trigger, the expression may include a **combination** of multiple functions and multiple thresholds. See also: [Trigger expression](#).

Triggers cannot be created for items with binary values.

Note:

After enabling a trigger (changing its configuration status from *Disabled* to *Enabled*), the trigger expression is evaluated as soon as an item in it receives a value or the time to handle **date and time** and/or **nodata()** functions comes.

Most trigger functions are evaluated based on item value **history** data, while some trigger functions for long-term analytics, e.g. **trendavg()**, **trendcount()**, etc, use trend data.

Calculation time

A trigger is recalculated every time Zabbix server receives a new value that is part of the expression. When a new value is received, each function that is included in the expression is recalculated (not just the one that received the new value).

Additionally, a trigger is recalculated each time when a new value is received **and** every 30 seconds if **date and time** and/or **nodata()** functions are used in the expression.

Date and time and/or **nodata()** functions are recalculated every 30 seconds by the Zabbix history syncer process.

Triggers that reference trend functions **only** are evaluated once per the smallest time period in the expression. See also **trend functions**.

Evaluation period

An evaluation period is used in functions referencing the item history. It allows to specify the interval we are interested in. It can be specified as time period (30s, 10m, 1h) or as a value range (#5 - for five latest values).

The evaluation period is measured up to "now" - where "now" is the latest recalculation time of the trigger (see **Calculation time** above); "now" is not the "now" time of the server.

The evaluation period specifies either:

- To consider all values between "now-time period" and "now" (or, with time shift, between "now-time shift-time period" and "now-time_shift")
- To consider no more than the num count of values from the past, up to "now"
 - If there are 0 available values for the time period or num count specified - then the trigger or calculated item that uses this function becomes unsupported

Note that:

- If only a single function (referencing data history) is used in the trigger, "now" is always the latest received value. For example, if the last value was received an hour ago, the evaluation period will be regarded as up to the latest value an hour ago.
- A new trigger is calculated as soon as the first value is received (history functions); it will be calculated within 30 seconds for **date and time** and **nodata()** functions. Thus the trigger will be calculated even though perhaps the set evaluation period (for example, one hour) has not yet passed since the trigger was created. The trigger will also be calculated after the first value, even though the evaluation range was set, for example, to ten latest values.

Unknown status

It is possible that an unknown operand appears in a trigger expression if:

- an unsupported item is used
- the function evaluation for a supported item results in an error

In this case a trigger generally evaluates to "unknown" (although there are some exceptions). For more details, see **Expressions with unknown operands**.

It is possible to **get notified** on unknown triggers.

1 Configuring a trigger

Overview

To configure a trigger, do the following:

- Go to: *Data collection* → *Hosts*
- Click on *Triggers* in the row of the host
- Click on *Create trigger* to the right (or on the trigger name to edit an existing trigger)
- Enter parameters of the trigger in the form

See also **general information** on triggers and their calculation times.

Configuration

The **Trigger** tab contains all the essential trigger attributes.

New trigger

Trigger Tags Dependencies

* Name: High CPU utilization (over {SCPU.UTIL.CRIT}% for 5m)

Event name: High CPU utilization (over {SCPU.UTIL.CRIT}% for 5m)

Operational data: Current utilization: {ITEM.LASTVALUE1}

Severity: Not classified Information **Warning** Average High Disaster

* Expression: min(/New host/system.cpu.util,5m)>{SCPU.UTIL.CRIT} Add

Expression constructor

OK event generation: Expression Recovery expression None

PROBLEM event generation mode: Single Multiple

OK event closes: All problems All problems if tag values match

* Tag for matching:

Allow manual close: ☐

Menu entry name: Trigger URL

Menu entry URL:

Description: CPU utilization is too high. The system might be slow to respond.

Enabled: ☒

Add Cancel

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|-------------------------|--|
| <i>Name</i> | <p>Trigger name.</p> <p>Supported macros are: {HOST.HOST}, {HOST.NAME}, {HOST.PORT}, {HOST.CONN}, {HOST.DNS}, {HOST.IP}, {HOST.PORT}, {ITEM.VALUE}, {ITEM.LASTVALUE}, {ITEM.LOG.*} and {MACRO} user macros.</p> <p>\$1, \$2...\$9 macros can be used to refer to the first, second...ninth constant of the expression.</p> <p><i>Note:</i> \$1-\$9 macros will resolve correctly if referring to constants in relatively simple, straightforward expressions. For example, the name "Processor load above \$1 on {HOST.NAME}" will automatically change to "Processor load above 5 on New host" if the expression is last(/New host/system.cpu.load[percpu,avg1])>5</p> |
| <i>Event name</i> | <p>If defined, this name will be used to create the problem event name, instead of the trigger name. The event name may be used to build meaningful alerts containing problem data (see example). The same set of macros is supported as in the trigger name, plus {TIME}, {TIMESTAMP}, and {?EXPRESSION} expression macros.</p> |
| <i>Operational data</i> | <p>Operational data allow to define arbitrary strings along with macros. The macros will resolve dynamically to real time data in <i>Monitoring</i> → <i>Problems</i>. While macros in the trigger name (see above) will resolve to their values at the moment of a problem happening and will become the basis of a static problem name, the macros in the operational data maintain the ability to display the very latest information dynamically. If no operational data is configured on a trigger level, the latest values of all items from the expression will be displayed.</p> <p>The same set of macros is supported as in the trigger name.</p> |
| <i>Severity</i> | <p>Set the required trigger severity by clicking the buttons.</p> |
| <i>Expression</i> | <p>Logical expression used to define the conditions of a problem.</p> <p>Time suffixes and memory size suffixes are supported.</p> <p>A problem is created after all the conditions included in the expression are met, i.e. the expression evaluates to TRUE. The problem will be resolved as soon as the expression evaluates to FALSE, unless additional recovery conditions are specified in <i>Recovery expression</i>.</p> |

| Parameter | Description |
|--------------------------------------|--|
| <i>OK event generation</i> | OK event generation options: Expression - OK events are generated based on the same expression as problem events; Recovery expression - OK events are generated if the problem expression evaluates to FALSE and the recovery expression evaluates to TRUE; None - in this case the trigger will never return to an OK state on its own. |
| <i>Recovery expression</i> | Logical expression (optional) defining additional conditions that have to be met before the problem is resolved, after the original problem expression has already been evaluated as FALSE. Recovery expression is useful for trigger hysteresis . It is not possible to resolve a problem by recovery expression alone if the problem expression is still TRUE. This field is only available if 'Recovery expression' is selected for <i>OK event generation</i> . |
| <i>PROBLEM event generation mode</i> | Mode for generating problem events: Single - a single event is generated when a trigger goes into the 'Problem' state for the first time; Multiple - an event is generated upon every 'Problem' evaluation of the trigger. |
| <i>OK event closes</i> | Select if OK event closes: All problems - all problems of this trigger All problems if tag values match - only those trigger problems with matching event tag values |
| <i>Tag for matching</i> | Enter event tag name to use for event correlation. This field is displayed if 'All problems if tag values match' is selected for the <i>OK event closes</i> property and is mandatory in this case. |
| <i>Allow manual close</i> | Check to allow manual closing of problem events generated by this trigger. Manual closing is possible when acknowledging problem events. |
| <i>Menu entry name</i> | If not empty, the name entered here (up to 64 characters) is used in several frontend locations as a label for the trigger URL specified in the <i>Menu entry URL</i> parameter. If empty, the default name <i>Trigger URL</i> is used. |
| <i>Menu entry URL</i> | The same set of macros is supported as in the trigger URL. If not empty, the URL entered here (up to 2048 characters) is available as a link in the event menu in several frontend locations, for example, when clicking on the problem name in <i>Monitoring</i> → <i>Problems</i> or <i>Problems</i> dashboard widget. The same set of macros is supported as in the trigger name, plus {EVENT.ID}, {HOST.ID} and {TRIGGER.ID}. Note: user macros with secret values will not be resolved in the URL. |
| <i>Description</i> | Text field used to provide more information about this trigger. May contain instructions for fixing specific problem, contact detail of responsible staff, etc. |
| <i>Enabled</i> | The same set of macros is supported as in the trigger name. Unchecking this box will disable the trigger if required. Problems of a disabled trigger are no longer displayed in the frontend, but are not deleted. |

The **Tags** tab allows you to define trigger-level **tags**. All problems of this trigger will be tagged with the values entered here.

In addition the *Inherited and trigger tags* option allows to view tags defined on template level, if the trigger comes from that template. If there are multiple templates with the same tag, these tags are displayed once and template names are separated with commas. A trigger does not "inherit" and display host-level tags.

| Parameter | Description |
|-------------------|---|
| <i>Name/Value</i> | <p>Set custom tags to mark trigger events.</p> <p>Tags are a pair of tag name and value. You can use only the name or pair it with a value. A trigger may have several tags with the same name, but different values.</p> <p>User macros, user macros with context, low-level discovery macros and macro functions with <code>{{ITEM.VALUE}}</code>, <code>{{ITEM.LASTVALUE}}</code> and low-level discovery macros are supported in event tags. Low-level discovery macros can be used inside macro context.</p> <p><code>{TRIGGER.ID}</code> macro is supported in trigger tag values. It may be useful for identifying triggers created from trigger prototypes and, for example, suppressing problems from these triggers during maintenance.</p> <p>If the total length of expanded value exceeds 255, it will be cut to 255 characters.</p> <p>See all macros supported for event tags.</p> <p>Event tags can be used for event correlation, in action conditions and will also be seen in <i>Monitoring → Problems</i> or the <i>Problems</i> widget.</p> |

The **Dependencies** tab contains all the **dependencies** of the trigger.

Click on *Add* to add a new dependency.

Note:

You can also configure a trigger by opening an existing one, pressing the *Clone* button and then saving under a different name.

Testing expressions

It is possible to test the configured trigger expression as to what the expression result would be depending on the received value.

The following expression from an official template is taken as an example:

```
avg(/Cisco IOS SNMPv2/sensor.temp.value[ciscoEnvMonTemperatureValue.{#SNMPINDEX}],5m)>{$TEMP_WARN}
or
last(/Cisco IOS SNMPv2/sensor.temp.status[ciscoEnvMonTemperatureState.{#SNMPINDEX}])={$TEMP_WARN_STATUS}
```

To test the expression, click on *Expression constructor* under the expression field.

The screenshot shows the 'Trigger' configuration window with the following details:

- Name:** Cisco IOS SNMPv2: Temperature is too high
- Event name:** Cisco IOS SNMPv2: Temperature is too high
- Operational data:** (empty field)
- Severity:** Not classified, Information, **Warning**, Average, High, Disaster
- Expression:**

```
avg(/Cisco IOS
SNMPv2/sensor.temp.value[ciscoEnvMonTemperature
Value.{#SNMPINDEX}],5m)>{$TEMP_WARN}
or
last(/Cisco IOS
SNMPv2/sensor.temp.status[ciscoEnvMonTemperatur
eState.{#SNMPINDEX}])={$TEMP_WARN_STATUS}
```
- Expression constructor:** A link below the expression field, highlighted with a green arrow.

In the Expression constructor, all individual expressions are listed. To open the testing window, click on *Test* below the expression list.

Target Expression

☒ Or

☐ A avg(/Cisco IOS SNMPv2/sensor.temp.value[ciscoEnvMonTemperatureValue.{#SNMPINDEX}],5m)>{\$TEMP_WARN}

☐ B last(/Cisco IOS SNMPv2/sensor.temp.status[ciscoEnvMonTemperatureState.{#SNMPINDEX}])={\$TEMP_WARN_STATUS}

[Test](#) 

In the testing window you can enter sample values ('80', '70', '0', '1' in this example) and then see the expression result, by clicking on the **Test** button.

Test

Test data

| Expression Variable Elements | Result type | Value |
|---|-------------------|---------------------------------|
| avg(/Cisco IOS SNMPv2/sensor.temp.value[ciscoEnvMonTemperatureValue.{#SNMPINDEX}],5m) | Numeric (float) | <input type="text" value="80"/> |
| {\$TEMP_WARN} | Any | <input type="text" value="70"/> |
| last(/Cisco IOS SNMPv2/sensor.temp.status[ciscoEnvMonTemperatureState.{#SNMPINDEX}]) | Numeric (integer) | <input type="text" value="0"/> |
| {\$TEMP_WARN_STATUS} | Any | <input type="text" value="1"/> |

Result

| Expression | Result | Error |
|---|--------|-------|
| Or | TRUE | |
| A avg(/Cisco IOS SNMPv2/sensor.temp.value[ciscoEnvMonTemperatureValue.{#SNMPINDEX}],5m)>{\$TEMP_WARN} | TRUE | |
| B last(/Cisco IOS SNMPv2/sensor.temp.status[ciscoEnvMonTemperatureState.{#SNMPINDEX}])={\$TEMP_WARN_STATUS} | FALSE | |
| A or B | TRUE | |

Test

Cancel

The result of the individual expressions as well as the whole expression can be seen.

"TRUE" means that the specified expression is correct. In this particular case A, "80" is greater than the {\$TEMP_WARN} specified value, "70" in this example. As expected, a "TRUE" result appears.

"FALSE" means that the specified expression is incorrect. In this particular case B, {\$TEMP_WARN_STATUS} "1" needs to be equal with specified value, "0" in this example. As expected, a "FALSE" result appears.

The chosen expression type is "OR". If at least one of the specified conditions (A or B in this case) is TRUE, the overall result will be TRUE as well. Meaning that the current value exceeds the warning value and a problem has occurred.

2 Trigger expression

Overview

The expressions used in **triggers** are very flexible. You can use them to create complex logical tests regarding monitored statistics.

A simple expression uses a **function** that is applied to the item with some parameters. The function returns a result that is compared to the threshold, using an operator and a constant.

The syntax of a simple useful expression is `function(/host/key,parameter)<operator><constant>`.

For example:

```
min(/Zabbix server/net.if.in[eth0,bytes],5m)>100K
```

will trigger if the number of received bytes during the last five minutes was always over 100 kilobytes.

While the syntax is exactly the same, from the functional point of view there are two types of trigger expressions:

- problem expression - defines the conditions of the problem
- recovery expression (optional) - defines additional conditions of the problem resolution

When defining a problem expression alone, this expression will be used both as the problem threshold and the problem recovery threshold. As soon as the problem expression evaluates to TRUE, there is a problem. As soon as the problem expression evaluates to FALSE, the problem is resolved.

When defining both problem expression and the supplemental recovery expression, problem resolution becomes more complex: not only the problem expression has to be FALSE, but also the recovery expression has to be TRUE. This is useful to create **hysteresis** and avoid trigger flapping.

Note:

It is unproductive to use the {TRIGGER.VALUE} macro in a recovery expression because this expression is only evaluated when the trigger is in the "Problem" state. Consequently, {TRIGGER.VALUE} will always resolve to "1" (which indicates a "Problem" state) while evaluating the expression.

Functions

Functions allow to calculate the collected values (average, minimum, maximum, sum), find strings, reference current time and other factors.

A complete list of **supported functions** is available.

Typically functions return numeric values for comparison. When returning strings, comparison is possible with the = and <> operators (see **example**).

Function parameters

Function parameters allow to specify:

- host and item key (functions referencing the host item history only)
- function-specific parameters
- other expressions (not available for functions referencing the host item history, see **other expressions** for examples)

The host and item key can be specified as /host/key.

If a host is omitted (i.e. as in function(/key,parameter,...)), the function will reference the current host.

The referenced item must be in a supported state (except for **nodata()** function, which is calculated for unsupported items as well).

While other trigger expressions as function parameters are limited to non-history functions in triggers, this limitation does not apply in **calculated items**.

Function-specific parameters

Function-specific parameters are placed after the item key and are separated from the item key by a comma. See the **supported functions** for a complete list of these parameters.

Most of numeric functions accept time as a parameter. You may use seconds or **time suffixes** to indicate time. Preceded by a hash mark, the parameter has a different meaning:

| Expression | Description |
|---------------------------|---------------------------------------|
| sum(/host/key,10m) | Sum of values in the last 10 minutes. |
| sum(/host/key,#10) | Sum of the last ten values. |

Parameters with a hash mark have a different meaning with the function **last** - they denote the Nth previous value, so given the values 30, 70, 20, 60, 50 (from the most recent to the least recent):

- last(/host/key,#2) would return '70'
- last(/host/key,#5) would return '50'

Time shift

An optional time shift is supported with time or value count as the function parameter. This parameter allows to reference data from a period of time in the past.

Time shift starts with now - specifying the current time, and is followed by +N<time unit> or -N<time unit> - to add or subtract N time units.

For example, avg(/host/key,1h:now-1d) will return the average value for an hour one day ago.

Attention:

Time shift specified in months (M) and years (y) is only supported for **trend functions**. Other functions support seconds (s), minutes (m), hours (h), days (d), and weeks (w).

Time shift with absolute time periods

Absolute time periods are supported in the time shift parameter, for example, midnight to midnight for a day, Monday-Sunday for a week, first day-last day of the month for a month.

Time shift for absolute time periods starts with `now` - specifying the current time, and is followed by any number of time operations: `/<time unit>` - defines the beginning and end of the time unit, for example, midnight to midnight for a day, `+N<time unit>` or `-N<time unit>` - to add or subtract N time units.

Please note that the value of time shift can be greater or equal to 0, while the time period minimum value is 1.

| Parameter | Description |
|--------------------------|-------------|
| <code>1d:now/d</code> | Yesterday |
| <code>1d:now/d+1d</code> | Today |
| <code>2d:now/d+1d</code> | Last 2 days |
| <code>1w:now/w</code> | Last week |
| <code>1w:now/w+1w</code> | This week |

Other expressions

Function parameters may contain other expressions, as in the following syntax:

```
min(min(/host/key,1h),min(/host2/key2,1h)*10)
```

Note that other expressions may not be used, if the function references item history. For example, the following syntax is not allowed:

```
min(/host/key,#5*10)
```

Operators

The following operators are supported for triggers **(in descending priority of execution)**:

| Priority | Operator | Definition | Notes for unknown values | Force cast operand to float ¹ |
|----------|--------------|--|--|--|
| 1 | - | Unary minus | -Unknown → Unknown | Yes |
| 2 | not | Logical NOT | not Unknown → Unknown | Yes |
| 3 | * | Multiplication | 0 * Unknown → Unknown (yes, Unknown, not 0 - to not lose Unknown in arithmetic operations) 1.2 * Unknown → Unknown | Yes |
| | / | Division | Unknown / 0 → error Unknown / 1.2 → Unknown 0.0 / Unknown → Unknown | Yes |
| 4 | + | Arithmetical plus | 1.2 + Unknown → Unknown | Yes |
| | - | Arithmetical minus | 1.2 - Unknown → Unknown | Yes |
| 5 | < | Less than. The operator is defined as: $A < B \Leftrightarrow (A < B - 0.000001)$ | 1.2 < Unknown → Unknown | Yes |
| | <= | Less than or equal to. The operator is defined as: $A \leq B \Leftrightarrow (A \leq B + 0.000001)$ | Unknown <= Unknown → Unknown | Yes |
| | > | More than. The operator is defined as: $A > B \Leftrightarrow (A > B + 0.000001)$ | | Yes |

| Priority | Operator | Definition | Notes for unknown values | Force cast operand to float ¹ |
|----------|-----------------|---|--|--|
| | >= | More than or equal to. The operator is defined as: $A \geq B \Leftrightarrow (A \geq B - 0.000001)$ | | Yes |
| 6 | = | Is equal. The operator is defined as: $A = B \Leftrightarrow (A \geq B - 0.000001) \text{ and } (A \leq B + 0.000001)$ | | No ¹ |
| | <> | Not equal. The operator is defined as: $A <> B \Leftrightarrow (A < B - 0.000001) \text{ or } (A > B + 0.000001)$ | | No ¹ |
| 7 | and | Logical AND | 0 and Unknown → 0 1 and Unknown → Unknown Unknown and Unknown → Unknown | Yes |
| 8 | or | Logical OR | 1 or Unknown → 1 0 or Unknown → Unknown Unknown or Unknown → Unknown | Yes |

¹ String operand is still cast to numeric if:

- another operand is numeric
- operator other than = or <> is used on an operand

(If the cast fails - numeric operand is cast to a string operand and both operands get compared as strings.)

not, **and** and **or** operators are case-sensitive and must be in lowercase. They also must be surrounded by spaces or parentheses.

All operators, except unary - and **not**, have left-to-right associativity. Unary - and **not** are non-associative (meaning **-(-1)** and **not (not 1)** should be used instead of **--1** and **not not 1**).

Evaluation result:

- <, <=, >, >=, =, <> operators shall yield '1' in the trigger expression if the specified relation is true and '0' if it is false. If at least one operand is Unknown the result is Unknown;
- **and** for known operands shall yield '1' if both of its operands compare unequal to '0'; otherwise, it yields '0'; for unknown operands **and** yields '0' only if one operand compares equal to '0'; otherwise, it yields 'Unknown';
- **or** for known operands shall yield '1' if either of its operands compare unequal to '0'; otherwise, it yields '0'; for unknown operands **or** yields '1' only if one operand compares unequal to '0'; otherwise, it yields 'Unknown';
- The result of the logical negation operator **not** for a known operand is '0' if the value of its operand compares unequal to '0'; '1' if the value of its operand compares equal to '0'. For unknown operand **not** yields 'Unknown'.

Value caching

Values required for trigger evaluation are cached by Zabbix server. Because of this trigger evaluation causes a higher database load for some time after the server restarts. The value cache is not cleared when item history values are removed (either manually or by housekeeper), so the server will use the cached values until they are older than the time periods defined in trigger functions or server is restarted.

Note:

If there is no recent data in the cache and there is no defined querying period in the function, Zabbix will by default go as far back in the past as one week to query the database for historical values.

Examples of triggers

Example 1

The processor load is too high on Zabbix server.

```
last(/Zabbix server/system.cpu.load[all,avg1])>5
```

By using the function 'last()', we are referencing the most recent value. /Zabbix server/system.cpu.load[all,avg1] gives a short name of the monitored parameter. It specifies that the host is 'Zabbix server' and the key being monitored is 'system.cpu.load[all,avg1]'. Finally, >5 means that the trigger is in the PROBLEM state whenever the most recent processor load measurement from Zabbix server is greater than 5.

Example 2

www.example.com is overloaded.

```
last(/www.example.com/system.cpu.load[all,avg1])>5 or min(/www.example.com/system.cpu.load[all,avg1],10m)>2
```

The expression is true when either the current processor load is more than 5 or the processor load was more than 2 during last 10 minutes.

Example 3

/etc/passwd has been changed.

```
last(/www.example.com/vfs.file.cksum[/etc/passwd],#1)<>last(/www.example.com/vfs.file.cksum[/etc/passwd],#1)
```

The expression is true when the previous value of /etc/passwd checksum differs from the most recent one.

Similar expressions could be useful to monitor changes in important files, such as /etc/passwd, /etc/inetd.conf, /kernel, etc.

Example 4

Someone is downloading a large file from the Internet.

Use of function min:

```
min(/www.example.com/net.if.in[eth0,bytes],5m)>100K
```

The expression is true when number of received bytes on eth0 is more than 100 KB within last 5 minutes.

Example 5

Both nodes of clustered SMTP server are down.

Note use of two different hosts in one expression:

```
last(/smtp1.example.com/net.tcp.service[smtp])=0 and last(/smtp2.example.com/net.tcp.service[smtp])=0
```

The expression is true when both SMTP servers are down on both smtp1.example.com and smtp2.example.com.

Example 6

Zabbix agent needs to be upgraded.

Use of function find():

```
find(/example.example.com/agent.version,,"like","beta8")=1
```

The expression is true if Zabbix agent has version beta8.

Example 7

Server is unreachable.

```
count(/example.example.com/icmpping,30m,,"0")>5
```

The expression is true if host "example.example.com" is unreachable more than 5 times in the last 30 minutes.

Example 8

No heartbeats within last 3 minutes.

Use of function nodata():

```
nodata(/example.example.com/tick,3m)=1
```

To make use of this trigger, 'tick' must be defined as a Zabbix **trapper** item. The host should periodically send data for this item using `zabbix_sender`. If no data is received within 180 seconds, the trigger value becomes **PROBLEM**.

Note that 'nodata' can be used for any item type.

Example 9

CPU activity at night time.

Use of function `time()`:

```
min(/Zabbix_server/system.cpu.load[all,avg1],5m)>2 and time()<060000
```

The trigger may change its state to problem only at night time (00:00 - 06:00).

Example 10

CPU activity at any time with exception.

Use of function `time()` and **not** operator:

```
min(/zabbix/system.cpu.load[all,avg1],5m)>2
and not (dayofweek()=7 and time()>230000)
and not (dayofweek()=1 and time()<010000)
```

The trigger may change its state to problem at any time, except for 2 hours on a week change (Sunday, 23:00 - Monday, 01:00).

Example 11

Check if client local time is in sync with Zabbix server time.

Use of function `fuzzytime()`:

```
fuzzytime(/MySQL_DB/system.localtime,10s)=0
```

The trigger will change to the problem state in case when local time on server `MySQL_DB` and Zabbix server differs by more than 10 seconds. Note that 'system.localtime' must be configured as a **passive check**.

Example 12

Comparing average load today with average load of the same time yesterday (using time shift as `now-1d`).

```
avg(/server/system.cpu.load,1h)/avg(/server/system.cpu.load,1h:now-1d)>2
```

The trigger will fire if the average load of the last hour tops the average load of the same hour yesterday more than two times.

Example 13

Using the value of another item to get a trigger threshold:

```
last(/Template PfSense/hrStorageFree[{#SNMPVALUE}])<last(/Template PfSense/hrStorageSize[{#SNMPVALUE}])*0.1
```

The trigger will fire if the free storage drops below 10 percent.

Example 14

Using **evaluation result** to get the number of triggers over a threshold:

```
(last(/server1/system.cpu.load[all,avg1])>5) + (last(/server2/system.cpu.load[all,avg1])>5) + (last(/server3/system.cpu.load[all,avg1])>5)>2
```

The trigger will fire if at least two of the triggers in the expression are in a problem state.

Example 15

Comparing string values of two items - operands here are functions that return strings.

Problem: create an alert if Ubuntu version is different on different hosts

```
last(/NY_Zabbix_server/vfs.file.contents[/etc/os-release])<>last(/LA_Zabbix_server/vfs.file.contents[/etc/os-release])
```

Example 16

Comparing two string values - operands are:

- a function that returns a string
- a combination of macros and strings

Problem: detect changes in the DNS query

The item key is:

```
net.dns.record[192.0.2.0,{ $WEBSITE_NAME},{ $DNS_RESOURCE_RECORD_TYPE},2,1]
```

with macros defined as

```
{ $WEBSITE_NAME } = example.com  
{ $DNS_RESOURCE_RECORD_TYPE } = MX
```

and normally returns:

```
example.com          MX          0 mail.example.com
```

So our trigger expression to detect if the DNS query result deviated from the expected result is:

```
last(/Zabbix server/net.dns.record[192.0.2.0,{ $WEBSITE_NAME},{ $DNS_RESOURCE_RECORD_TYPE},2,1])<>"{ $WEBSITE
```

Notice the quotes around the second operand.

Example 17

Comparing two string values - operands are:

- a function that returns a string
- a string constant with special characters \ and "

Problem: detect if the /tmp/hello file content is equal to:

```
\ " //hello ? \"
```

Option 1) write the string directly

```
last(/Zabbix server/vfs.file.contents[/tmp/hello])="\\ \" //hello ?\\ \"
```

Notice how \ and " characters are escaped when the string gets compared directly.

Option 2) use a macro

```
{ $HELLO_MACRO } = \ " //hello ? \"
```

in the expression:

```
last(/Zabbix server/vfs.file.contents[/tmp/hello])={ $HELLO_MACRO }
```

Example 18

Comparing long-term periods.

Problem: Load of Exchange server increased by more than 10% last month

```
trendavg(/Exchange/system.cpu.load,1M:now/M)>1.1*trendavg(/Exchange/system.cpu.load,1M:now/M-1M)
```

You may also use the **Event name** field in trigger configuration to build a meaningful alert message, for example to receive something like

```
"Load of Exchange server increased by 24% in July (0.69) comparing to June (0.56)"
```

the event name must be defined as:

```
Load of {HOST.HOST} server increased by {{?100*trendavg(/system.cpu.load,1M:now/M)/trendavg(/system.cpu.
```

It is also useful to allow manual closing in trigger configuration for this kind of problem.

Hysteresis

Sometimes an interval is needed between problem and recovery states, rather than a simple threshold. For example, if we want to define a trigger that reports a problem when server room temperature goes above 20°C and we want it to stay in the problem state until the temperature drops below 15°C, a simple trigger threshold at 20°C will not be enough.

Instead, we need to define a trigger expression for the problem event first (temperature above 20°C). Then we need to define an additional recovery condition (temperature below 15°C). This is done by defining an additional *Recovery expression* parameter when **defining** a trigger.

In this case, problem recovery will take place in two steps:

- First, the problem expression (temperature above 20°C) will have to evaluate to FALSE
- Second, the recovery expression (temperature below 15°C) will have to evaluate to TRUE

The recovery expression will be evaluated only when the problem event is resolved first.

Warning:

The recovery expression being TRUE alone does not resolve a problem if the problem expression is still TRUE!

Example 1

Temperature in server room is too high.

Problem expression:

```
last(/server/temp)>20
```

Recovery expression:

```
last(/server/temp)<=15
```

Example 2

Free disk space is too low.

Problem expression: it is less than 10GB for last 5 minutes

```
max(/server/vfs.fs.size[/,free],5m)<10G
```

Recovery expression: it is more than 40GB for last 10 minutes

```
min(/server/vfs.fs.size[/,free],10m)>40G
```

Expressions with unknown operands

Generally an unknown operand (such as an unsupported item) in the expression will immediately render the trigger value to `Unknown`.

However, in some cases unknown operands (unsupported items, function errors) are admitted into expression evaluation:

- The `nodata()` function is evaluated regardless of whether the referenced item is supported or not.
- Logical expressions with OR and AND can be evaluated to known values in two cases regardless of unknown operands:
 - **Case 1:** "1 or some_function(unsupported_item1) or some_function(unsupported_item2) or ..." can be evaluated to known result ('1' or "Problem"),
 - **Case 2:** "0 and some_function(unsupported_item1) and some_function(unsupported_item2) and ..." can be evaluated to known result ('0' or "OK").Zabbix tries to evaluate such logical expressions by taking unsupported items as unknown operands. In the two cases above a known value will be produced ("Problem" or "OK", respectively); in **all other** cases the trigger will evaluate to `Unknown`.
- If the function evaluation for a supported item results in error, the function value becomes `Unknown` and it takes part as unknown operand in further expression evaluation.

Note that unknown operands may "disappear" only in logical expressions as described above. In arithmetic expressions unknown operands always lead to the result `Unknown` (except division by 0).

Attention:

An expression that results in `Unknown` does not change the trigger state ("Problem/OK"). So, if it was "Problem" (see Case 1), it stays in the same problem state even if the known part is resolved ('1' becomes '0'), because the expression is now evaluated to `Unknown` and that does not change the trigger state.

If a trigger expression with several unsupported items evaluates to `Unknown` the error message in the frontend refers to the last unsupported item evaluated.

3 Trigger dependencies

Overview

Sometimes the availability of one host depends on another. A server that is behind a router will become unreachable if the router goes down. With triggers configured for both, you might get notifications about two hosts down - while only the router was the guilty party.

This is where some dependency between hosts might be useful. With dependency set, notifications of the dependents could be withheld and only the notification on the root problem sent.

While Zabbix does not support dependencies between hosts directly, they may be defined with another, more flexible method - trigger dependencies. A trigger may have one or more triggers it depends on.

So in our simple example we open the server trigger configuration form and set that it depends on the respective trigger of the router. With such dependency, the server trigger will not change its state as long as the trigger it depends on is in the 'PROBLEM' state - and thus no dependent actions will be taken and no notifications sent.

If both the server and the router are down and dependency is there, Zabbix will not execute actions for the dependent trigger.

While the parent trigger is in the PROBLEM state, its dependents may report values that cannot be trusted. Therefore dependent triggers will not be re-evaluated until the parent trigger (the router in the example above):

- goes back from 'PROBLEM' to 'OK' state;
- changes its state from 'PROBLEM' to 'UNKNOWN';
- is closed manually, by correlation or with the help of **date and time** and/or **nodata()** functions;
- is resolved by a value of an item not involved in the dependent trigger;
- is disabled, has a disabled item or a disabled item host

In all of the cases mentioned above, the dependent trigger (server) will be re-evaluated only when a new metric for it is received. This means that the dependent trigger may not be updated immediately.

Also:

- Trigger dependency may be added from any host trigger to any other host trigger, as long as it doesn't result in a circular dependency.
- Trigger dependency may be added from one template to another. If some trigger from template A depends on some trigger from template B, template A may only be linked to a host (or another template) together with template B, but template B may be linked to a host (or another template) alone.
- Trigger dependency may be added from a template trigger to a host trigger. In this case, linking such a template to a host will create a host trigger that depends on the same trigger template that the trigger was depending on. This allows to, for example, have a template where some triggers depend on the router (host) triggers. All hosts linked to this template will depend on that specific router.
- Trigger dependency may not be added from a host trigger to a template trigger.
- Trigger dependency may be added from a trigger prototype to another trigger prototype (within the same low-level discovery rule) or a real trigger. A trigger prototype may not depend on a trigger prototype from a different LLD rule or on a trigger created from trigger prototype. A host trigger prototype cannot depend on a trigger from a template.

Configuration

To define a dependency, open the Dependencies tab in the trigger **configuration form**. Click on *Add* in the 'Dependencies' block and select one or more triggers that the trigger will depend on.

| Name | Action |
|--|------------------------|
| My host: Load average is too high (per CPU load over {\$LOAD_AVG_PER_CPU.MAX.WARN} for 5m) | Remove |

[Add](#)

[Update](#) [Clone](#) [Delete](#) [Cancel](#)

Click *Update*. Now the trigger has the indication of its dependency in the list.

Template Module Linux CPU by Zabbix agent: High CPU utilization
(over {\$CPU.UTIL.CRIT}% for 5m)
Depends on:
My host: Load average is too high (per CPU load over
{\$LOAD_AVG_PER_CPU.MAX.WARN} for 5m)

Example of several dependencies

For example, the Host is behind the Router2 and the Router2 is behind the Router1.

Zabbix - Router1 - Router2 - Host

If the Router1 is down, then obviously the Host and the Router2 are also unreachable, yet receiving three notifications about the Host, the Router1 and the Router2 all being down is excessive.

So in this case we define two dependencies:

```
the 'Host is down' trigger depends on the 'Router2 is down' trigger
the 'Router2 is down' trigger depends on the 'Router1 is down' trigger
```

Before changing the status of the 'Host is down' trigger, Zabbix will check for the corresponding trigger dependencies. If such are found and one of those triggers is in the 'Problem' state, then the trigger status will not be changed, the actions will not be executed and no notifications will be sent.

Zabbix performs this check recursively. If the Router1 or the Router2 is unreachable, the Host trigger won't be updated.

4 Trigger severity

Trigger severity represents the level of importance of a trigger.

Severity Not classified Information Warning Average High Disaster

Zabbix supports the following default trigger severities.

| Severity | Color | Description |
|----------------|------------|---|
| Not classified | Gray | Can be used where the severity level of an event is unknown, has not been determined, is not part of the regular monitoring scope, etc., for example, during initial configuration, as a placeholder for future assessment, or as part of an integration process. |
| Information | Light blue | Can be used for informational events that do not require immediate attention, but can still provide valuable insights. |
| Warning | Yellow | Can be used to indicate a potential issue that might require investigation or action, but that is not critical. |
| Average | Orange | Can be used to indicate a significant issue that should be addressed relatively soon to prevent further problems. |
| High | Light red | Can be used to indicate critical issues that need immediate attention to avoid significant disruptions. |
| Disaster | Red | Can be used to indicate a severe incident that requires immediate action to prevent, for example, system outages or data loss. |

Note:

Trigger severity names and colors can be **customized**.

Trigger severities are used for:

- visual representation of triggers - different colors for different severities;
- audio in global alarms - different audio for different severities;
- user media - different media (notification channel) for different severities (for example, SMS for triggers of *High* and *Disaster* severity, and Email for triggers of other severities);
- limiting actions by conditions against trigger severities.

5 Customizing trigger severities

Trigger severity names and colors for severity related GUI elements can be configured in *Administration* → *General* → *Trigger displaying options*. Colors are shared among all GUI themes.

Translating customized severity names

Attention:

If Zabbix frontend translations are used, custom severity names will override translated names by default.

Default trigger severity names are available for translation in all locales. If a severity name is changed, a custom name is used in all locales and additional manual translation is needed.

Custom severity name translation procedure:

- set required custom severity name, for example, 'Important'
- edit `<frontend_dir>/locale/<required_locale>/LC_MESSAGES/frontend.po`
- add 2 lines:

```
msgid "Important"
msgstr "<translation string>"
```

and save file.

- create .mo files as described in <frontend_dir>/locale/README

Here **msgid** should match the new custom severity name and **msgstr** should be the translation for it in the specific language.

This procedure should be performed after each severity name change.

6 Mass update

Overview

With mass update you may change some attribute for a number of triggers at once, saving you the need to open each individual trigger for editing.

Using mass update

To mass-update some triggers, do the following:

- Mark the checkboxes of the triggers you want to update in the list
- Click on *Mass update* below the list
- Navigate to the tab with required attributes (*Trigger*, *Tags* or *Dependencies*)
- Mark the checkboxes of any attribute to update

Mass update

Trigger Tags Dependencies

Severity ☒ Not classified Information Warning Average High Disaster

Allow manual close ☐ Original

Mass update

Trigger Tags Dependencies

Tags ☒ Add Replace Remove

Name Value

tag value

Add

The following options are available when selecting the respective button for tag update:

- *Add* - allows to add new tags for the triggers;
- *Replace* - will remove any existing tags from the trigger and replace them with the one(s) specified below;
- *Remove* - will remove specified tags from triggers.

Note that tags with the same name but different values are not considered 'duplicates' and can be added to the same trigger.

Mass update

Trigger Tags Dependencies

Replace dependencies ☒

Name

Zabbix server: Lack of available memory (< 20M of 7.72 GB)

Add

Replace dependencies - will remove any existing dependencies from the trigger and replace them with the one(s) specified.

Click on *Update* to apply the changes.

7 Predictive trigger functions

Overview

Sometimes there are signs of the upcoming problem. These signs can be spotted so that actions may be taken in advance to prevent or at least minimize the impact of the problem.

Zabbix has tools to predict the future behavior of the monitored system based on historic data. These tools are realized through predictive trigger functions.

Functions

Before setting a trigger, it is necessary to define what a problem state is and how much time is needed to take action. Then there are two ways to set up a trigger signaling about a potential unwanted situation. First: the trigger must fire when the system is expected to be in a problem state after "time to act". Second: the trigger must fire when the system is going to reach the problem state in less than "time to act". Corresponding trigger functions to use are **forecast** and **timeleft**. Note that underlying statistical analysis is basically identical for both functions. You may set up a trigger whichever way you prefer with similar results.

Parameters

Both functions use almost the same set of parameters. Use the list of **supported functions** for reference.

Time interval

First of all, you should specify the historic period Zabbix should analyze to come up with the prediction. You do it in a familiar way by means of the `time` `period` parameter and optional time shift like you do it with **avg**, **count**, **delta**, **max**, **min** and **sum** functions.

Forecasting horizon

(**forecast** only)

Parameter `time` specifies how far in the future Zabbix should extrapolate dependencies it finds in historic data. No matter if you use `time_shift` or not, `time` is always counted starting from the current moment.

Threshold to reach

(**timeleft** only)

Parameter `threshold` specifies a value the analyzed item has to reach, no difference if from above or from below. Once we have determined $f(t)$ (see below), we should solve equation $f(t) = \text{threshold}$ and return the root which is closer to now and to the right from now or $1.7976931348623158E+308$ if there is no such root.

Note:

When item values approach the threshold and then cross it, **timeleft** assumes that intersection is already in the past and therefore switches to the next intersection with `threshold` level, if any. Best practice should be to use predictions as a complement to ordinary problem diagnostics, not as a substitution.¹

Fit functions

Default `fit` is the *linear* function. But if your monitored system is more complicated you have more options to choose from.

| fit | $x = f(t)$ |
|--------|-----------------|
| linear | $x = a + b * t$ |

| fit | $x = f(t)$ |
|--------------------------------|---|
| <i>polynomial</i> ² | $x = a_0 + a_1*t + a_2*t^2 + \dots + a_n*t^n$ |
| <i>exponential</i> | $x = a*\exp(b*t)$ |
| <i>logarithmic</i> | $x = a + b*\log(t)$ |
| <i>power</i> | $x = a*t^b$ |

Modes

(forecast only)

Every time a trigger function is evaluated, it gets data from the specified history period and fits a specified function to the data. So, if the data is slightly different, the fitted function will be slightly different. If we simply calculate the value of the fitted function at a specified time in the future, you will know nothing about how the analyzed item is expected to behave between now and that moment in the future. For some *fit* options (like *polynomial*) a simple value from the future may be misleading.

| mode | forecast result |
|--------------|---|
| <i>value</i> | $f(\text{now} + \text{time})$ |
| <i>max</i> | $\max_{\text{now} \leq t \leq \text{now} + \text{time}} f(t)$ |
| <i>min</i> | $\min_{\text{now} \leq t \leq \text{now} + \text{time}} f(t)$ |
| <i>delta</i> | $\text{max} - \text{min}$ |
| <i>avg</i> | average of $f(t)$ ($\text{now} \leq t \leq \text{now} + \text{time}$) according to definition |

Details

To avoid calculations with huge numbers, we consider the timestamp of the first value in specified period plus 1 ns as a new zero-time (current epoch time is of order 10^9 , epoch squared is 10^{18} , double precision is about 10^{-16}). 1 ns is added to provide all positive time values for *logarithmic* and *power* fits which involve calculating $\log(t)$. Time shift does not affect *linear*, *polynomial*, *exponential* (apart from easier and more precise calculations) but changes the shape of *logarithmic* and *power* functions.

Potential errors

Functions return -1 in such situations:

- specified evaluation period contains no data;
- result of mathematical operation is not defined³;
- numerical complications (unfortunately, for some sets of input data range and precision of double-precision floating-point format become insufficient)⁴.

Note:

No warnings or errors are flagged if chosen fit poorly describes provided data or there is just too few data for accurate prediction.

Examples and dealing with errors

To get a warning when you are about to run out of free disk space on your host, you may use a trigger expression like this:

```
timeleft(/host/vfs.fs.size[/,free],1h,0)<1h
```

However, error code -1 may come into play and put your trigger in a problem state. Generally it's good because you get a warning that your predictions don't work correctly and you should look at them more thoroughly to find out why. But sometimes it's bad because -1 can simply mean that there was no data about the host free disk space obtained in the last hour. If you are getting too many false positive alerts, consider using more complicated trigger expression⁵:

```
timeleft(/host/vfs.fs.size[/,free],1h,0)<1h and timeleft(/host/vfs.fs.size[/,free],1h,0)<>-1
```

The situation is a bit more difficult with **forecast**. First of all, -1 may or may not put the trigger in a problem state depending on whether you have expression like `forecast(/host/item,...)<...` or like `forecast(/host/item,...)>...`

Furthermore, -1 may be a valid forecast if it's normal for the item value to be negative. But probability of this situation in the real world situation is negligible (see [how the operator = works](#)). So add `... or forecast(/host/item,...)=-1` or `... and forecast(/host/item,...)<>-1` if you want or don't want to treat -1 as a problem respectively.

Footnotes

¹ For example, a simple trigger like `timeleft(/host/item,1h,X) < 1h` may go into problem state when the item value approaches X and then suddenly recover once value X is reached. If the problem is item value being below X, use: `last(/host/item) < X` or `timeleft(/host/item,1h,X) < 1h` If the problem is item value being above X use: `last(/host/item) > X` or `timeleft(/host/item,1h,X) < 1h`

² Polynomial degree can be from 1 to 6, *polynomial1* is equivalent to *linear*. However, use higher degree polynomials [with caution](#). If the evaluation period contains less points than needed to determine polynomial coefficients, polynomial degree will be lowered (e.g., *polynomial5* is requested, but there are only 4 points, therefore *polynomial3* will be fitted).

³ For example, fitting *exponential* or *power* functions involves calculating $\log()$ of item values. If data contains zeros or negative numbers, you will get an error since $\log()$ is defined for positive values only.

⁴ For *linear*, *exponential*, *logarithmic* and *power* fits all necessary calculations can be written explicitly. For *polynomial* only *value* can be calculated without any additional steps. Calculating *avg* involves computing polynomial antiderivative (analytically). Computing *max*, *min* and *delta* involves computing polynomial derivative (analytically) and finding its roots (numerically). Solving $f(t) = 0$ involves finding polynomial roots (numerically).

⁵ But in this case -1 can cause your trigger to recover from the problem state. To be fully protected use: `timeleft(/host/vfs.fs.size[/,free],1h,0)<>-1` or `{TRIGGER.VALUE}=1`

4 Events

Overview

There are several types of events generated in Zabbix:

- trigger events - whenever a trigger changes its status (*OK*→*PROBLEM*→*OK*)
- service events - whenever a service changes its status (*OK*→*PROBLEM*→*OK*)
- discovery events - when hosts or services are detected
- autoregistration events - when active agents are auto-registered by server
- internal events - when an item/low-level discovery rule becomes unsupported or a trigger goes into an unknown state

Events are time-stamped and can be the basis of actions such as sending notification email etc.

To view details of events in the frontend, go to *Monitoring* → *Problems*. There you can click on the event date and time to view details of an event.

More information is available on:

- [trigger events](#)
- [other event sources](#)

1 Trigger event generation

Overview

Change of trigger status is the most frequent and most important source of events. Each time the trigger changes its state, an event is generated. The event contains details of the trigger state's change - when it happened and what the new state is.

Two types of events are created by triggers - Problem and OK.

Problem events

A problem event is created:

- when a trigger expression evaluates to TRUE if the trigger is in OK state;
- each time a trigger expression evaluates to TRUE if multiple problem event generation is enabled for the trigger.

OK events

An OK event closes the related problem event(s) and may be created by 3 components:

- triggers - based on 'OK event generation' and 'OK event closes' settings;
- event correlation
- task manager - when an event is [manually closed](#)

Triggers

Triggers have an 'OK event generation' setting that controls how OK events are generated:

- *Expression* - an OK event is generated for a trigger in problem state when its expression evaluates to FALSE. This is the simplest setting, enabled by default.
- *Recovery expression* - an OK event is generated for a trigger in problem state when its expression evaluates to FALSE and the recovery expression evaluates to TRUE. This can be used if trigger recovery criteria is different from problem criteria.

- *None* - an OK event is never generated. This can be used in conjunction with multiple problem event generation to simply send a notification when something happens.

Additionally triggers have an 'OK event closes' setting that controls which problem events are closed:

- *All problems* - an OK event will close all open problems created by the trigger
- *All problems if tag values match* - an OK event will close open problems created by the trigger and having at least one matching tag value. The tag is defined by 'Tag for matching' trigger setting. If there are no problem events to close then OK event is not generated. This is often called trigger level event correlation.

Event correlation

Event correlation (also called global event correlation) is a way to set up custom event closing (resulting in OK event generation) rules.

The rules define how the new problem events are paired with existing problem events and allow to close the new event or the matched events by generating corresponding OK events.

However, event correlation must be configured very carefully, as it can negatively affect event processing performance or, if misconfigured, close more events than intended (in the worst case even all problem events could be closed). A few configuration tips:

1. always reduce the correlation scope by setting a unique tag for the control event (the event that is paired with old events) and use the 'new event tag' correlation condition
2. don't forget to add a condition based on the old event when using 'close old event' operation, or all existing problems could be closed
3. avoid using common tag names used by different correlation configurations

Task manager

If the 'Allow manual close' setting is enabled for trigger, then it's possible to manually close problem events generated by the trigger. This is done in the frontend when **updating a problem**. The event is not closed directly – instead a 'close event' task is created, which is handled by the task manager shortly. The task manager will generate a corresponding OK event and the problem event will be closed.

2 Other event sources

Service events

Service events are generated only if service actions for these events are enabled. In this case, each service status change creates a new event:

- Problem event - when service status is changed from OK to PROBLEM
- OK event - when service status is changed from PROBLEM to OK

The event contains details of the service state change - when it happened and what the new state is.

Discovery events

Zabbix periodically scans the IP ranges defined in network discovery rules. Frequency of the check is configurable for each rule individually. Once a host or a service is discovered, a discovery event (or several events) are generated.

Zabbix generates the following events:

| Event | When generated |
|--------------------|---|
| Service Up | Every time Zabbix detects active service. |
| Service Down | Every time Zabbix cannot detect service. |
| Host Up | If at least one of the services is UP for the IP. |
| Host Down | If all services are not responding. |
| Service Discovered | If the service is back after downtime or discovered for the first time. |
| Service Lost | If the service is lost after being up. |
| Host Discovered | If host is back after downtime or discovered for the first time. |
| Host Lost | If host is lost after being up. |

Active agent autoregistration events

Active agent autoregistration creates events in Zabbix.

If configured, active agent autoregistration event is created when a previously unknown active agent asks for checks or if the host metadata has changed. The server adds a new auto-registered host, using the received IP address and port of the agent.

For more information, see the [active agent autoregistration](#) page.

Internal events

Internal events happen when:

- an item changes state from 'normal' to 'unsupported'
- an item changes state from 'unsupported' to 'normal'
- a low-level discovery rule changes state from 'normal' to 'unsupported'
- a low-level discovery rule changes state from 'unsupported' to 'normal'
- a trigger changes state from 'normal' to 'unknown'
- a trigger changes state from 'unknown' to 'normal'

The aim of introducing internal events is to allow users to be notified when any internal event takes place, for example, an item becomes unsupported and stops gathering data.

Internal events are only created when internal actions for these events are enabled. To stop generation of internal events (for example, for items becoming unsupported), disable all actions for internal events in Alerts → Actions → Internal actions.

Note:

If internal actions are disabled, while an object is in the 'unsupported' state, recovery event for this object will still be created.

If internal actions are enabled, while an object is in the 'unsupported' state, recovery event for this object will be created, even though 'problem event' has not been created for the object.

See also: [Receiving notification on unsupported items](#)

3 Manual closing of problems

Overview

While generally problem events are resolved automatically when trigger status goes from 'Problem' to 'OK', there may be cases when it is difficult to determine if a problem has been resolved by means of a trigger expression. In such cases, the problem needs to be resolved manually.

For example, *syslog* may report that some kernel parameters need to be tuned for optimal performance. In this case the issue is reported to Linux administrators, they fix it and then close the problem manually.

Problems can be closed manually only for triggers with the *Allow manual close* option enabled.

When a problem is "manually closed", Zabbix generates a new internal task for Zabbix server. Then the *task manager* process executes this task and generates an OK event, therefore closing problem event.

A manually closed problem does not mean that the underlying trigger will never go into a 'Problem' state again. The trigger expression is re-evaluated and may result in a problem:

- When new data arrive for any item included in the trigger expression (note that the values discarded by a throttling preprocessing step are not considered as received and will not cause trigger expression to be re-evaluated);
- When **date and time** and/or **nodata()** functions are used in the expression.

Configuration

Two steps are required to close a problem manually.

Trigger configuration

In trigger configuration, enable the *Allow manual close* option.

Allow manual close ☒

Problem update window

If a problem arises for a trigger with the *Manual close* flag, you can open the **problem update** popup window of that problem and close the problem manually.

To close the problem, check the *Close problem* option in the form and click on *Update*.

Update problem

Message

Fixed, closing.

Update

Cancel

All mandatory input fields are marked with a red asterisk.

The request is processed by Zabbix server. Normally it will take a few seconds to close the problem. During that process *CLOSING* is displayed in *Monitoring* → *Problems* as the status of the problem.

Verification

It can be verified that a problem has been closed manually:

- in event details, available through *Monitoring* → *Problems*;
- by using the {EVENT.UPDATE.HISTORY} macro in notification messages that will provide this information.

5 Event correlation

Overview

Event correlation allows to correlate problem events to their resolution in a manner that is very precise and flexible.

Event correlation can be defined:

- **on trigger level** - one trigger may be used to relate separate problems to their solution
- **globally** - problems can be correlated to their solution from a different trigger/polling method using global correlation rules

1 Trigger-based event correlation

Overview

Trigger-based event correlation allows to correlate separate problems reported by one trigger.

While generally an OK event can close all problem events created by one trigger, there are cases when a more detailed approach is needed. For example, when monitoring log files you may want to discover certain problems in a log file and close them individually rather than all together.

This is the case with triggers that have *PROBLEM event generation mode* parameter set to *Multiple*. Such triggers are normally used for log monitoring, trap processing, etc.

It is possible in Zabbix to relate problem events based on **tagging**. Tags are used to extract values and create identification for problem events. Taking advantage of that, problems can also be closed individually based on matching tag.

In other words, the same trigger can create separate events identified by the event tag. Therefore problem events can be identified one-by-one and closed separately based on the identification by the event tag.

How it works

In log monitoring you may encounter lines similar to these:

```
Line1: Service 1 stopped
Line2: Service 2 stopped
Line3: Service 1 was restarted
Line4: Service 2 was restarted
```

The idea of event correlation is to be able to match the problem event from Line1 to the resolution from Line3 and the problem event from Line2 to the resolution from Line4, and close these problems one by one:

```
Line1: Service 1 stopped
Line3: Service 1 was restarted #problem from Line 1 closed
```

```
Line2: Service 2 stopped
Line4: Service 2 was restarted #problem from Line 2 closed
```

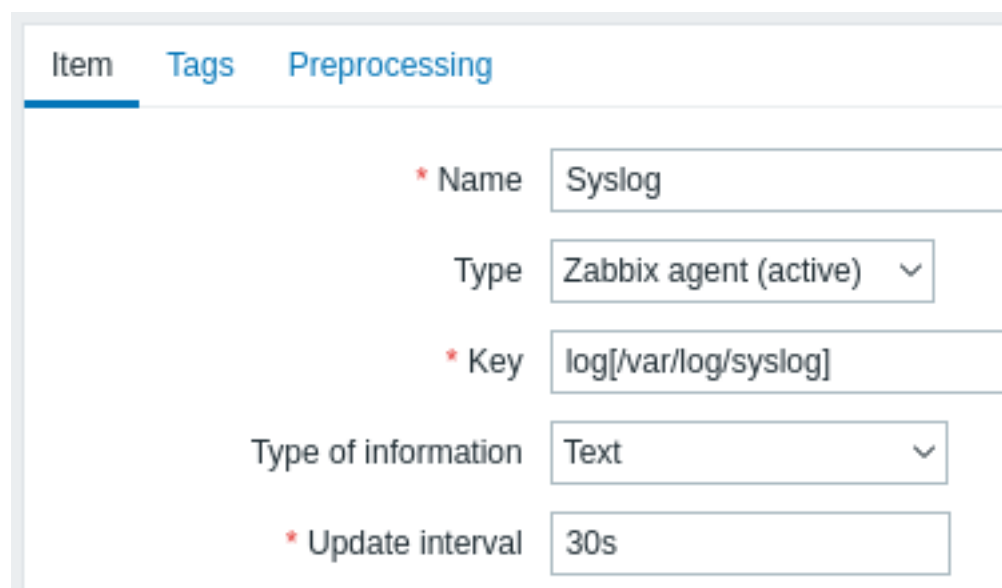

To do this you need to tag these related events as, for example, "Service 1" and "Service 2". That can be done by applying a regular expression to the log line to extract the tag value. Then, when events are created, they are tagged "Service 1" and "Service 2" respectively and problem can be matched to the resolution.

Configuration

Item

To begin with, you may want to set up an item that monitors a log file, for example:

```
log[/var/log/syslog]
```

| Item | Tags | Preprocessing |
|--|------|---------------|
| <div>* Name <input type="text" value="Syslog"/></div> <div>Type <input type="text" value="Zabbix agent (active)"/></div> <div>* Key <input type="text" value="log[/var/log/syslog]"/></div> <div>Type of information <input type="text" value="Text"/></div> <div>* Update interval <input type="text" value="30s"/></div> | | |

With the item set up, wait a minute for the configuration changes to be picked up and then go to **Latest data** to make sure that the item has started collecting data.

Trigger

With the item working you need to configure the **trigger**. It's important to decide what entries in the log file are worth paying attention to. For example, the following trigger expression will search for a string like 'Stopping' to signal potential problems:

```
find(/My host/log[/var/log/syslog],,"regex","Stopping")=1
```

Attention:

To make sure that each line containing the string "Stopping" is considered a problem also set the *Problem event generation mode* in trigger configuration to 'Multiple'.

Then define a recovery expression. The following recovery expression will resolve all problems if a log line is found containing the string "Starting":

```
find(/My host/log[/var/log/syslog],,"regexp","Starting")=1
```

Since we do not want that it's important to make sure somehow that the corresponding root problems are closed, not just all problems. That's where tagging can help.

Problems and resolutions can be matched by specifying a tag in the trigger configuration. The following settings have to be made:

- *Problem event generation mode*: Multiple
- *OK event closes*: All problems if tag values match
- Enter the name of the tag for event matching

Warning:

Because misconfiguration is possible, when similar event tags may be created for **unrelated** problems, please review the cases outlined below!

- Indexed macros always refer to the *Expression* field of the trigger configuration, not the *Recovery expression*. For example, in a recovery event, **{ITEM.VALUE1}** will resolve to the latest value of the first item **in the problem expression** at the time of recovery. If the recovery expression is based on a different item and the value of the problem expression item changes by the time of recovery, the events will get different tags and will not be correlated.
- With two applications writing error and recovery messages to the same log file a user may decide to use two *service* tags in the same trigger with different tag values by using separate regular expressions in the tag values to extract the names of, say, service A and service B from the {ITEM.VALUE} macro (e.g. when the message formats differ). However, this may not work as planned if there is no match to the regular expressions. Non-matching regexps will yield empty tag values and a single empty tag value in both problem and OK events is enough to correlate them. So a recovery message from service A may accidentally close an error message from service B.
- Actual tags and tag values only become visible when a trigger fires. If the regular expression used is invalid, it is silently replaced with an *UNKNOWN* string. If the initial problem event with an *UNKNOWN* tag value is missed, there may appear subsequent OK events with the same *UNKNOWN* tag value that may close problem events which they shouldn't have closed.
- If a user uses the {ITEM.VALUE} macro without macro functions as the tag value, the 255-character limitation applies. When log messages are long and the first 255 characters are non-specific, this may also result in similar event tags for unrelated problems.

2 Global event correlation

Overview

Global event correlation allows to reach out over all metrics monitored by Zabbix and create correlations.

It is possible to correlate events created by completely different triggers and apply the same operations to them all. By creating intelligent correlation rules it is actually possible to save yourself from thousands of repetitive notifications and focus on root causes of a problem!

Global event correlation is a powerful mechanism, which allows you to untie yourself from one-trigger based problem and resolution logic. So far, a single problem event was created by one trigger and we were dependent on that same trigger for the problem resolution. We could not resolve a problem created by one trigger with another trigger. But with event correlation based on event tagging, we can.

For example, a log trigger may report application problems, while a polling trigger may report the application to be up and running. Taking advantage of event tags you can tag the log trigger as *status:down* while tag the polling trigger as *status:up*. Then, in a global correlation rule you can relate these triggers and assign an appropriate operation to this correlation such as closing the old events.

In another use, global correlation can identify similar triggers and apply the same operation to them. What if we could get only one problem report per network port problem? No need to report them all. That is also possible with global event correlation.

Global event correlation is configured in **correlation rules**. A correlation rule defines how the new problem events are paired with existing problem events and what to do in case of a match (close the new event, close matched old events by generating corresponding OK events). If a problem is closed by global correlation, it is reported in the *Info* column of *Monitoring > Problems*.

Configuring global correlation rules is available to Super Admin level users only.

Attention:

Event correlation must be configured very carefully, as it can negatively affect event processing performance or, if mis-configured, close more events than was intended (in the worst case even all problem events could be closed).

To configure global correlation **safely**, observe the following important tips:

- Reduce the correlation scope. Always set a unique tag for the new event that is paired with old events and use the *New event tag name* correlation condition;
- Add a condition based on the old event when using the *Close old event* operation (or else all existing problems could be closed);
- Avoid using common tag names that may end up being used by different correlation configurations;
- Keep the number of correlation rules limited to the ones you really need.

See also: [known issues](#).

Configuration

To configure event correlation rules globally:

- Go to *Data collection > Event correlation*
- Click on *Create event correlation* to the right (or on the correlation name to edit an existing rule)
- Enter parameters of the correlation rule in the form

New event correlation

This global correlation rule will correlate problems if *host* and *port* tag values exist on the trigger and they are the same in the original event and the new one.

The operation will close new problem events on the same network port, keeping only the original problem open.

6 Tagging

Overview

Tags consist of a tag name and a tag value. When tagging entities, you can use just the name or pair it with a value (for example, `mysql`, `jira`, `target:mysql`, `service:jira`, etc.).

Tags can be defined for various entities:

- Templates
- Hosts
- Items
- Web scenarios
- Triggers
- Services
- Template items and triggers
- Host, item, and trigger prototypes

Note:

Refer to the official Zabbix guidelines for [general recommendations](#) on defining tags, along with specific guidance for [templates](#), [items](#), [triggers](#), and [low-level discovery rules](#).

Tags have multiple purposes, most notably, to mark **events**. When entities are tagged, any new event related to a tagged entity will inherit its tags. For example:

- with tagged templates - any host problem (created by triggers from the template) will inherit the template tags;
- with tagged hosts - any host problem will inherit the host tags;
- with tagged items/web scenarios - any item/web scenario problem will inherit the item/web scenario tags;
- with tagged triggers - any problem created by the trigger will inherit the trigger tags.

A problem event inherits all tags from the whole chain of entities - templates, hosts, items/web scenarios, triggers. Identical tag:value combinations (after resolved macros) are merged into one, thus avoiding duplication.

Custom event tags offer more flexibility. For example:

- **event correlation** can be configured based on event tags;
- **action conditions** can be configured based on event tags;

- item problems can be grouped based on event tags;
- problem tags can be used to map problems to **services**.

Entities may be tagged with the same tag name but different tag values (for example, `component:memory` and `component:storage`). Similarly, an entity can have a tag without a value and the same tag with a value (for example, `database` and `database:postgresql`). Such tags are not considered duplicates.

Use cases

Some common use cases for tagging are as follows:

1. Mark trigger events:
 - Define a trigger tag (for example, `scope:performance`).
 - Problems created by this trigger will have the trigger tag.
2. Mark template-inherited problems:
 - Define a template tag (for example, `target:mysql`).
 - Problems created by triggers from this template will have the template tag.
3. Mark host problems:
 - Define a host tag (for example, `service:jira`).
 - Problems created by triggers from this host will have the host tag.
4. Filter related items:
 - Define an item tag (for example, `component:cpu`).
 - In *Monitoring* → **Latest data**, items can be filtered by the `component:cpu` tag.
5. Use information extracted from the item value as the tag value:
 - Define a tag with a macro as the tag value (for example, `tag-name:{{ITEM.VALUE<N>}.regsub()}}`).
 - In *Monitoring* → **Problems**, problems will have the tag value resolved to the data extracted from the item value.
6. Identify problems in a log file and close them separately:
 - Define a trigger tag for the **log monitoring item** trigger that will extract values from the item value using a macro (for example, `service:{{ITEM.VALUE<N>}.regsub()}}`).
 - In the **trigger configuration**, set up **event correlation**:
 - set *PROBLEM event generation mode* to "Multiple";
 - set *OK event closes* to "All problems if tag values match";
 - set the tag for matching.
 - Problems created by the log item trigger will have the trigger tag and will be closed individually.
7. Filter notifications:
 - Define trigger tags (for example, `scope:security` for trigger1 and `scope:availability` for trigger2).
 - Use tag filtering in **action conditions** to receive notifications only on the events that match tag data.
8. Identify problems in notifications:
 - Define trigger tags.
 - Use the **{EVENT.TAGS}** macro in the problem notification.
 - The problem notification will contain the trigger tags, making it easier to identify which application/service the notification belongs to.
9. Simplify configuration tasks by using template tags:
 - Define a template trigger tag.
 - Triggers created from this template trigger will have its tag.
10. Create triggers with tags from low-level discovery (LLD):
 - Define a trigger prototype tag with an LLD macro in the tag name or value (for example, `scope:{{#FSNAME}}`).
 - Triggers created from the trigger prototype will have its tag.
11. Match services using service tags:
 - Define **service tags**.
 - Configure **service actions** for services with matching tags.
 - Additionally, use service tags to link a service to an **SLA** for SLA calculations.
12. Link services to problems using service problem tags:
 - Define a **problem tag** in **service configuration** (for example, `target:mysql`).
 - Problems with a matching tag will be automatically correlated to the service, and service status will change based on the configured service status calculation rules.
13. Suppress problems when a host is in maintenance mode:
 - Define tags in **maintenance period configuration**.
 - Problems with the defined tags will be suppressed.
14. Grant access to user groups:
 - Define tags in **user group configuration**.
 - Users in the user group will be able to view only problems with the defined tags.

Configuration

Tags can be defined in a dedicated tab, for example, in **trigger configuration**:

New trigger

Trigger
Tags 4
Dependencies

Trigger tags
Inherited and trigger tags

Tags

| Name | Value |
|----------|--|
| scope | capacity |
| scope | performance |
| customer | value |
| host | {{ITEM.VALUE2}.iregsub(pattern, output)} |

Macro support

Built-in and **user macros** in tags are resolved at the time of the event. Until the event has occurred, these macros will be shown in Zabbix frontend unresolved.

Low-level discovery macros are resolved during discovery process.

The following macros may be used in trigger tag names and values:

- {ITEM.VALUE}, {ITEM.LASTVALUE}, {HOST.HOST}, {HOST.NAME}, {HOST.CONN}, {HOST.DNS}, {HOST.IP}, {HOST.PORT}, and {HOST.ID} built-in macros
- {INVENTORY.*} built-in macros (for referencing host inventory values from one or several hosts in a trigger expression)
- User macros and user macros with context (the context may include low-level discovery macros)
- Low-level discovery macros (only in trigger prototype tags)

The following macros may be used in template, host, and item/web scenario tag names and values:

- {HOST.HOST}, {HOST.NAME}, {HOST.CONN}, {HOST.DNS}, {HOST.IP}, {HOST.PORT} and {HOST.ID} built-in macros
- {INVENTORY.*} built-in macros
- User macros
- Low-level discovery macros (only in host and item prototype tags)

The following macros may be used in trigger-based notifications:

- {EVENT.TAGS} and {EVENT.RECOVERY.TAGS} built-in macros (these macros will resolve to a comma-separated list of event tags or recovery event tags)
- {EVENT.TAGSJSON} and {EVENT.RECOVERY.TAGSJSON} built-in macros (these macros will resolve to a JSON array containing event tag **objects** or recovery event tag objects)

Substring extraction in trigger tags

Substring extraction is supported for populating the tag name or tag value, using a macro **function**. The function applies a regular expression to the value obtained by the **supported** macro. For example:

```
{{ITEM.VALUE}.regsub(pattern, output)}
{{ITEM.VALUE}.iregsub(pattern, output)}
```

```
{{#LLDMACRO}.regsub(pattern, output)}
{{#LLDMACRO}.iregsub(pattern, output)}
```

If the tag name or value exceeds 255 characters after macro resolution, it will be truncated to 255 characters.

See also: Using macro functions in **low-level discovery macros** for event tagging.

Viewing event tags

Tags, if defined, can be viewed with new events in:

- *Monitoring* → **Problems**
- *Monitoring* → **Problems** → **Event details**
- *Dashboards* → **Problems widget**

The order and number of displayed tags is determined by the *Tag display priority* and *Show tags* filtering options in *Monitoring* → *Problems* or the *Problems* dashboard widget. Note that a maximum of three tags can be displayed; if there are more tags, hovering over the three dots reveals all tags in a pop-up window.

7 Visualization

Please use the sidebar to access content in the Visualization section.

1 Graphs

Overview

With lots of data flowing into Zabbix, it becomes much easier for the users if they can look at a visual representation of what is going on rather than only numbers.

This is where graphs come in. Graphs allow to grasp the data flow at a glance, correlate problems, discover when something started or make a presentation of when something might turn into a problem.

Zabbix provides users with:

- built-in **simple graphs** of one item data
- the possibility to create more complex **customized graphs**
- access to a comparison of several items quickly in **ad-hoc graphs**
- modern customizable vector **graphs** and **pie charts**

1 Simple graphs

Overview

Simple graphs are provided for the visualization of data gathered by items.

No configuration effort is required on the user part to view simple graphs. They are freely made available by Zabbix.

Just go to *Monitoring* → *Latest data* and click on the Graph link for the respective item and a graph will be displayed.

Data from history. Generated in 0.12 sec.

Note:

Simple graphs are provided for all numeric items. For textual items, a link to History is available in *Monitoring → Latest data*.

Time period selector

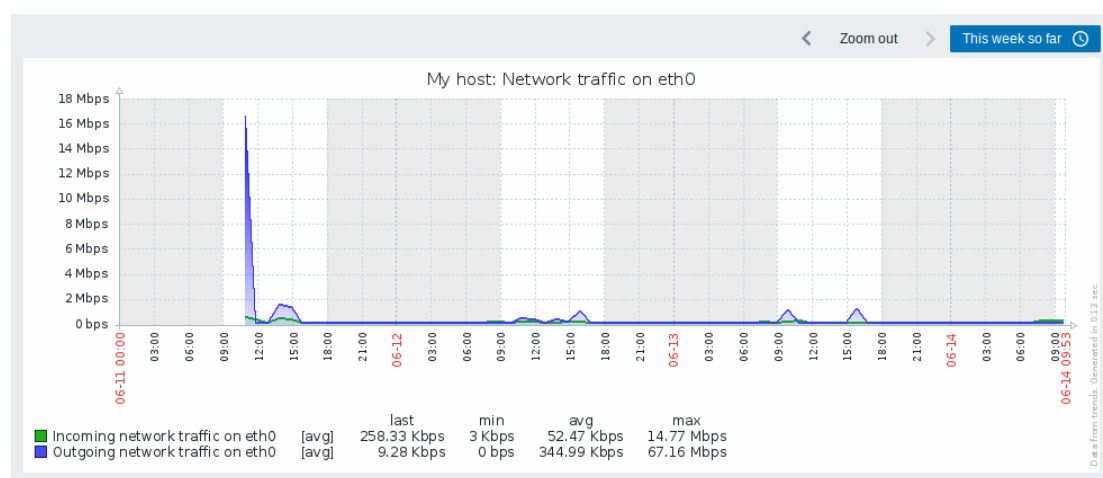

The *Time period* selector above the graph allows to select often required periods with one mouse click. For more information, see [Time period selector](#).

Recent data vs longer periods

For very recent data a **single** line is drawn connecting each received value. The single line is drawn as long as there is at least one horizontal pixel available for one value.

For data that show a longer period **three lines** are drawn - a dark green one shows the average, while a light pink and a light green line shows the maximum and minimum values at that point in time. The space between the highs and the lows is filled with yellow background.

Working time (working days) is displayed in graphs as a white background, while non-working time is displayed in gray (with the *Original blue* default frontend theme).

Working time is always displayed in simple graphs, whereas displaying it in **custom graphs** is a user preference.

Working time is not displayed if the graph shows more than 3 months.

Trigger lines

Simple triggers are displayed as lines with black dashes over trigger severity color -- take note of the blue line on the graph and the trigger information displayed in the legend. Up to 3 trigger lines can be displayed on the graph; if there are more triggers then the triggers with lower severity are prioritized. Triggers are always displayed in simple graphs, whereas displaying them in **custom graphs** is a user preference.

Generating from history/trends

Graphs can be drawn based on either item **history** or **trends**.

For the users who have frontend **debug mode** activated, a gray, vertical caption is displayed at the bottom right of a graph indicating where the data come from.

Several factors influence whether history of trends is used:

- longevity of item history. For example, item history can be kept for 14 days. In that case, any data older than the fourteen days will be coming from trends.
- data congestion in the graph. If the amount of seconds to display in a horizontal graph pixel exceeds 3600/16, trend data are displayed (even if item history is still available for the same period).
- if trends are disabled, item history is used for graph building - if available for that period.

Absence of data

For items with a regular update interval, nothing is displayed in the graph if item data are not collected.

However, for trapper items and items with a scheduled update interval (and regular update interval set to 0), a straight line is drawn leading up to the first collected value and from the last collected value to the end of graph; the line is on the level of the first/last value respectively.

Switching to raw values

A dropdown on the upper right allows to switch from the simple graph to the *Values/500 latest values* listings. This can be useful for viewing the numeric values making up the graph.

The values represented here are raw, i.e. no units or postprocessing of values is used. Value mapping, however, is applied.

Known issues

See **known issues** for graphs.

2 Custom graphs

Overview

Custom graphs, as the name suggests, offer customization capabilities.

While simple graphs are good for viewing data of a single item, they do not offer configuration capabilities.

| Parameter | Description |
|--------------------------------|---|
| <i>Show working time</i> | If selected, non-working hours will be shown with a gray background. This parameter is not available for pie and exploded pie graphs. |
| <i>Show triggers</i> | If selected, simple triggers will be displayed as lines with black dashes over trigger severity color. This parameter is not available for pie and exploded pie graphs. |
| <i>Percentile line (left)</i> | Display percentile for left Y-axis. If, for example, 95% percentile is set, then the percentile line will be at the level where 95 percent of the values fall under. Displayed as a bright green line. Only available for normal graphs. |
| <i>Percentile line (right)</i> | Display percentile for right Y-axis. If, for example, 95% percentile is set, then the percentile line will be at the level where 95 percent of the values fall under. Displayed as a bright red line. Only available for normal graphs. |
| <i>Y axis MIN value</i> | Minimum value of Y-axis: Calculated - Y axis minimum value will be automatically calculated. Fixed - fixed minimum value for Y-axis. Item - last value of the selected item will be the minimum value. |
| <i>Y axis MAX value</i> | This parameter is not available for pie and exploded pie graphs. Maximum value of Y-axis: Calculated - Y axis maximum value will be automatically calculated. Fixed - fixed maximum value for Y-axis. Item - last value of the selected item will be the maximum value |
| <i>3D view Items</i> | This parameter is not available for pie and exploded pie graphs. Enable 3D style. For pie and exploded pie graphs only. |
| <i>Sort order (0→100)</i> | Items, data of which are to be displayed in this graph. Click on <i>Add</i> to select items. You can also select various displaying options (function, draw style, left/right axis display, color). Draw order. 0 will be processed first. Can be used to draw lines or regions behind (or in front of) another. You can drag and drop items using the icon at the beginning of a line to set the sort order or which item is displayed in front of the other. |
| <i>Name</i> | Name of the selected item is displayed as a link. Clicking on the link opens the list of other available items. |
| <i>Type</i> | Type (only available for pie and exploded pie graphs): Simple - the value of the item is represented proportionally on the pie Graph sum - the value of the item represents the whole pie Note that coloring of the "graph sum" item will only be visible to the extent that it is not taken up by "proportional" items. |
| <i>Function</i> | Select what values will be displayed when more than one value exists per vertical graph pixel for an item: all - display all possible values (minimum, maximum, average) in the graph. Note that for shorter periods this setting has no effect; only for longer periods, when data congestion in a vertical graph pixel increases, 'all' starts displaying minimum, maximum, and average values. This function is only available for <i>Normal</i> graph type. See also: Generating graphs from history/trends . avg - display the average values last - display the latest values. This function is only available if either <i>Pie/Exploded pie</i> is selected as graph type. max - display the maximum values min - display the minimum values |
| <i>Draw style</i> | Select the draw style (only available for normal graphs; for stacked graphs filled region is always used) to apply to the item data - <i>Line, Bold line, Filled region, Dot, Dashed line, Gradient line</i> . |
| <i>Y axis side Color</i> | Select the Y axis side to show the item data - <i>Left, Right</i> . Select the color to apply to the item data. |

Graph preview

In the *Preview* tab, a preview of the graph is displayed so you can immediately see what you are creating.

Note that the preview will not show any data for template items.

In this example, pay attention to the dashed bold line displaying the trigger level and the trigger information displayed in the legend.

Note:

No more than 3 trigger lines can be displayed. If there are more triggers then the triggers with lower severity are prioritized for display.

If graph height is set as less than 120 pixels, no trigger will be displayed in the legend.

3 Ad-hoc graphs

Overview

While a **simple graph** is great for accessing data of one item and **custom graphs** offer customization options, none of the two allow to quickly create a comparison graph for multiple items with little effort and no maintenance.

To address this issue, it is possible to create ad-hoc graphs for several items in a very quick way.

Configuration

To create an ad-hoc graph, do the following:

- Go to **Monitoring** → **Latest data**
- Use filter to display items that you want
- Mark checkboxes of the items you want to graph

- Click on *Display stacked graph* or *Display graph* buttons

Latest data

| <input type="checkbox"/> Host ▲ | Name | Last check | Last value |
|---|------------------------|-----------------------|------------|
| <input checked="" type="checkbox"/> New host | CPU load average | 05/24/2021 10:46:5... | 0.86 |
| <input type="checkbox"/> Zabbix server | Load average (1m avg) | 05/24/2021 10:47:1... | 0.73 |
| <input type="checkbox"/> Zabbix server | Load average (15m avg) | 05/24/2021 10:47:1... | 0.93 |
| <input checked="" type="checkbox"/> Zabbix server | Load average (5m avg) | 05/24/2021 10:47:1... | 0.93 |

2 selected

[Display stacked graph](#)
[Display graph](#)

Your graph is created instantly:

Note that to avoid displaying too many lines in the graph, only the average value for each item is displayed (min/max value lines are not displayed). Triggers and trigger information is not displayed in the graph.

In the created graph window you have the *Time period selector* available and the possibility to switch from the "normal" line graph to a stacked one (and back).

4 Aggregation in graphs

Overview

Aggregation functions, available in the graph and pie chart widgets of the dashboard, allow displaying an aggregated value for the chosen interval (5 minutes, an hour, a day), instead of all values.

This section provides more detail on aggregation options in the graph widget.

The aggregation options are as follows:

- min
- max
- avg
- count
- sum
- first (first value displayed)
- last (last value displayed)

The most exciting use of data aggregation is the possibility to create nice side-by-side comparisons of data for some period:

When hovering over a point in time in the graph, date and time is displayed in addition to items and their aggregated values. Items are displayed in parentheses, prefixed by the aggregation function used. If the graph widget has a *Data set label* configured, the label is displayed in parentheses, prefixed by the aggregation function used. Note that this is the date and time of the point in the graph, not of the actual values.

Configuration

The options for aggregation are available in data set settings when configuring a *graph widget*.

Y-axis

Time shift

Aggregation function

Aggregation interval

Aggregate

Approximation

Data set label

You may pick the aggregation function and the time interval. As the data set may comprise several items, there is also another option allowing to show aggregated data for each item separately or for all data set items as one aggregated value.

Use cases

Average request count to Nginx server

View the average request count per second per day to the Nginx server:

- add the request count per second item to the data set
- select the aggregate function `avg` and specify interval `1d`
- a bar graph is displayed, where each bar represents the average number of requests per second per day

Minimum weekly disk space among clusters

View the lowest disk space among clusters over a week.

- add to the data set: hosts `cluster*`, key "Free disk space on /data"
- select the aggregate function `min` and specify interval `1w`
- a bar graph is displayed, where each bar represents the minimum disk space per week for each /data volume of the cluster

2 Network maps

Overview

If you have a network to look after, you may want to have an overview of your infrastructure somewhere. For that purpose, you can create maps in Zabbix - of networks and of anything you like.

All users can create network maps. The maps can be public (available to all users) or private (available to selected users).

Proceed to [configuring a network map](#).

1 Configuring a network map

Overview

Configuring a map in Zabbix requires that you first create a map by defining its general parameters and then you start filling the actual map with elements and their links.

You can populate the map with elements that are a host, a host group, a trigger, an image, or another map.

Icons are used to represent map elements. You can define the information that will be displayed with the icons and set that recent problems are displayed in a special way. You can link the icons and define information to be displayed on the links.

You can add custom URLs to be accessible by clicking on the icons. Thus you may link a host icon to host properties or a map icon to another map.

The problem count in maps is displayed for cause problems only.

Maps are managed in *Monitoring* → *Maps*, where they can be configured, managed and viewed. In the monitoring view, you can click on the icons and take advantage of the links to some scripts and URLs.

Network maps are based on vector graphics (SVG).

Public and private maps

All users in Zabbix (including non-admin users) can create network maps. Maps have an owner - the user who created them. Maps can be made public or private.

- *Public* maps are visible to all users, although to see it the user must have read access to at least one map element. Public maps can be edited in case a user/ user group has read-write permissions for this map and at least read permissions to all elements of the corresponding map including triggers in the links.
- *Private* maps are visible only to their owner and the users/user groups the map is *shared* with by the owner. Regular (non-Super admin) users can only share with the groups and users they are members of. Admin level users can see private maps regardless of being the owner or belonging to the shared user list. Private maps can be edited by the owner of the map and in case a user/ user group has read-write permissions for this map and at least read permissions to all elements of the corresponding map including triggers in the links.

Map elements that the user does not have read permission to are displayed with a grayed-out icon and all textual information on the element is hidden. However, the trigger label is visible even if the user has no permission to the trigger.

To add an element to the map the user must also have at least read permission to the element.

Creating a map

To create a map, do the following:

- Go to *Monitoring* → *Maps*
- Go to the view with all maps
- Click on *Create map*

You can also use the *Clone* button in the configuration form of an existing map to create a new map. This map will have all of the properties of the existing map, including general layout attributes, as well as the elements of the existing map.

The **Map** tab contains general map attributes:

Map

All mandatory input fields are marked with a red asterisk.

General map attributes:

| Parameter | Description |
|---|---|
| <i>Owner</i> | Name of map owner. |
| <i>Name</i> | Unique map name. |
| <i>Width</i> | Map width in pixels. |
| <i>Height</i> | Map height in pixels. |
| <i>Background image</i> | Use background image: No image - no background image (white background) Image - selected image to be used as a background image. No scaling is performed. You may use a geographical map or any other image to enhance your map. |
| <i>Automatic icon mapping</i> | You can set to use an automatic icon mapping, configured in <i>Administration</i> → <i>General</i> → <i>Icon mapping</i> . Icon mapping allows mapping certain icons against certain host inventory fields. |
| <i>Icon highlight</i> | If you check this box, map elements will be highlighted. Elements with an active trigger will receive a round background, in the same color as the highest severity trigger. Moreover, a thick green line will be displayed around the circle, if all problems are acknowledged. Elements with "disabled" or "in maintenance" status will get a square background, gray and orange respectively. See also: Viewing maps |
| <i>Mark elements on trigger status change</i> | A recent change of trigger status (recent problem or resolution) will be highlighted with markers (inward-pointing red triangles) on the three sides of the element icon that are free of the label. Markers are displayed for 30 minutes. |
| <i>Display problems</i> | Select how problems are displayed with a map element: Expand single problem - if there is only one problem, the problem name is displayed. Otherwise, the total number of problems is displayed. Number of problems - the total number of problems is displayed Number of problems and expand most critical one - the name of the most critical problem and the total number of problems is displayed. 'Most critical' is determined based on problem severity and, if equal, problem event ID (higher ID or later problem displayed first). For a <i>trigger map element</i> it is based on problem severity and if equal, trigger position in the trigger list. In case of multiple problems of the same trigger, the most recent one will be displayed. |
| <i>Advanced labels</i> | If you check this box you will be able to define separate label types for separate element types. |
| <i>Map element label type</i> | Label type used for map elements: Label - map element label IP address - IP address Element name - element name (for example, host name) Status only - status only (OK or PROBLEM) Nothing - no labels are displayed |
| <i>Map element label location</i> | Label location in relation to the map element: Bottom - beneath the map element Left - to the left Right - to the right Top - above the map element |
| <i>Problem display</i> | Display problem count as: All - full problem count will be displayed Separated - unacknowledged problem count will be displayed separated as a number of the total problem count Unacknowledged only - only the unacknowledged problem count will be displayed |
| <i>Minimum trigger severity</i> | Problems below the selected minimum severity level will not be displayed on the map. For example, with <i>Warning</i> selected, changes with <i>Information</i> and <i>Not classified</i> level triggers will not be reflected in the map. |
| <i>Show suppressed problems</i> | Mark the checkbox to display problems that would otherwise be suppressed (not shown) because of host maintenance. |
| <i>URLs</i> | URLs (up to 2048 characters) for each element type can be defined. A label for the URL can also be defined. These will be displayed as links when a user clicks on the element in the map viewing mode. Macros can be used in map URL names and values. For a full list, see supported macros and search for 'map URL names and values'. |

Sharing

The **Sharing** tab contains the map type as well as sharing options (user groups, users) for private maps:

Map
Sharing ●

Type
Private Public

List of user group shares

User groups
MySQL administrators
Add
Permissions
Read-only Read-write

List of user shares

Users
Admin (Zabbix Administrator)
Add
Permissions
Read-only Read-write

| Parameter | Description |
|---------------------------|---|
| Type | Select map type: Private - map is visible only to selected user groups and users Public - map is visible to all |
| List of user group shares | Select user groups that the map is accessible to. You may allow read-only or read-write access. |
| List of user shares | Select users that the map is accessible to. You may allow read-only or read-write access. |

When you click on *Add* to save this map, you have created an empty map with a name, dimensions, and certain preferences. Now you need to add some elements. For that, click on *Edit* in the map list to open the editable area.

Adding elements

To add an element, click on *Add* next to Map element. The new element will appear at the top left corner of the map. Drag and drop it wherever you like.

Note that with the Grid option "On", elements will always align to the grid (you can pick various grid sizes from the dropdown, also hide/show the grid). If you want to put elements anywhere without alignment, turn the option to "Off". (You can align random elements to the grid later, by clicking on *Align map elements*.)

Now that you have some elements in place, you may want to start differentiating them by giving names, etc. By clicking on the element, a form is displayed and you can set the element type, give a name, choose a different icon, etc.

| Parameter | Description |
|---------------------------------|---|
| <i>Triggers</i> | <p>If the element type is 'Trigger', select one or more triggers in the <i>New triggers</i> field below and click on <i>Add</i>.</p> <p>The order of selected triggers can be changed, but only within the same severity of triggers. Multiple trigger selection also affects {HOST.*} macro resolution both in the editing and view modes.</p> <p>// 1 In editing mode// the first displayed {HOST.*} macros will be resolved depending on the first trigger in the list (based on trigger severity).</p> <p>// 2 View mode// depends on the Display problems parameter in General map attributes.</p> <p>* If <i>Expand single problem</i> mode is chosen, the first displayed {HOST.*} macros will be resolved depending on the latest detected problem trigger (not mattering the severity) or the first trigger in the list (in case no problem detected);</p> <p>* If <i>Number of problems and expand most critical one</i> mode is chosen, the first displayed {HOST.*} macros will be resolved depending on the trigger severity.</p> |
| <i>Host group</i> | <p>Enter the host group if the element type is 'Host group'. This field is auto-complete so starting to type the name of a group will offer a dropdown of matching groups. Scroll down to select. Click on 'x' to remove the selected.</p> |
| <i>Tags</i> | <p>Specify tags to limit the number of problems displayed in the widget. It is possible to include as well as exclude specific tags and tag values. Several conditions can be set. Tag name matching is always case-sensitive.</p> <p>There are several operators available for each condition:</p> <p>Exists - include the specified tag names</p> <p>Equals - include the specified tag names and values (case-sensitive)</p> <p>Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive)</p> <p>Does not exist - exclude the specified tag names</p> <p>Does not equal - exclude the specified tag names and values (case-sensitive)</p> <p>Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive)</p> <p>There are two calculation types for conditions:</p> <p>And/Or - all conditions must be met, conditions having the same tag name will be grouped by the Or condition</p> <p>Or - enough if one condition is met</p> <p>This field is available for host and host group element types.</p> |
| <i>Automatic icon selection</i> | <p>In this case an icon mapping will be used to determine which icon to display.</p> |
| <i>Icons</i> | <p>You can choose to display different icons for the element in these cases: default, problem, maintenance, disabled.</p> |
| <i>Coordinate X</i> | X coordinate of the map element. |
| <i>Coordinate Y</i> | Y coordinate of the map element. |
| <i>URLs</i> | <p>Element-specific URLs (up to 2048 characters) can be set for the element. A label for the URL can also be defined. These will be displayed as links when a user clicks on the element in the map viewing mode. If the element has its own URLs and there are map level URLs for its type defined, they will be combined in the same menu.</p> <p>Macros can be used in map element names and values. For a full list, see supported macros and search for 'map URL names and values'.</p> |

Attention:

Added elements are not automatically saved. If you navigate away from the page, all changes may be lost. Therefore it is a good idea to click on the **Update** button in the top right corner. Once clicked, the changes are saved regardless of what you choose in the following popup. Selected grid options are also saved with each map.

Selecting elements

To select elements, select one and then hold down *Ctrl* to select the others.

You can also select multiple elements by dragging a rectangle in the editable area and selecting all elements in it.

Once you select more than one element, the element property form shifts to the mass-update mode so you can change attributes of selected elements in one go. To do so, mark the attribute using the checkbox and enter a new value for it. You may use macros here (for example, {HOST.NAME} for the element label).

Linking elements

Once you have put some elements on the map, it is time to start linking them. To link two elements you must first select them. With the elements selected, click on *Add* next to Link.

With a link created, the single element form now contains an additional *Links* section. Click on *Edit* to edit link attributes.

Link attributes:

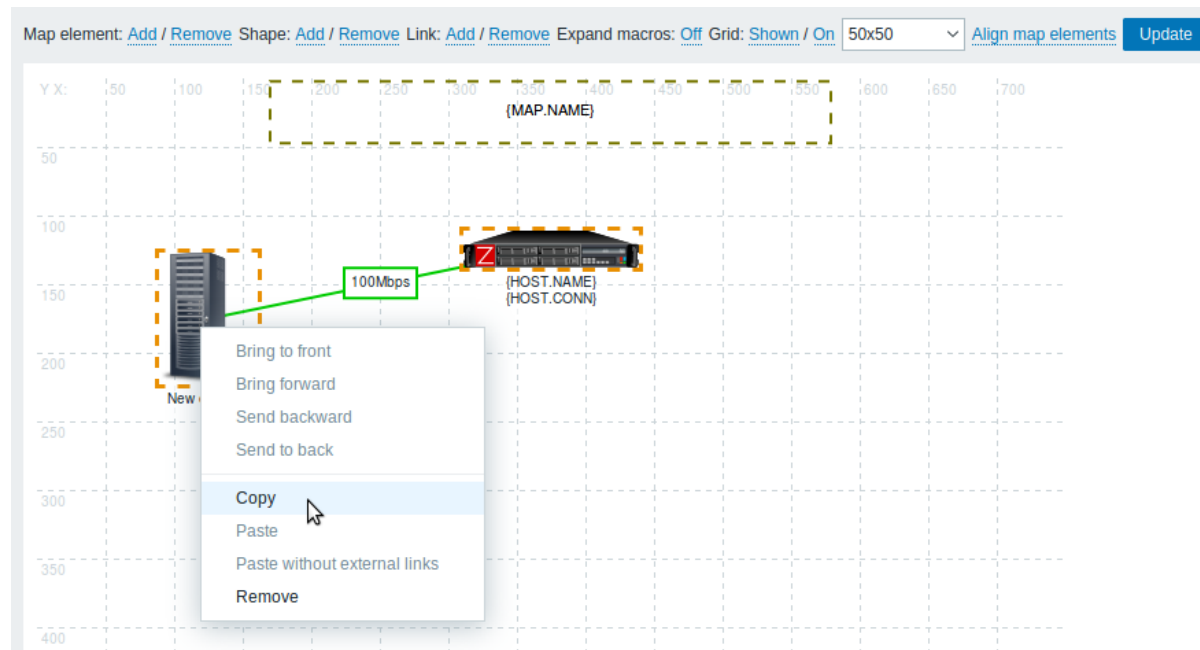

| Parameter | Description |
|-------------------|---|
| <i>Label</i> | Label that will be rendered on top of the link. Expression macros are supported in this field, but only with <code>avg</code> , <code>last</code> , <code>min</code> and <code>max</code> functions, with time as parameter (for example, <code>{?avg(/host/key, 1h)}</code>). |
| <i>Connect to</i> | The element that the link connects to. |

| Parameter | Description |
|-----------------|---|
| Type (OK) | Default link style: Line - single line Bold line - bold line Dot - dots Dashed line - dashed line |
| Color (OK) | Default link color. |
| Link indicators | List of triggers linked to the link. In case a trigger has status PROBLEM, its style is applied to the link. |

Moving and copy-pasting elements

Several selected elements can be **moved** to another place in the map by clicking on one of the selected elements, holding down the mouse button, and moving the cursor to the desired location.

One or more elements can be **copied** by selecting the elements, then clicking on a selected element with the right mouse button and selecting *Copy* from the menu.

To paste the elements, click on a map area with the right mouse button and select *Paste* from the menu. The *Paste without external links* option will paste the elements retaining only the links that are between the selected elements.

Copy-pasting works within the same browser window. Keyboard shortcuts are not supported.

Adding shapes

In addition to map elements, it is also possible to add some shapes. Shapes are not map elements; they are just a visual representation. For example, a rectangle shape can be used as a background to group some hosts. Rectangle and ellipse shapes can be added.

To add a shape, click on *Add* next to Shape. The new shape will appear at the top left corner of the map. Drag and drop it wherever you like.

A new shape is added with default colors. By clicking on the shape, a form is displayed and you can customize the way a shape looks, add text, etc.

To select shapes, select one and then hold down **Ctrl** to select the others. With several shapes selected, common properties can be mass updated, similarly as with elements.

Text can be added in the shapes. Expression **macros** are supported in the text, but only with **avg**, **last**, **min** and **max** functions, with time as parameter (for example, `{?avg(/host/key,1h)}`).

To display text only, the shape can be made invisible by removing the shape border (select 'None' in the *Border* field). For example, take note of how the `{MAP.NAME}` macro, visible in the screenshot above, is actually a rectangle shape with text, which can be seen when clicking on the macro:

`{MAP.NAME}` resolves to the configured map name when viewing the map.

If hyperlinks are used in the text, they become clickable when viewing the map.

Line wrapping for text is always "on" within shapes. However, within an ellipse, the lines are wrapped as though the ellipse were a rectangle. Word wrapping is not implemented, so long words (words that do not fit the shape) are not wrapped, but are masked

(on map editing page) or clipped (other pages with maps).

Adding lines

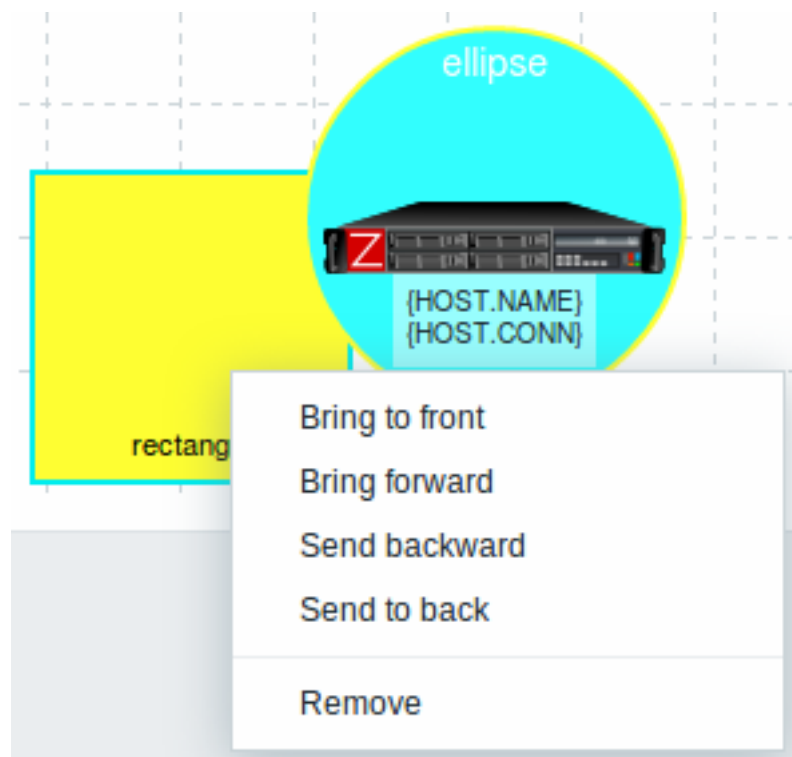

In addition to shapes, it is also possible to add some lines. Lines can be used to link elements or shapes in a map.

To add a line, click on *Add* next to Shape. A new shape will appear at the top left corner of the map. Select it and click on *Line* in the editing form to change the shape into a line. Then adjust line properties, such as line type, width, color, etc.

Ordering shapes and lines

To bring one shape in front of the other (or vice versa) click on the shape with the right mouse button bringing up the map shape menu.

2 Host group elements

Overview

This section explains how to add a “Host group” type element when configuring a **network map**.

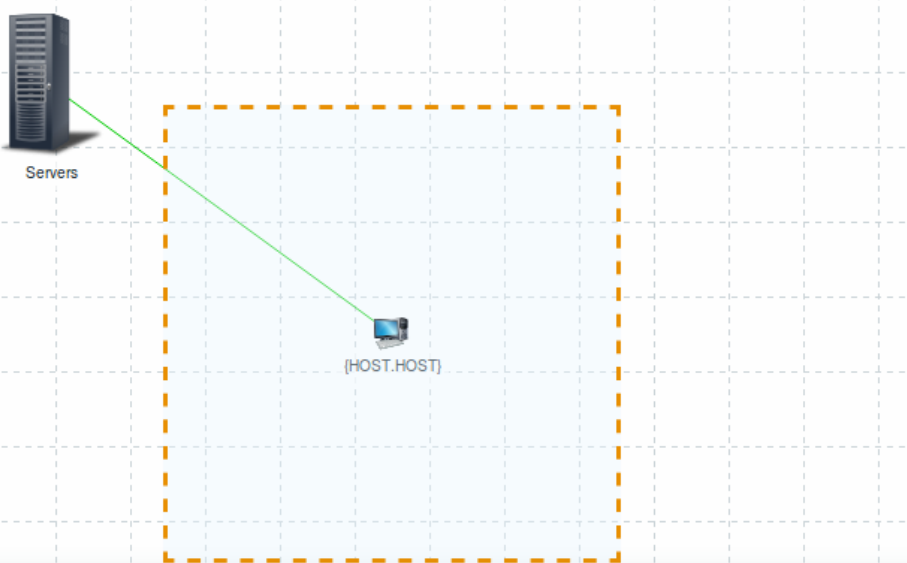

Configuration

Map element: [Add](#) / [Remove](#) Shape: [Add](#) / [Remove](#) Link: [Add](#) / [Remove](#) Expand macros: [Off](#) Grid: [Shown](#) / [On](#) 50x50 [Align map elements](#)

Y X: 50 100 150 200 250 300 350 400

Local network 2

50 100 150 200 250 300 350 400

Map element

Type Host group

Show Host group Host group elements

Area type Fit to map Custom size

Area size Width 300 Height 300

Placing algorithm Grid

Label {HOST.HOST}

Label location Default

* Host group Linux servers Select

Application Select

All mandatory input fields are marked with a red asterisk.

This table consists of parameters typical for *Host group* element type:

| Parameter | Description |
|-----------|--|
| Type | Select Type of the element: Host group - icon representing the status of all triggers of all hosts belonging to the selected group |
| Show | Show options: Host group - selecting this option will result as one single icon displaying corresponding information about the certain host group Host group elements - selecting this option will result as multiple icons displaying corresponding information about every single element (host) of the certain host group |

405

| Parameter | Description |
|-------------------|---|
| Area type | This setting is available if the “Host group elements” parameter is selected: Fit to map - all host group elements are equally placed within the map Custom size - a manual setting of the map area for all the host group elements to be displayed |
| Area size | This setting is available if “Host group elements” parameter and “Area type” parameter are selected: Width - numeric value to be entered to specify map area width Height - numeric value to be entered to specify map area height |
| Placing algorithm | Grid - only available option of displaying all the host group elements |
| Label | Icon label, any string. Macros and multiline strings can be used in labels. If the type of the map element is “Host group” specifying certain macros has an impact on the map view displaying corresponding information about every single host. For example, if {HOST.IP} macro is used, the edit map view will only display the macro {HOST.IP} itself while map view will include and display each host’s unique IP address |

Viewing host group elements

This option is available if the “Host group elements” show option is chosen. When selecting “Host group elements” as the *show* option, you will at first see only one icon for the host group. However, when you save the map and then go to the map view, you will see that the map includes all the elements (hosts) of the certain host group:

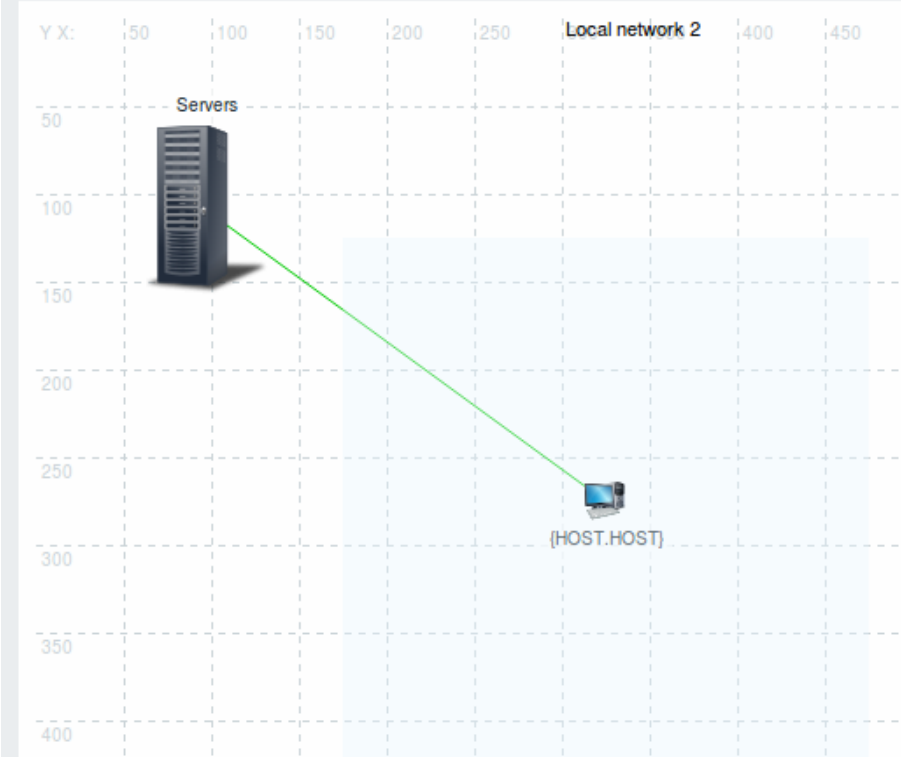

Map editing view

≡ Network maps

Map element: [Add](#) / [Remove](#) Shape: [Add](#) / [Remove](#) Link: [Add](#) / [Remove](#) Expand macros: [On](#)

Y X: 50 100 150 200 250 300 350 400

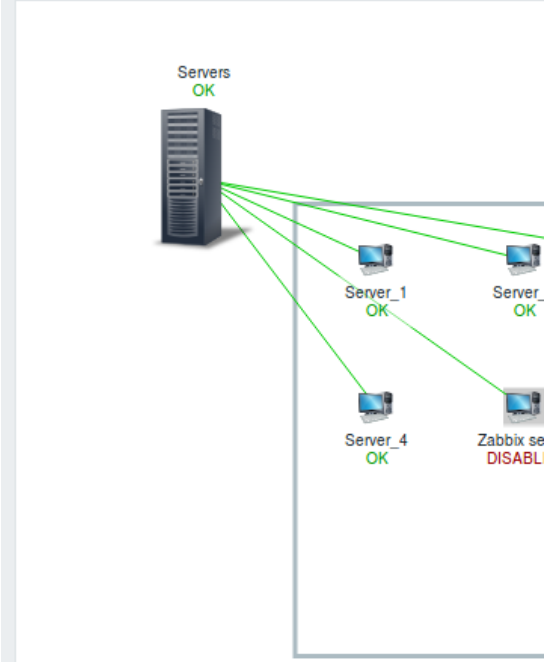

Local network 2 400 450

Map view

≡ Maps

[All maps](#) / [Local network 2](#)

Notice how the {HOST.HOST} macro is used. In map editing, the macro name is unresolved, while in map view all the unique names of the hosts are displayed.

3 Link indicators

Overview

You can assign some triggers to a **link** between elements in a network map. When these triggers go into a problem state, the link can reflect that.

406

When you configure a link, you set the default link type and color. When you assign triggers to a link, you can assign different link types and colors with these triggers.

Should any of these triggers go into a problem state, their link style and color will be displayed on the link. So maybe your default link was a green line. Now, with the trigger in the problem state, your link may become bold red (if you have defined it so).

Configuration

To assign triggers as link indicators, do the following:

- select a map element
- click on *Edit* in the *Links* section for the appropriate link
- click on *Add* in the *Link indicators* block and select one or more triggers

Network maps

Links

| Element name | Link indicators |
|---------------|--|
| Zabbix server | New host (former tech name: Server4): Trap trigger |

Label:

Connect to: Zabbix server ▼

Type (OK): Bold line ▼

Color (OK): 00CC00 ▼

Link indicators

| Trigger | Type | Color |
|--|----------------------------------|------------------------------------|
| New host (former tech name: Server4): Trap trigger | Line ▼ | DD0000 ▼ |

[Add](#)

Apply Remove Close

All mandatory input fields are marked with a red asterisk.

Added triggers can be seen in the *Link indicators* list.

You can set the link type and color for each trigger directly from the list. When done, click on *Apply*, close the form and click on *Update* to save the map changes.

Display

In *Monitoring* → *Maps* the respective color will be displayed on the link if the trigger goes into a problem state.

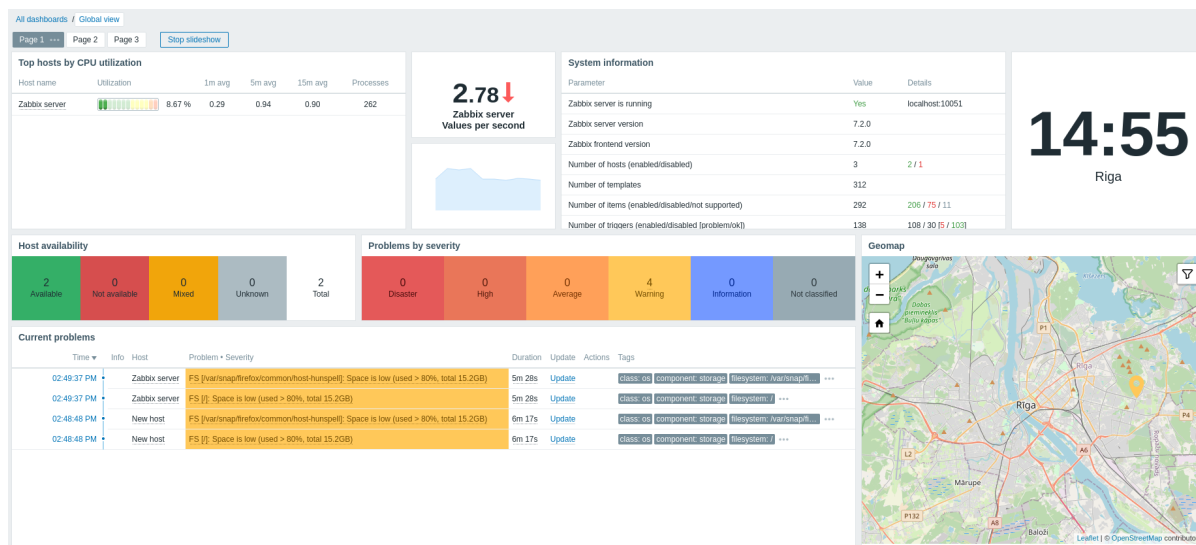

Note:

If multiple triggers go into a problem state, the problem with the highest severity will determine the link style and color. If multiple triggers with the same severity are assigned to the same map link, the one with the lowest ID takes precedence. Note also that:

1. *Minimum trigger severity* and *Show suppressed problem* settings from map configuration affect which problems are taken into account.
2. In the case of triggers with multiple problems (multiple problem generation), each problem may have a severity that differs from trigger severity (changed manually), may have different tags (due to macros), and may be suppressed.

3 Dashboards

Dashboards - both **global dashboards** and **host dashboards** - provide a strong visualization platform with such **widgets** and tools as modern graphs, maps, slideshows, and more.

8 Templates and template groups

Overview

The use of templates is an excellent way of reducing one's workload and streamlining the Zabbix configuration. A template is a set of entities that can be conveniently applied to multiple hosts.

The entities may be:

- items
- triggers
- graphs
- dashboards
- low-level discovery rules
- web scenarios

As many hosts in real life are identical or fairly similar so it naturally follows that the set of entities (items, triggers, graphs,...) you have created for one host, may be useful for many. Of course, you could copy them to each new host, but that would be a lot of manual work. Instead, with templates you can copy them to one template and then apply the template to as many hosts as needed.

When a template is linked to a host, all entities (items, triggers, graphs,...) of the template are added to the host. Templates are assigned to each individual host directly (and not to a host group).

Templates are often used to group entities for particular services or applications (like Apache, MySQL, PostgreSQL, Postfix...) and then applied to hosts running those services.

Another benefit of using templates is when something has to be changed for all the hosts. Changing something on the template level once will propagate the change to all the linked hosts.

Templates are organized in [template groups](#).

Proceed to [creating and configuring a template](#).

9 Templates out of the box

Overview

Zabbix strives to provide a growing list of useful out-of-the-box [templates](#). Out-of-the-box templates come preconfigured and thus are a useful way for speeding up the deployment of monitoring jobs.

The templates are available:

- In new installations - in *Data collection* → *Templates*;
- If you are upgrading Zabbix, the upgraded installation might lack newer templates. You can find them in the Zabbix [Git repository](#) - select the version you upgraded to. To add a new template, download the template file, open Zabbix frontend, go to *Data collection* → *Templates*, and import the file.

Please use the sidebar to access information about specific template types and operation requirements.

See also:

- [Template import](#)
- [Linking a template](#)
- [Known issues](#)

1 Zabbix agent template operation

Steps to ensure correct operation of templates that collect metrics with [Zabbix agent](#):

1. Make sure that Zabbix agent is installed on the host. For active checks, also make sure that the host is added to the 'ServerActive' parameter of the agent [configuration file](#).
2. [Link](#) the template to a target host (if the template is not available in your Zabbix installation, you may need to import the template's .xml file first - see [Templates out-of-the-box](#) section for instructions).
3. If necessary, adjust the values of template macros.
4. Configure the instance being monitored to allow sharing data with Zabbix.

A detailed description of a template, including the full list of macros, items and triggers is available in the template's Readme.md file (accessible by clicking on a template name).

The following templates are available:

- [Apache by Zabbix agent](#)
- [Apache by Zabbix agent active](#)
- [HAProxy by Zabbix agent](#)
- [IIS by Zabbix agent](#)
- [IIS by Zabbix agent active](#)
- [Microsoft Exchange Server 2016 by Zabbix agent](#)
- [Microsoft Exchange Server 2016 by Zabbix agent active](#)
- [MySQL by Zabbix agent](#)
- [MySQL by Zabbix agent active](#)
- [Nginx by Zabbix agent](#)
- [Nginx by Zabbix agent active](#)
- [PHP-FPM by Zabbix agent](#)
- [PHP-FPM by Zabbix agent active](#)
- [PostgreSQL by Zabbix agent](#)
- [PostgreSQL by Zabbix agent active](#)
- [RabbitMQ cluster by Zabbix agent](#)

2 Zabbix agent 2 template operation

Steps to ensure correct operation of templates that collect metrics with **Zabbix agent 2**:

1. Make sure that the agent 2 is installed on the host, and that the installed version contains the required plugin. In some cases, you may need to [upgrade](#) the agent 2 first.
2. [Link](#) the template to a target host (if the template is not available in your Zabbix installation, you may need to import the template's import file first - see [Templates out-of-the-box](#) section for instructions).
3. If necessary, adjust the values of template macros. Note that user macros can be used to override configuration parameters.
4. Configure the instance being monitored to allow sharing data with Zabbix.

Attention:

Zabbix agent 2 templates work in conjunction with the plugins. While the basic configuration can be done by simply adjusting user macros, the deeper customization can be achieved by [configuring the plugin](#) itself. For example, if a plugin supports named sessions, it is possible to monitor several entities of the same kind (e.g. MySQL1 and MySQL2) by specifying named session with own URI, username and password for each entity in the configuration file.

A detailed description of a template, including the full list of macros, items and triggers is available in the template's Readme.md file (accessible by clicking on a template name).

The following templates are available:

- [Ceph by Zabbix agent 2](#)
- [Docker](#)
- [Memcached](#)
- [MongoDB cluster by Zabbix agent 2](#)
- [MongoDB node by Zabbix agent 2](#)
- [MySQL by Zabbix agent 2](#)
- [MySQL by Zabbix agent 2 active](#)
- [Oracle by Zabbix agent 2](#)
- [PostgreSQL by Zabbix agent 2](#)
- [PostgreSQL by Zabbix agent 2 active](#)
- [Redis](#)
- [SMART by Zabbix agent 2](#)
- [SMART by Zabbix agent 2 active](#)
- [Systemd by Zabbix agent 2](#)
- [Website certificate by Zabbix agent 2](#)

3 HTTP template operation

Steps to ensure correct operation of templates that collect metrics with **HTTP agent**:

1. Create a host in Zabbix and specify an IP address or DNS name of the monitoring target as the main interface. This is needed for the {HOST.CONN} macro to resolve properly in the template items.
2. [Link](#) the template to the host created in step 1 (if the template is not available in your Zabbix installation, you may need to import the template's .xml file first - see [Templates out-of-the-box](#) section for instructions).
3. If necessary, adjust the values of template macros.
4. Configure the instance being monitored to allow sharing data with Zabbix.

A detailed description of a template, including the full list of macros, items and triggers is available in the template's Readme.md file (accessible by clicking on a template name).

The following templates are available:

- [Acronis Cyber Protect Cloud by HTTP](#)
- [Apache by HTTP](#)
- [Asterisk by HTTP](#)
- [AWS by HTTP](#)
- [AWS Cost Explorer by HTTP](#)
- [AWS EC2 by HTTP](#)

- [Veeam Backup and Replication by HTTP](#)
- [VMware SD-WAN VeloCloud by HTTP](#)
- [YugabyteDB by HTTP](#)
- [ZooKeeper by HTTP](#)

4 IPMI template operation

IPMI templates do not require any specific setup. To start monitoring, [link](#) the template to a target host (if the template is not available in your Zabbix installation, you may need to import the template's .xml file first - see [Templates out-of-the-box](#) section for instructions).

A detailed description of a template, including the full list of macros, items and triggers is available in the template's Readme.md file (accessible by clicking on a template name).

Available template:

- [Chassis by IPMI](#)

5 JMX template operation

Steps to ensure correct operation of templates that collect metrics by [JMX](#):

1. Make sure Zabbix [Java gateway](#) is installed and set up properly.
2. [Link](#) the template to the target host. The host should have JMX interface set up.

If the template is not available in your Zabbix installation, you may need to import the template's .xml file first - see [Templates out-of-the-box](#) section for instructions.

3. If necessary, adjust the values of template macros.
4. Configure the instance being monitored to allow sharing data with Zabbix.

A detailed description of a template, including the full list of macros, items and triggers is available in the template's Readme.md file (accessible by clicking on a template name).

The following templates are available:

- [Apache ActiveMQ by JMX](#)
- [Apache Cassandra by JMX](#)
- [Apache Kafka by JMX](#)
- [Apache Tomcat by JMX](#)
- [GridGain by JMX](#)
- [Ignite by JMX](#)

- [Jira Data Center by JMX](#)
- [WildFly Domain by JMX](#)
- [WildFly Server by JMX](#)

6 ODBC template operation

Steps to ensure correct operation of templates that collect metrics via **ODBC monitoring**:

1. Make sure that required ODBC driver is installed on Zabbix server or proxy.
2. [Link](#) the template to a target host (if the template is not available in your Zabbix installation, you may need to import the template's .xml file first - see [Templates out-of-the-box](#) section for instructions).
3. If necessary, adjust the values of template macros.
4. Configure the instance being monitored to allow sharing data with Zabbix.

A detailed description of a template, including the full list of macros, items and triggers is available in the template's Readme.md file (accessible by clicking on a template name).

The following templates are available:

- [MSSQL by ODBC](#)
- [MySQL by ODBC](#)
- [Oracle by ODBC](#)
- [PostgreSQL by ODBC](#)

7 Standardized templates for network devices

Overview

In order to provide monitoring for network devices such as switches and routers, we have created two so-called models: for the network device itself (its chassis basically) and for network interface.

Templates for many families of network devices are provided. All templates cover (where possible to get these items from the device):

- Chassis fault monitoring (power supplies, fans and temperature, overall status)
- Chassis performance monitoring (CPU and memory items)
- Chassis inventory collection (serial numbers, model name, firmware version)
- Network interface monitoring with IF-MIB and EtherLike-MIB (interface status, interface traffic load, duplex status for Ethernet)

These templates are available:

- In new installations - in *Data collection* → *Templates*;
- If you are upgrading from previous versions, you can find these templates in the *zabbix/templates* directory of the downloaded latest Zabbix version. While in *Data collection* → *Templates* you can import them manually from this directory.

If you are importing the new out-of-the-box templates, you may want to also update the `@Network` interfaces for discovery global regular expression to:

```
Result is FALSE: ^Software Loopback Interface
Result is FALSE: ^(?In)?[1L]oop[bB]ack[0-9._]*$
Result is FALSE: ^NULL[0-9._]*$
Result is FALSE: ^[1L]o[0-9._]*$
Result is FALSE: ^[sS]ystem$
Result is FALSE: ^Nu[0-9._]*$
```

to filter out loopbacks and null interfaces on most systems.

Devices

List of device families for which templates are available:

| Template name | Vendor | Device family | Known models | OS | MIBs used | Tags |
|---|---------|-----------------|-----------------|-------|--|-----------|
| <i>Alcatel Timetra</i> <i>TiMOS SNMP</i> | Alcatel | Alcatel Timetra | ALCATEL SR 7750 | TiMOS | TIMETRA-SYSTEM-MIB,TIMETRA-CHASSIS-MIB | Certified |

Template design

Templates were designed with the following in mind:

- User macros are used as much as possible so triggers can be tuned by the user;
- Low-level discovery is used as much as possible to minimize the number of unsupported items;
- All templates depend on Template ICMP Ping so all devices are also checked by ICMP;
- Items don't use any MIBs - SNMP OIDs are used in items and low-level discoveries. So it's not necessary to load any MIBs into Zabbix for templates to work;
- Loopback network interfaces are filtered when discovering as well as interfaces with ifAdminStatus = down(2)
- 64bit counters are used from IF-MIB::ifXTable where possible. If it is not supported, default 32bit counters are used instead.

All discovered network interfaces have a trigger that monitors its operational status (link), for example:

```
{$IFCONTROL:"{#IFNAME}"}=1 and last(/Alcatel Timetra TiMOS SNMP/net.if.status[ifOperStatus.{#SNMPINDEX}])
```

- If you do not want to monitor this condition for a specific interface create a user macro with context with the value 0. For example:

| Host macros | |
|-------------------------------------|-------|
| Macro | Value |
| <code>{\$IFCONTROL: "Gi0/0"}</code> | 0 |

where Gi0/0 is {#IFNAME}. That way the trigger is not used any more for this specific interface.

- You can also change the default behavior for all triggers not to fire and activate this trigger only to limited number of interfaces like uplinks:

Host
Templates
IPMI
Macros
Host inventory
Encryption

Host macros
Inherited and host macros

| Macro | Value |
|-----------------------|-------|
| {SIFCONTROL} | ⇒ 0 |
| {SIFCONTROL: "Gi0/0"} | ⇒ 1 |
| {SIFCONTROL: "Gi0/1"} | ⇒ 1 |

Tags

- Performance – device family MIBs provide a way to monitor CPU and memory items;
- Fault - device family MIBs provide a way to monitor at least one temperature sensor;
- Inventory – device family MIBs provide a way to collect at least the device serial number and model name;
- Certified – all three main categories above are covered.

8 VMware template operation

Overview

Zabbix includes a range of ready-to-use templates for **virtual machine monitoring**, designed for VMware vCenter and ESXi hypervisors. The available templates are contained in two separate template sets:

- **VMware** - uses UUID data for corresponding macros
- **VMware FQDN** - uses FQDN data for corresponding macros

The templates designed for monitoring VMware vCenter or ESXi hypervisors contain pre-configured low-level discovery rules along with various built-in checks for monitoring virtual installations.

Note:

For the correct functioning of the *VMware FQDN* template, each monitored virtual machine should have a unique OS name adhering to FQDN rules. Additionally, VMware Tools/Open Virtual Machine tools must be installed on every machine. If these prerequisites are met, using the *VMware FQDN* template is recommended. The *VMware FQDN* template has been available since Zabbix 5.2 with the introduction of the ability to create hosts with custom interfaces.

 A classic *VMware* template is also available and can be used if FQDN requirements are unmet. However, the *VMware* template has a known issue. Hosts for discovered virtual machines are created with names that are saved in vCenter (for example, "VM1", "VM2", etc.). If Zabbix agent is installed on these hosts, and active Zabbix agent autoregistration is enabled, the autoregistration process will read host names as they were registered during launch (for example, "vm1.example.com", "vm2.example.com", etc.). This can lead to the creation of new hosts for existing virtual machines (since no name matches have been found), resulting in duplicate hosts with different names.

Please note:

- The template *VMware Hypervisor* can be manually linked to a host as well as used in discovery;
- The template *VMware Guest* should not be manually linked to a host and can only be used in discovery.

Host macro configuration

To use VMware simple checks, the host must have the following user macros defined:

- {\$VMWARE.URL} - VMware service (vCenter or ESXi hypervisor) SDK URL (https://servername/sdk)
- {\$VMWARE.USERNAME} - VMware service user name
- {\$VMWARE.PASSWORD} - VMware service {\$VMWARE.USERNAME} user password

10 Notifications upon events

Overview

Assuming that we have configured some items and triggers and now are getting some events happening as a result of triggers changing state, it is time to consider some actions.

To begin with, we would not want to stare at the triggers or events list all the time. It would be much better to receive notification if something significant (such as a problem) has happened. Also, when problems occur, we would like to see that all the people concerned are informed.

That is why sending notifications is one of the primary actions offered by Zabbix. Who and when should be notified upon a certain event can be defined.

To be able to send and receive notifications from Zabbix you have to:

- **define some media**
- **configure an action** that sends a message to one of the defined media

Actions consist of *conditions* and *operations*. Basically, when conditions are met, operations are carried out. The two principal operations are sending a message (notification) and executing a remote command.

For discovery and autoregistration created events, some additional operations are available. Those include adding or removing a host, linking a template etc.

1 Media types

Overview

Media are the delivery channels used for sending notifications and alerts from Zabbix.

You can configure several media types:

- **Email**
- **SMS**
- **Custom alertscripts**
- **Webhook**

Media types are configured in *Alerts* → *Media types*.

Media types

Filter

Name Status **Any** Enabled Disabled Display actions **All** All available Specific **Apply** **Reset**

| <input type="checkbox"/> Name | Type | Status | Used in actions | Details | Action |
|---|---------|----------|---|--|--------|
| <input type="checkbox"/> Brevis.one | Webhook | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | | Test |
| <input type="checkbox"/> Discord | Webhook | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | | Test |
| <input type="checkbox"/> Email | Email | Enabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | SMTP server: "mail.example.com", SMTP helo: "example.com", email: "zabbix@example.com" | Test |
| <input type="checkbox"/> Email (HTML) | Email | Enabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | SMTP server: "mail.example.com", SMTP helo: "example.com", email: "zabbix@example.com" | Test |
| <input type="checkbox"/> Event-Driven Ansible | Webhook | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | | Test |
| <input type="checkbox"/> Express.ms | Webhook | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | | Test |
| <input type="checkbox"/> Github | Webhook | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | | Test |
| <input type="checkbox"/> GLPI | Webhook | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | | Test |
| <input type="checkbox"/> Gmail | Email | Disabled | 4 Report not supported items, Report not supported low level discovery rules, Report problems to Zabbix administrators, Report unknown triggers | SMTP server: "smtp.gmail.com", email: "zabbix@example.com" | Test |

Some media types come pre-defined in the default dataset. You just need to finetune their parameters to get them working.

Automated Gmail/Office365 media types

Gmail or Office365 users may benefit from easier media type configuration. The *Email provider* field in the mail media type configuration allows to select pre-configured options for Gmail and Office 365.

When selecting the Gmail/Office365 related options, it is only required to supply the sender email address/password to create a working media type.

New media type

☒

Add
Cancel

As soon as the email address/password is supplied, Zabbix will be able to automatically fill all required settings for Gmail/Office365 media types with the actual/recommended values, i.e., *SMTP server*, *SMTP server port*, *SMTP helo*, and *Connection security*. Because of this automation, these fields are not even shown, however, it is possible to see the SMTP server and email details in the media type list (see the *Details* column).

Note also that:

- The password is not required for the relay options.
- For Office365 relay, the domain name of the provided email address will be used to dynamically fill the SMTP server (i.e., replace "example.com" in example-com.mail.protection.outlook.com with the real value).

To test if a configured media type works, click on the *Test* link in the last column (see media type testing for [Email](#), [Webhook](#), or [Script](#) for more details).

To create a new media type, click on the *Create media type* button. A media type configuration form is opened.

Common parameters

Some parameters are common for all media types.

New media type
?
X

Media type
Message templates 5

In the **Media type** tab the common general attributes are:

| Parameter | Description |
|--------------------|---|
| <i>Name</i> | Name of the media type. |
| <i>Type</i> | Select the type of media. |
| <i>Description</i> | Enter a description. |
| <i>Enabled</i> | Mark the checkbox to enable the media type. |

See the individual pages of media types for media-specific parameters.

The **Message templates** tab allows to set default notification messages for all or some of the following event types:

- Problem
- Problem recovery
- Problem update
- Service
- Service recovery
- Service update
- Discovery
- Autoregistration
- Internal problem
- Internal problem recovery

Media type
?
X

Media type
Message templates 6
Options

Message templates

| Message type | Template | Actions |
|---------------------|---|---|
| Problem | Problem started at {EVENT.TIME} on {EVENT.DATE} Pro... | Edit Remove |
| Problem recovery | Problem has been resolved at {EVENT.RECOVERY.TIM... | Edit Remove |
| Problem update | {USER.FULLNAME} {EVENT.UPDATE.ACTION} problem... | Edit Remove |
| Service | Service problem started at {EVENT.TIME} on {EVENT.DA... | Edit Remove |
| Service recovery | Service "{SERVICE.NAME}" has been resolved at {EVEN... | Edit Remove |
| Autoregistration | Host name: {HOST.HOST} Host IP: {HOST.IP} Agent port... | Edit Remove |
| Add | | |

To customize message templates:

1. In the *Message templates* tab click on [Add](#): a *Message template* popup window will open.
2. Select required *Message type* and edit *Subject* and *Message* texts.
3. Click on *Add* to save the message template.

Message template parameters:

| Parameter | Description |
|---------------------|--|
| <i>Message type</i> | Type of an event for which the default message should be used. Only one default message can be defined for each event type. |
| <i>Subject</i> | Subject of the default message. The subject may contain macros. It is limited to 255 characters. Subject is not available for SMS media type. |
| <i>Message</i> | The default message. It is limited to certain amount of characters depending on the database type (see Sending messages for more information). The message may contain supported macros . In problem and problem update messages, expression macros are supported (for example, {?avg(/host/key, 1h)}). |

To make changes to an existing message template: in the *Actions* column click on [Edit](#) to edit the template or click on [Remove](#) to delete the message template.

It is possible to define a custom message template for a specific action (see [action operations](#) for details). Custom messages defined in the action configuration will override default media type message template.

Warning:

Defining message templates is mandatory for all media types, including webhooks or custom alert scripts that do not use default messages for notifications. For example, an action "Send message to Pushover webhook" will fail to send problem notifications, if the Problem message for the Pushover webhook is not defined.

The **Options** tab contains alert processing settings. The same set of options is configurable for each media type.

All media types are processed in parallel. While the maximum number of concurrent sessions is configurable per media type, the total number of alerter processes on the server can only be limited by the `StartAlerters` [parameter](#). Alerts generated by one trigger are processed sequentially. So multiple notifications may be processed simultaneously only if they are generated by multiple triggers.

New media type

* Attempt interval
10s

Add
Cancel

| Parameter | Description |
|----------------------------|---|
| <i>Concurrent sessions</i> | Select the number of parallel alerter sessions for the media type: One - one session Unlimited - unlimited number of sessions Custom - select a custom number of sessions Unlimited/high values mean more parallel sessions and increased capacity for sending notifications. Unlimited/high values should be used in large environments where lots of notifications may need to be sent simultaneously. If more notifications need to be sent than there are concurrent sessions, the remaining notifications will be queued; they will not be lost. |
| <i>Attempts</i> | Number of attempts for trying to send a notification. Up to 100 attempts can be specified; the default value is '3'. If '1' is specified, Zabbix will send the notification only once and will not retry if the sending fails. |
| <i>Attempt interval</i> | Frequency of trying to resend a notification in case the sending failed, in seconds (0-3600). If '0' is specified, Zabbix will retry immediately. Time suffixes are supported, e.g., 5s, 3m, 1h. |

User media

To receive notifications of a media type, a medium (email address/phone number/webhook user ID, etc.) for this media type must be defined in the user profile. For example, an action sending messages to user "Admin" using webhook "X" will always fail to send anything if the webhook "X" medium is not defined in the user profile.

To define user media:

1. Go to your user profile, or go to *Users* → *Users* and open the user properties form.
2. In the Media tab, click on [Add](#)

User media attributes:

| Parameter | Description |
|-----------------|---|
| Type | The drop-down list contains the names of enabled media types. Note that when editing a medium of a disabled media type, the type will be displayed in red. |
| Send to | Provide required contact information where to send messages. For an email media type it is possible to add several addresses by clicking on Add below the address field. In this case, the notification will be sent to all email addresses provided. It is also possible to specify recipient name in the <i>Send to</i> field of the email recipient in a format 'Recipient name <address1@company.com>'. Note that if a recipient name is provided, an email address should be wrapped in angle brackets (<>). UTF-8 characters in the name are supported, quoted pairs and comments are not. For example: <i>John Abercroft <manager@nycdatcenter.com></i> and <i>manager@nycdatcenter.com</i> are both valid formats. Incorrect examples: <i>John Doe zabbix@company.com</i> , <i>%%"Zabbix @ <H(comment)Q >" zabbix@company.com</i> %%. When active |
| When active | You can limit the time when messages are sent, for example, set the working days only (1-5,09:00-18:00). Note that this limit is based on the user time zone . If the user time zone is changed and is different from the system time zone this limit may need to be adjusted accordingly so as not to miss important messages. See the Time period specification page for description of the format. |
| Use if severity | User macros are supported. Mark the checkboxes of trigger severities that you want to receive notifications for. Note that the default severity ('Not classified') must be checked if you want to receive notifications for non-trigger events . After saving, the selected trigger severities will be displayed in the corresponding severity colors, while unselected ones will be grayed out. |
| Status | Status of the user media. Enabled - is in use. Disabled - is not being used. |

1 Email

Overview

To configure email as the delivery channel for messages, you need to configure email as the media type and assign specific addresses to users.

Note:
Multiple notifications for single event will be grouped together on the same email thread.

Configuration

To configure email as the media type:

- 1. Go to *Alerts* → *Media types*.
- 2. Click on *Create media type* (or click on *Email* in the list of pre-defined media types).

The **Media type** tab contains general media type attributes:

New media type

All mandatory input fields are marked with a red asterisk.

The following parameters are specific for the email media type:

| Parameter | Description |
|----------------|---|
| Email provider | Select the email provider: <i>Generic SMTP</i> , <i>Gmail</i> , <i>Gmail relay</i> , <i>Office365</i> , or <i>Office365 relay</i> . If you select the Gmail/Office365-related options, you will only need to supply the sender email address and password; such options as <i>SMTP server</i> , <i>SMTP server port</i> , <i>SMTP helo</i> , and <i>Connection security</i> will be automatically filled by Zabbix. See also: Automated Gmail/Office365 media types . |
| SMTP server | Set an SMTP server to handle outgoing messages. This field is available if <i>Generic SMTP</i> is selected as the email provider. |

| Parameter | Description |
|----------------------------|--|
| <i>SMTP server port</i> | Set the SMTP server port to handle outgoing messages. This field is available if <i>Generic SMTP</i> is selected as the email provider. |
| <i>Email</i> | The address entered here will be used as the From address for the messages sent. Adding a sender display name (like "Zabbix_info" in <i>Zabbix_info <zabbix@company.com></i> in the screenshot above) with the actual email address is supported. There are some restrictions on display names in Zabbix emails in comparison to what is allowed by RFC 5322, as illustrated by examples: Valid examples: <i>zabbix@company.com</i> (only email address, no need to use angle brackets) <i>Zabbix_info <zabbix@company.com></i> (display name and email address in angle brackets) <i>ΣΩ-monitoring <zabbix@company.com></i> (UTF-8 characters in display name) Invalid examples: <i>Zabbix HQ zabbix@company.com</i> (display name present but no angle brackets around email address) <i>"Zabbix\@ <H(comment)Q >" <zabbix@company.com></i> (although valid by RFC 5322, quoted pairs and comments are not supported in Zabbix emails) |
| <i>SMTP helo</i> | Set a correct SMTP helo value, normally a domain name. If empty, the domain name of the email will be sent (i.e., what comes after @ in the <i>Email</i> field). If it is impossible to fetch the domain name, a debug-level warning will be logged and the server hostname will be sent as the domain for HELO command. This field is available if <i>Generic SMTP</i> is selected as the email provider. |
| <i>Connection security</i> | Select the level of connection security: None - do not use the CURLOPT_USE_SSL option STARTTLS - use the CURLOPT_USE_SSL option with CURLUSESSL_ALL value SSL/TLS - use of CURLOPT_USE_SSL is optional |
| <i>SSL verify peer</i> | Mark the checkbox to verify the SSL certificate of the SMTP server. The value of "SSLCALocation" server configuration directive should be put into CURLOPT_CAPATH for certificate validation. This sets cURL option CURLOPT_SSL_VERIFYPEER . |
| <i>SSL verify host</i> | Mark the checkbox to verify that the <i>Common Name</i> field or the <i>Subject Alternate Name</i> field of the SMTP server certificate matches. This sets cURL option CURLOPT_SSL_VERIFYHOST . |
| <i>Authentication</i> | Select the level of authentication: None - no cURL options are set Username and password - implies "AUTH=*" leaving the choice of authentication mechanism to cURL |
| <i>Username</i> | User name to use in authentication. This sets the value of CURLOPT_USERNAME . User macros supported. |
| <i>Password</i> | Password to use in authentication. This sets the value of CURLOPT_PASSWORD . User macros supported. |
| <i>Message format</i> | Select message format: HTML - send as HTML Plain text - send as plain text |

Attention:

To enable SMTP authentication options, Zabbix server must be both compiled with the `--with-libcurl` **compilation** option (with cURL 7.20.0 or higher) and use the `libcurl-full` packages during runtime.

See also [common media type parameters](#) for details on how to configure default messages and alert processing options.

Media type testing

To test whether a configured email media type works correctly:

1. Locate the relevant email in the **list** of media types.
2. Click on *Test* in the last column of the list (a testing window will open).
3. Enter a *Send to* recipient address, message body and, optionally, subject.
4. Click on *Test* to send a test message.

Test success or failure message will be displayed in the same window:

Test media type "Email" ✕

✓

Media type test successful.

✕

* Send to

address@domain.com

Subject

Test subject

* Message

This is the test message from Zabbix

Test

Cancel

User media

Once the email media type is configured, go to the *Users* → *Users* section and edit user profile to assign email media to the user. Steps for setting up user media, being common for all media types, are described on the [Media types](#) page.

2 SMS

Overview

Zabbix supports the sending of SMS messages using a serial GSM modem connected to Zabbix server's serial port.

Make sure that:

- The speed of the serial device (normally `/dev/ttyS0` under Linux) matches that of the GSM modem. Zabbix does not set the speed of the serial link. It uses default settings.
- The 'zabbix' user has read/write access to the serial device. Run the command `ls -l /dev/ttyS0` to see current permissions of the serial device.
- The GSM modem has PIN entered and it preserves it after power reset. Alternatively you may disable PIN on the SIM card. PIN can be entered by issuing command `AT+CPIN="NNNN"` (NNNN is your PIN number, the quotes must be present) in a terminal software, such as Unix minicom or Windows HyperTerminal.

Zabbix has been tested with these GSM modems:

- Siemens MC35
- Teltonika ModemCOM/G10

To configure SMS as the delivery channel for messages, you also need to configure SMS as the media type and enter the respective phone numbers for the users.

Configuration

To configure SMS as the media type:

- Go to *Alerts* → *Media types*
- Click on *Create media type* (or click on *SMS* in the list of pre-defined media types).

The following parameters are specific for the SMS media type:

| Parameter | Description |
|------------------|---|
| <i>GSM modem</i> | Set the serial device name of the GSM modem. The path entered here will be validated against the SMSDevices server parameter (if specified). |

See [common media type parameters](#) for details on how to configure default messages and alert processing options. Note that parallel processing of sending SMS notifications is not possible.

User media

Once the SMS media type is configured, go to the *Users → Users* section and edit user profile to assign SMS media to the user. Steps for setting up user media, being common for all media types, are described on the [Media types](#) page.

3 Custom alert scripts

Overview

If you are not satisfied with the existing media types for sending alerts, there is an alternative way to do that. You can create a script that will handle the notification your way.

Custom alert scripts are executed on Zabbix server. These scripts must be located in the directory specified in the server configuration file `AlertScriptsPath` parameter.

Here is an example of a custom alert script:

```
#####!/bin/bash

to=$1
subject=$2
body=$3
host=$4
value=$5

cat <<EOF | mail -s "$subject" "$to"
$body

Host: $host
Value: $value
EOF
```

Attention:

Zabbix checks for the exit code of the executed commands and scripts. Any exit code, which is different from **0**, is considered as a **command execution** error. In such cases, Zabbix will try to repeat failed execution.

Environment variables are not preserved or created for the script, so they should be handled explicitly.

Configuration

To configure custom alert scripts as a media type:

1. Go to *Alerts → Media types*.
2. Click on *Create media type*.

The **Media type** tab contains general media type attributes:

Media type
Message templates
Options

* Name
Notification script

Type
Script

* Script name
notification.sh

Script parameters
?

| Value | Action |
|------------------|--------|
| {ALERT.SENDTO} | Remove |
| {ALERT.SUBJECT} | Remove |
| {ALERT.MESSAGE} | Remove |
| {HOST.HOST} | Remove |
| {ITEM.LASTVALUE} | Remove |
| Add | |

Description

Enabled
☒

Add
Cancel

All mandatory input fields are marked with a red asterisk.

The following parameters are specific for the script media type:

| Parameter | Description |
|--------------------------|---|
| <i>Script name</i> | Enter the name of the script file (e.g., notification.sh) that is located in the directory specified in the AlertScriptsPath server configuration parameter. |
| <i>Script parameters</i> | Add optional script parameters that will be passed to the script as command-line arguments in the order in which they are defined. Script parameters support {ALERT.SENDTO}, {ALERT.SUBJECT}, {ALERT.MESSAGE} macros, and all macros that are supported in notifications, as well as user macros . |

See **common media type parameters** for details on how to configure default messages and alert processing options.

Warning:

Even if an alert script does not use default messages, the message templates for operation types used by this media type must still be defined. Otherwise, a notification will not be sent.

Attention:

If more than one script media type is configured, these scripts may be processed in parallel by the alerter processes. The total number of alerter processes is limited by the server configuration file **StartAlerters** parameter.

Media type testing

To test a configured script media type:

1. Locate the relevant script in the **list** of media types.
2. Click on *Test* in the last column of the list; a testing form will open in a pop-up window. The testing form will contain the same number of parameters that are configured for the script media type.

3. Edit the script parameter values if needed. Editing only affects the test procedure; the actual values will not be changed.
4. Click on *Test*.

Cancel

Note:

When testing a configured script media type, {ALERT.SENDTO}, {ALERT.SUBJECT}, {ALERT.MESSAGE} and user macros will resolve to their values, but macros that are related to events (e.g., {HOST.HOST}, {ITEM.LASTVALUE}, etc.) will not resolve, as during testing there is no related event to get the details from. Note that macros within {ALERT.SUBJECT} and {ALERT.MESSAGE} macros will also not resolve. For example, if the value of {ALERT.SUBJECT} is composed of "Problem: {EVENT.NAME}" then the {EVENT.NAME} macro will not be resolved.

User media

Once the media type is configured, go to the *Users* → *Users* section and edit a user profile by assigning this media type to the user. Steps for setting up user media, being common for all media types, are described on the [Media types](#) page.

Note that when defining the user media, the *Send to* field cannot be empty. If this field is not used in the alert script, enter any combination of supported characters to bypass validation requirements.

4 Webhook

Overview

The webhook media type is useful for making HTTP calls using custom JavaScript code for straightforward integration with external software such as helpdesk systems, chats, or messengers. You may choose to import an integration provided by Zabbix or create a custom integration from scratch.

Integrations

The following integrations are available allowing to use predefined webhook media types for pushing Zabbix notifications to:

- [brevis.one](#)
- [Discord](#)
- [Event-Driven Ansible](#)
- [Express.ms messenger](#)
- [GitHub](#)
- [GLPi](#)
- [iLert](#)
- [iTop](#)
- [Jira](#)
- [Jira Service Management](#)
- [ManageEngine ServiceDesk](#)
- [Mantis Bug Tracker](#)
- [Mattermost](#)
- [MS Teams](#)
- [MS Teams Workflows](#)
- [LINE](#)
- [Opsgenie](#)
- [OTRS CE](#)
- [PagerDuty](#)
- [Pushover](#)

- [Redmine](#)
- [Rocket.Chat](#)
- [ServiceNow](#)
- [SIGNL4](#)
- [Slack](#)
- [SolarWinds](#)
- [SysAid](#)
- [Telegram](#)
- [TOPdesk](#)
- [VictorOps](#)
- [Zammad](#)
- [Zendesk](#)

Note:

In addition to the services listed here, Zabbix can be integrated with **Spiceworks** (no webhook is required). To convert Zabbix notifications into Spiceworks tickets, create an **email media type** and enter Spiceworks helpdesk email address (e.g. `help@zabbix.on.spiceworks.com`) in the profile settings of a designated Zabbix user.

Configuration

To start using a webhook integration:

1. Locate required .xml file in the `templates/media` directory of the downloaded Zabbix version or download it from [Zabbix git repository](#).
2. **Import** the file into your Zabbix installation. The webhook will appear in the list of media types.
3. Configure the webhook according to instructions in the *Readme.md* file (you may click on a webhook's name above to quickly access *Readme.md*).

To create a custom webhook from scratch:

1. Go to *Alerts* → *Media types*.
2. Click on *Create media type*.

The **Media type** tab contains various attributes specific for this media type:

All mandatory input fields are marked with a red asterisk.

The following parameters are specific for the webhook media type:

| Parameter | Description |
|---------------------------------|---|
| <i>Parameters</i> | <p>Specify the webhook variables as the attribute and value pairs.</p> <p>For preconfigured webhooks, a list of parameters varies, depending on the service. Check the webhook's <i>Readme.md</i> file for parameter description.</p> <p>For new webhooks, several common variables are included by default (URL:<empty>, HTTPProxy:<empty>, To:{ALERT.SENDTO}, Subject:{ALERT.SUBJECT}, Message:{ALERT.MESSAGE}), feel free to keep or remove them.</p> <p>Webhook parameters support user macros, all macros that are supported in problem notifications and, additionally, {ALERT.SENDTO}, {ALERT.SUBJECT}, and {ALERT.MESSAGE} macros.</p> <p>If you specify an HTTP proxy, the field supports the same functionality as in the item configuration HTTP proxy field. The proxy string may be prefixed with [scheme] :// to specify which kind of proxy is used (e.g., https, socks4, socks5; see documentation).</p> |
| <i>Script</i> | <p>Enter JavaScript code in the modal editor that opens when clicking in the parameter field or on the pencil icon next to it. This code will perform the webhook operation.</p> <p>The script is a function code that accepts parameter - value pairs. The values should be converted into JSON objects using JSON.parse() method, for example: <code>var params = JSON.parse(value);</code>.</p> <p>The code has access to all parameters, it may perform HTTP GET, POST, PUT and DELETE requests and has control over HTTP headers and request body.</p> <p>The script must contain a return operator, otherwise it will not be valid. It may return OK status along with an optional list of tags and tag values (see <i>Process tags</i> option) or an error string.</p> <p>Note that the script is executed only after an alert is created. If the script is configured to return and process tags, these tags will not get resolved in {EVENT.TAGS} and {EVENT.RECOVERY.TAGS} macros in the initial problem message and recovery messages because the script has not had the time to run yet.</p> <p><i>Note:</i> Using local variables (e.g. <code>var local = 1</code>) instead of a global one (e.g. <code>global = 1</code>) is recommended to ensure each script operates on its own data and to avoid collisions between simultaneous calls (see known issues).</p> <p>See also: Webhook development guidelines, Webhook script examples, Additional JavaScript objects.</p> |
| <i>Timeout</i> | <p>JavaScript execution timeout (1-60s, default 30s).</p> <p>Time suffixes are supported, e.g., 30s, 1m.</p> |
| <i>Process tags</i> | <p>Mark the checkbox to process returned JSON property values as tags. These tags are added to any existing problem tags.</p> <p>Note that when using webhook tags, the webhook must return a JSON object containing at least an empty tags object: <code>var result = {tags: {}};</code></p> <p>Examples of tags that can be returned: <i>jira-id:prod-1234, responsible:John Smith, processed:<no value></i></p> |
| <i>Include event menu entry</i> | <p>Mark the checkbox to include an entry in the event menu linking to a created external ticket. An entry will be included for each webhook that is enabled and has this checkbox marked. Note that if the <i>Menu entry name</i> and <i>Menu entry URL</i> parameters contain any {EVENT.TAGS.<tag name>} macros, an entry will be included only if these macros can be resolved (that is, the event has these tags defined).</p> <p>If marked, the webhook should not be used for sending notifications to different users (consider creating a dedicated user instead) and should not be used in multiple alert actions for a single problem event.</p> |
| <i>Menu entry name</i> | <p>Specify the menu entry name.</p> <p>{EVENT.TAGS.<tag name>} macro is supported.</p> |
| <i>Menu entry URL</i> | <p>This field is only mandatory if <i>Include event menu entry</i> is marked.</p> <p>Specify the underlying URL of the menu entry.</p> <p>{EVENT.TAGS.<tag name>} macro is supported.</p> <p>This field is only mandatory if <i>Include event menu entry</i> is marked.</p> |

See [common media type parameters](#) for details on how to configure default messages and alert processing options.

Warning:

Even if a webhook doesn't use default messages, message templates for operation types used by this webhook must still be defined.

Media type testing

To test a configured webhook media type:

1. Locate the relevant webhook in the **list** of media types.
2. Click on *Test* in the last column of the list (a testing window will open).
3. Edit the webhook parameter values as needed. Replace macros with example values; otherwise, macros will not resolve, and the test will fail.
4. Click on *Test*.

Replacing or deleting values in the testing window affects the test procedure only, the actual webhook attribute values will remain unchanged.

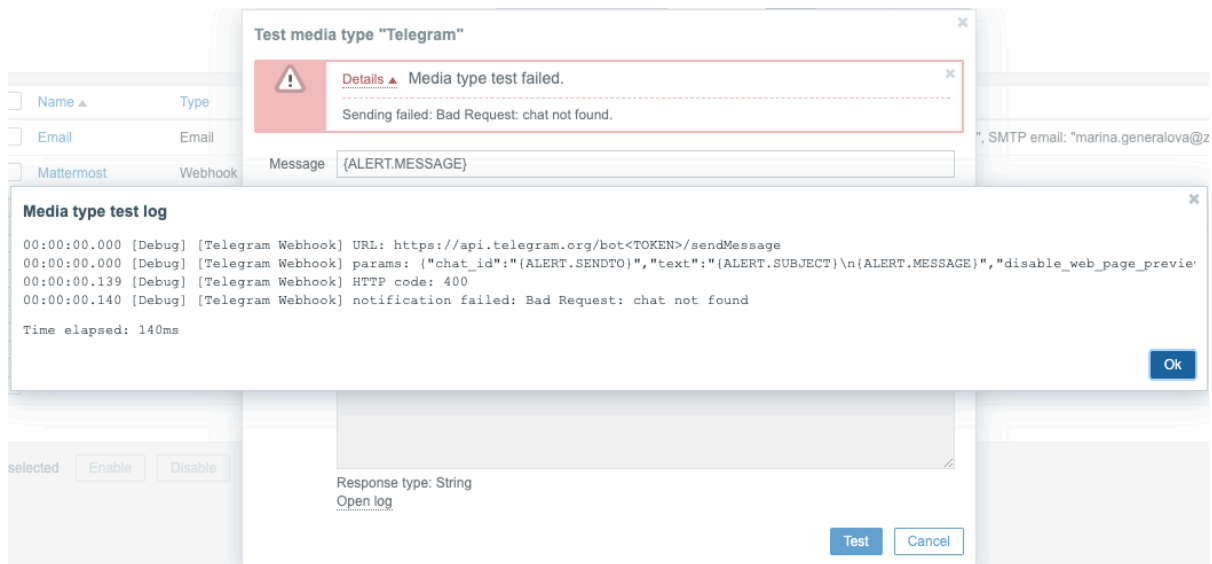

Test media type "Telegram"

 Media type test successful.

| | |
|------------------------|---|
| alert_message | Test alert message |
| alert_subject | Test |
| api_chat_id | 556981083 |
| api_parse_mode | markdown |
| api_token | 7903122191:AAHP68_tG3KTP3vp9eh0NwkWawYJrnf6Ogo |
| event_nseverity | 2 |
| event_severity | Warning |
| event_source | 0 |
| event_tags | [] |
| event_update_nseverity | |
| event_update_severity | |
| event_update_status | 0 |
| event_value | 0 |
| Response | <pre>{ "tags": { "__telegram_msg_id_556981083": 2 } }</pre> |

Test **Cancel**

To view media type test log entries without leaving the test window, click on *Open log* (a new pop-up window will open).

If the webhook test is successful:

- "Media type test successful." message is displayed.
- Server response appears in the gray *Response* field.
- Response type (JSON or String) is specified below the *Response* field.

If the webhook test fails:

- "Media type test failed." message is displayed, followed by additional failure details.

User media

Once the media type is configured, go to the *Users* → *Users* section and assign the webhook media to an existing user or create a new user to represent the webhook. Steps for setting up user media for an existing user, being common for all media types, are described on the [Media types](#) page.

If a webhook uses tags to store ticket\message ID, avoid assigning the same webhook as a media to different users as doing so may cause webhook errors (applies to the majority of webhooks that utilize *Include event menu entry* option). In this case, the best practice is to create a dedicated user to represent the webhook:

1. After configuring the webhook media type, go to the *Users* → *Users* section and create a dedicated Zabbix user to represent the webhook - for example, with a username *Slack* for the Slack webhook. All settings, except media, can be left at their defaults as this user will not be logging into Zabbix.
2. In the user profile, go to a tab *Media* and **add a webhook** with the required contact information. If the webhook does not use a *Send to* field, enter any combination of supported characters to bypass validation requirements.
3. Grant this user at least read **permissions** to all hosts for which it should send the alerts.

When configuring alert action, add this user in the *Send to users* field in Operation details - this will tell Zabbix to use the webhook for notifications from this action.

Configuring alert actions

Actions determine which notifications should be sent via the webhook. Steps for **configuring actions** involving webhooks are the same as for all other media types with these exceptions:

- If a webhook uses **webhook tags** to store ticket\message ID and handle update\resolve operations, avoid using the same webhook in multiple alert actions for a single problem event. If {EVENT.TAGS.<tag name>} exists and gets updated in the webhook, its resulting value will be undefined. To avoid this, use a new tag name in the webhook for storing updated values. This applies to Jira, Jira Service Desk, Mattermost, Opsgenie, OTRS, Redmine, ServiceNow, Slack, Zammad, and Zendesk webhooks provided by Zabbix and to most webhooks utilizing the *Include event menu entry* option. Note, however, that a single webhook can be used in multiple operations or escalation steps of the same action, as well as in different actions that will not be triggered by the same problem event due to different **conditions**.
- When using a webhook in actions for **internal events**, ensure to mark the *Custom message* checkbox and define a custom message in the action operation configuration. Otherwise, a notification will not be sent.

1 Webhook script examples

Overview

Though Zabbix offers a large number of webhook integrations available out-of-the-box, you may want to create your own webhooks instead. This section provides examples of custom webhook scripts (used in the *Script* parameter). See [webhook](#) section for description of other webhook parameters.

Cancel

This script will create a JIRA issue and return some info on the created issue.

```
try {
  Zabbix.log(4, '[ Jira webhook ] Started with params: ' + value);

  var result = {
    'tags': {
      'endpoint': 'jira'
    }
  },
  params = JSON.parse(value),
  req = new HttpRequest(),
  fields = {},
  resp;

  if (params.HTTPProxy) {
    req.setProxy(params.HTTPProxy);
  }
}
```

```

}

req.addHeader('Content-Type: application/json');
req.addHeader('Authorization: Basic ' + params.authentication);

fields.summary = params.summary;
fields.description = params.description;
fields.project = {key: params.project_key};
fields.issuetype = {id: params.issue_id};

resp = req.post('https://jira.example.com/rest/api/2/issue/',
    JSON.stringify({"fields": fields})
);

if (req.getStatus() != 201) {
    throw 'Response code: ' + req.getStatus();
}

resp = JSON.parse(resp);
result.tags.issue_id = resp.id;
result.tags.issue_key = resp.key;

return JSON.stringify(result);
}
catch (error) {
    Zabbix.log(4, '[ Jira webhook ] Issue creation failed json : ' + JSON.stringify({"fields": fields}));
    Zabbix.log(3, '[ Jira webhook ] issue creation failed : ' + error);

    throw 'Failed with error: ' + error;
}

```

Slack webhook (custom)

This webhook will forward notifications from Zabbix to a Slack channel.

    if (req.getStatus() < 200 || req.getStatus() >= 300) {
        throw 'Request failed with status code ' + req.getStatus();
    }
    else {
        throw 'Request success, but response parsing failed.';
    }
}

if (req.getStatus() !== 200 || !response.ok || response.ok === 'false') {
    throw response.error;
}

return 'OK';
}
catch (error) {
    Zabbix.log(3, '[ Slack webhook ] Sending failed. Error: ' + error);

    throw 'Failed with error: ' + error;
}
}

```

2 Actions

Overview

If you want some operations taking place as a result of events (for example, notifications sent), you need to configure actions.

Actions can be defined in response to events of all supported types:

- Trigger actions - for events when trigger status changes from *OK* to *PROBLEM* and back
- Service actions - for events when service status changes from *OK* to *PROBLEM* and back
- Discovery actions - for events when network discovery takes place
- Autoregistration actions - for events when new active agents auto-register (or host metadata changes for registered ones)
- Internal actions - for events when items become unsupported or triggers go into an unknown state

The key differences of service actions are:

- User access to service actions depends on access rights to services granted by user's **role**
- Service actions support different set of **conditions**

Configuring an action

To configure an action, do the following:

- Go to *Alerts* → *Actions* and select the required action type from the submenu (you can switch to another type later, using the title dropdown)
- Click on *Create action*
- Name the action
- Choose **conditions** upon which operations are carried out
- Choose the **operations** to carry out

General action attributes:

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|----------------------------|--|
| <i>Name</i> | Unique action name. |
| <i>Type of calculation</i> | Select the evaluation option for action conditions (with more than one condition): And - all conditions must be met. Or - enough if one condition is met. And/Or - combination of the two: AND with different condition types and OR with the same condition type. Custom expression - a user-defined calculation formula for evaluating action conditions. |
| <i>Conditions</i> | List of action conditions. Click on <i>Add</i> to add a new condition . If no conditions are configured, the action will run for every event that corresponds to the action type being configured. |
| <i>Enabled</i> | Mark the checkbox to enable the action. Otherwise, it will be disabled. |

1 Conditions

Overview

It is possible to define that an action is executed only if the event matches a defined set of conditions. Conditions are set when configuring the **action**.

Condition matching is case-sensitive.

Trigger actions

The following conditions can be used in trigger-based actions:

| Condition type | Supported operators | Description |
|-------------------|--------------------------|---|
| <i>Host group</i> | equals does not equal | Specify host groups or host groups to exclude. equals - event belongs to this host group. does not equal - event does not belong to this host group. Specifying a parent host group implicitly selects all nested host groups. To specify the parent group only, all nested groups have to be additionally set with the does not equal operator. |

| Condition type | Supported operators | Description |
|------------------------------|---|---|
| <i>Template</i> | equals does not equal | Specify templates or templates to exclude. equals - event belongs to a trigger inherited from this template. does not equal - event does not belong to a trigger inherited from this template. |
| <i>Host</i> | equals does not equal | Specify hosts or hosts to exclude. equals - event belongs to this host. does not equal - event does not belong to this host. |
| <i>Tag name</i> | equals does not equal contains does not contain | Specify event tag or event tag to exclude. equals - event has this tag. does not equal - event does not have this tag. contains - event has a tag containing this string. does not contain - event does not have a tag containing this string. |
| <i>Tag value</i> | equals does not equal contains does not contain | Specify event tag and value combination or tag and value combination to exclude. equals - event has this tag and value. does not equal - event does not have this tag and value. contains - event has a tag and value containing these strings. does not contain - event does not have a tag and value containing these strings. |
| <i>Trigger</i> | equals does not equal | Specify triggers or triggers to exclude. equals - event is generated by this trigger. does not equal - event is generated by any other trigger, except this one. |
| <i>Event name</i> | contains does not contain | Specify a string in the name of the event generated by the trigger or a string to exclude. By default, the event name matches the trigger name unless a custom event name is specified in trigger configuration . contains - event name contains this string. does not contain - this string is excluded from the event name. Note: Entered value will be compared to event name with all macros expanded. |
| <i>Trigger severity</i> | equals does not equal is greater than or equals is less than or equals | Specify trigger severity. equals - equal to trigger severity. does not equal - not equal to trigger severity. is greater than or equals - more or equal to trigger severity. is less than or equals - less or equal to trigger severity. |
| <i>Time period</i> | in not in | Specify a time period or a time period to exclude. in - event time is within the time period. not in - event time is not within the time period. See the time period specification page for description of the format. User macros are supported. |
| <i>Problem is suppressed</i> | no yes | Specify if the problem is suppressed (not shown) because of host maintenance. no - problem is not suppressed. yes - problem is suppressed. |

Service actions

The following conditions can be used in service actions:

| Condition type | Supported operators | Description |
|----------------|--------------------------|---|
| <i>Service</i> | equals does not equal | Specify a service or a service to exclude. equals - event belongs to this service. does not equal - event does not belong to this service. Specifying a parent service implicitly selects all child services. To specify the parent service only, all nested services have to be additionally set with the does not equal operator. |

| Condition type | Supported operators | Description |
|--------------------------|--|--|
| <i>Service name</i> | contains does not contain | Specify a string in the service name or a string to exclude. contains - event is generated by a service, containing this string in the name. does not contain - this string cannot be found in the service name. |
| <i>Service tag name</i> | equals does not equal contains does not contain | Specify an event tag or an event tag to exclude. Service event tags can be defined in the service configuration section <i>Tags</i> . equals - event has this tag. does not equal - event does not have this tag. contains - event has a tag containing this string. does not contain - event does not have a tag containing this string. |
| <i>Service tag value</i> | equals does not equal contains does not contain | Specify an event tag and value combination or a tag and value combination to exclude. Service event tags can be defined in the service configuration section <i>Tags</i> . equals - event has this tag and value. does not equal - event does not have this tag and value. contains - event has a tag and value containing these strings. does not contain - event does not have a tag and value containing these strings. |

Attention:

Make sure to define **message templates** for Service actions in the *Alerts* → *Media types* menu. Otherwise, the notifications will not be sent.

Discovery actions

The following conditions can be used in discovery-based events:

| Condition type | Supported operators | Description |
|-------------------------|--------------------------|--|
| <i>Host IP</i> | equals does not equal | Specify an IP address range or a range to exclude for a discovered host. equals - host IP is in the range. does not equal - host IP is not in the range. It may have the following formats: Single IP: 192.168.1.33 Range of IP addresses: 192.168.1-10.1-254 IP mask: 192.168.4.0/24 List: 192.168.1.1-254, 192.168.2.1-100, 192.168.2.200, 192.168.4.0/24 Spaces in the list format are supported. |
| <i>Service type</i> | equals does not equal | Specify a service type of a discovered service or a service type to exclude. equals - matches the discovered service. does not equal - does not match the discovered service. Available service types: SSH, LDAP, SMTP, FTP, HTTP, HTTPS, POP, NNTP, IMAP, TCP, Zabbix agent, SNMPv1 agent, SNMPv2 agent, SNMPv3 agent, ICMP ping, telnet. |
| <i>Service port</i> | equals does not equal | Specify a TCP port range of a discovered service or a range to exclude. equals - service port is in the range. does not equal - service port is not in the range. |
| <i>Discovery rule</i> | equals does not equal | Specify a discovery rule or a discovery rule to exclude. equals - using this discovery rule. does not equal - using any other discovery rule, except this one. |
| <i>Discovery check</i> | equals does not equal | Specify a discovery check or a discovery check to exclude. equals - using this discovery check. does not equal - using any other discovery check, except this one. |
| <i>Discovery object</i> | equals | Specify the discovered object. equals - equal to discovered object (a device or a service). |

| Condition type | Supported operators | Description |
|-------------------------|---|---|
| <i>Discovery status</i> | equals | Up - matches 'Host Up' and 'Service Up' events. Down - matches 'Host Down' and 'Service Down' events. Discovered - matches 'Host Discovered' and 'Service Discovered' events. Lost - matches 'Host Lost' and 'Service Lost' events. |
| <i>Uptime/Downtime</i> | is greater than or equals is less than or equals | Uptime for 'Host Up' and 'Service Up' events. Downtime for 'Host Down' and 'Service Down' events. is greater than or equals - is more or equal to. Parameter is given in seconds. is less than or equals - is less or equal to. Parameter is given in seconds. |
| <i>Received value</i> | equals does not equal is greater than or equals is less than or equals contains does not contain | Specify the value received from an agent (Zabbix, SNMP) check in a discovery rule. String comparison. If several Zabbix agent or SNMP checks are configured for a rule, received values for each of them are checked (each check generates a new event which is matched against all conditions). equals - equal to the value. does not equal - not equal to the value. is greater than or equals - more or equal to the value. is less than or equals - less or equal to the value. contains - contains the substring. Parameter is given as a string. does not contain - does not contain the substring. Parameter is given as a string. |
| <i>Proxy</i> | equals does not equal | Specify a proxy or a proxy to exclude. equals - using this proxy. does not equal - using any other proxy except this one. |

Note:

Service checks in a discovery rule, which result in discovery events, do not take place simultaneously. Therefore, if **multiple** values are configured for *Service type*, *Service port* or *Received value* conditions in the action, they will be compared to one discovery event at a time, but **not** to several events simultaneously. As a result, actions with multiple values for the same check types may not be executed correctly.

Autoregistration actions

The following conditions can be used in actions based on active agent autoregistration:

| Condition type | Supported operators | Description |
|----------------------|---|--|
| <i>Host metadata</i> | contains does not contain matches does not match | Specify host metadata or host metadata to exclude. contains - host metadata contains the string. does not contain - host metadata does not contain the string. Host metadata can be specified in an agent configuration file . matches - host metadata matches regular expression. does not match - host metadata does not match regular expression. |
| <i>Host name</i> | contains does not contain matches does not match | Specify a host name or a host name to exclude. contains - host name contains the string. does not contain - host name does not contain the string. matches - host name matches regular expression. does not match - host name does not match regular expression. |
| <i>Proxy</i> | equals does not equal | Specify a proxy or a proxy to exclude. equals - using this proxy. does not equal - using any other proxy except this one. |

Internal event actions

The following conditions can be set for actions based on internal events:

| Condition type | Supported operators | Description |
|-------------------|--|--|
| <i>Event type</i> | equals | Item in "not supported" state - matches events where an item goes from a 'normal' to 'not supported' state. Low-level discovery rule in "not supported" state - matches events where a low-level discovery rule goes from a 'normal' to 'not supported' state. Trigger in "unknown" state - matches events where a trigger goes from a 'normal' to 'unknown' state. |
| <i>Host group</i> | equals does not equal | Specify host groups or host groups to exclude. equals - event belongs to this host group. does not equal - event does not belong to this host group. |
| <i>Tag name</i> | equals does not equal contains does not contain | Specify event tag or event tag to exclude. equals - event has this tag. does not equal - event does not have this tag. contains - event has a tag containing this string. does not contain - event does not have a tag containing this string. |
| <i>Tag value</i> | equals does not equal contains does not contain | Specify event tag and value combination or tag and value combination to exclude. equals - event has this tag and value. does not equal - event does not have this tag and value. contains - event has a tag and value containing these strings. does not contain - event does not have a tag and value containing these strings. |
| <i>Template</i> | equals does not equal | Specify templates or templates to exclude. equals - event belongs to an item/trigger/low-level discovery rule inherited from this template. does not equal - event does not belong to an item/trigger/low-level discovery rule inherited from this template. |
| <i>Host</i> | equals does not equal | Specify hosts or hosts to exclude. equals - event belongs to this host. does not equal - event does not belong to this host. |

Type of calculation

The following options of calculating conditions are available:

- **And** - all conditions must be met

Note that using "And" calculation is disallowed between several triggers when they are selected as a Trigger= condition. Actions can only be executed based on the event of one trigger.

- **Or** - enough if one condition is met
- **And/Or** - combination of the two: AND with different condition types and OR with the same condition type, for example:

Host group equals Oracle servers

Host group equals MySQL servers

Event name contains 'Database is down'

Event name contains 'Database is unavailable'

is evaluated as

(Host group equals Oracle servers or Host group equals MySQL servers) and (Event name contains 'Database is down' or Event name contains 'Database is unavailable')

- **Custom expression** - a user-defined calculation formula for evaluating action conditions. It must include all conditions (represented as uppercase letters A, B, C, ...) and may include spaces, tabs, brackets (), **and** (case sensitive), **or** (case sensitive), **not** (case sensitive).

While the previous example with And/Or would be represented as (A or B) and (C or D), in a custom expression you may as well have multiple other ways of calculation:

(A and B) and (C or D)

(A and B) or (C and D)

((A or B) and C) or D

(not (A or B) and C) or not D

etc.

Deleting objects used in actions

When attempting to delete objects that are used in an action condition/operation, the user will receive a corresponding error message.

Actions are not disabled if action conditions or operations:

- have deleted objects;
- have objects that are no longer discovered by low-level discovery and have been removed (after the *Delete lost resources* period).

Action conditions/operations are not removed if they have missing objects. Instead, deleted objects are displayed as *Deleted host group*, *Deleted host*, *Deleted trigger*, etc. A warning icon with message "This action has conditions or operations referencing deleted object(s)." is displayed in the "Info" column of the action list.

Note that **before Zabbix 7.2.4**, if a certain object (host, template, trigger, etc.) used in an action condition/operation is deleted, the condition/operation is removed and the action is disabled.

2 Operations

Overview

You can define the following operations for all events:

- Send a message
- Execute a remote command

Attention:

Zabbix server does not create alerts if access to the host is explicitly "denied" for the user defined as action operation recipient or if the user has no rights defined to the host at all.

For discovery and autoregistration events, additional operations are available:

- **Add host**
- Remove host
- Enable host
- Disable host
- Add to host group
- Remove from host group
- Add host tags
- Remove host tags
- Link template
- Unlink template
- Set host inventory mode

Configuring an operation

To configure an operation, go to the *Operations* tab in **action** configuration.

General operation attributes:

| Parameter | Description |
|---|---|
| <i>Default operation step duration</i> | <p>Duration of one operation step by default (60 seconds to 1 week). For example, an hour-long step duration means that if an operation is carried out, an hour will pass before the next step.</p> <p>Time suffixes are supported, e.g. 60s, 1m, 2h, 1d.</p> <p>User macros are supported.</p> |
| <i>Operations</i> | <p>Action operations (if any) are displayed, with these details:</p> <p>Steps - escalation step(s) to which the operation is assigned.</p> <p>Details - type of operation and its recipient/target.</p> <p>The operation list also displays the media type (email, SMS or script) used as well as the name and surname (in parentheses after the username) of a notification recipient.</p> <p>Start in - how long after an event the operation is performed.</p> <p>Duration (sec) - step duration is displayed. <i>Default</i> is displayed if the step uses default duration, and a time is displayed if custom duration is used.</p> <p>Actions - links for editing and removing an operation are displayed.</p> |
| <i>Recovery operations</i> | <p>Action operations (if any) are displayed, with these details:</p> <p>Details - type of operation and its recipient/target.</p> <p>The operation list also displays the media type (email, SMS or script) used as well as the name and surname (in parentheses after the username) of a notification recipient.</p> <p>Actions - links for editing and removing an operation are displayed.</p> |
| <i>Update operations</i> | <p>Action operations (if any) are displayed, with these details:</p> <p>Details - type of operation and its recipient/target.</p> <p>The operation list also displays the media type (email, SMS or script) used as well as the name and surname (in parentheses after the username) of a notification recipient.</p> <p>Actions - links for editing and removing an operation are displayed.</p> |
| <i>Pause operations for symptom problems</i> | <p>Mark this checkbox to pause operations (after the first operation) for symptom problems. Note that this setting affects only problem escalations; recovery and update operations will not be affected.</p> <p>This option is available for <i>Trigger actions</i> only.</p> |
| <i>Pause operations for suppressed problems</i> | <p>Mark this checkbox to delay the start of operations for the duration of a maintenance period. When operations are started, after the maintenance, all operations are performed including those for the events during the maintenance.</p> <p>Note that this setting affects only problem escalations; recovery and update operations will not be affected.</p> <p>If you unmark this checkbox, operations will be executed without delay even during a maintenance period.</p> <p>This option is not available for <i>Service actions</i>.</p> |

| Parameter | Description |
|--|--|
| <i>Notify about canceled escalations</i> | Unmark this checkbox to disable notifications about canceled escalations (when host, item, trigger or action is disabled). |

All mandatory input fields are marked with a red asterisk.

To configure details of a new operation, click on [Add](#) in the *Operations* block. To edit an existing operation, click on [Edit](#) next to the operation. A pop-up window will open where you can edit the operation step details.

Conditions

| Label | Name | Action |
|-------|---------------------------|--------|
| A | Event is not acknowledged | Remove |

Add

Add

Cancel

| Parameter | Description |
|----------------------|---|
| <i>Operation</i> | <p>Select the operation:</p> <p>Send message - send message to user.</p> <p><remote command name> - execute a remote command. Commands are available for execution if previously defined in global scripts with <i>Action operation</i> selected as its scope.</p> <p>More operations are available for discovery and autoregistration based events (see above).</p> |
| <i>Steps</i> | <p>Select the step(s) to assign the operation to in an escalation schedule:</p> <p>From - execute starting with this step.</p> <p>To - execute until this step (0=infinity, execution will not be limited).</p> |
| <i>Step duration</i> | <p>Custom duration for these steps (0=use default step duration).</p> <p>Time suffixes are supported, e.g. 60s, 1m, 2h, 1d.</p> <p>User macros are supported.</p> |
| <i>Escalation</i> | <p>Several operations can be assigned to the same step. If these operations have different step duration defined, the shortest one is taken into account and applied to the step.</p> |

| Parameter | Description |
|--|--|
| Operation type: send mes- sage | |
| Send to user groups | Select user groups to send the message to. The user group must have at least "read" permissions to the host in order to be notified. |
| Send to users | Select users to send the message to. The user must have at least "read" permissions to the host in order to be notified. |
| Send to media type | Send message to all available (configured and enabled) media types or a specific one only. |
| Custom message | If selected, the custom message can be configured. For notifications about internal events via webhooks , custom message is mandatory. |
| Subject | Subject of the custom message. The subject may contain macros. It is limited to 255 characters. |
| Message | The custom message. The message may contain macros. It is limited to certain amount of characters depending on the type of database (see Sending message for more information). |
| Operation type: re- mote com- mand | |
| Target list | Select targets to execute the command on: Current host - command is executed on the host of the trigger that caused the problem event. This option will not work if there are multiple hosts in the trigger. Host - select host(s) to execute the command on. Host group - select host group(s) to execute the command on. Specifying a parent host group implicitly selects all nested host groups. Thus the remote command will also be executed on hosts from nested groups. A command on a host is executed only once, even if the host matches more than once (e.g. from several host groups; individually and from a host group). The target list is meaningless if a custom script is executed on Zabbix server. Selecting more targets in this case only results in the script being executed on the server more times. Note that for global scripts, the target selection also depends on the <i>Host group</i> setting in global script configuration . <i>Target list</i> option is not available for <i>Service actions</i> because in this case remote commands are always executed on Zabbix server. |
| Conditions | Condition for performing the operation: Event is not acknowledged - only when the event is unacknowledged. Event is acknowledged - only when the event is acknowledged. <i>Conditions</i> option is only available for <i>Trigger actions</i> . |

When done, click *Add* to add the operation to the list of *Operations*.

1 Sending message

Overview

Sending a message is one of the best ways of notifying people about a problem. That is why it is one of the primary actions offered by Zabbix.

Configuration

To be able to send and receive notifications from Zabbix you have to:

- **define the media** to send a message to

If the operation takes place outside of the **When active** time period defined for the selected media in the user configuration, the message will not be sent.

The default trigger severity ('Not classified') **must be** checked in user media **configuration** if you want to receive notifications for non-trigger events such as discovery, active agent autoregistration or internal events.

- **configure an action operation** that sends a message to one of the defined media

Attention:

Zabbix sends notifications only to those users that have at least 'read' permissions to the host that generated the event. At least one host of a trigger expression must be accessible.

You can configure custom scenarios for sending messages using **escalations**.

To successfully receive and read emails from Zabbix, email servers/clients must support standard 'SMTP/MIME email' format since Zabbix sends UTF-8 data (If the subject contains ASCII characters only, it is not UTF-8 encoded.). The subject and the body of the message are base64-encoded to follow 'SMTP/MIME email' format standard.

Message limit after all macros expansion is the same as message limit for **Remote commands**.

Tracking messages

You can view the status of messages sent in *Monitoring → Problems*.

In the *Actions* column you can see summarized information about actions taken. In there green numbers represent messages sent, red ones - failed messages. *In progress* indicates that an action is initiated. *Failed* informs that no action has executed successfully.

If you click on the event time to view event details, you will be able to see details of messages sent (or not sent) due to the event in the *Actions* block.

In *Reports → Action log* you will see details of all actions taken for those events that have an action configured.

2 Remote commands

Overview

With remote commands you can define that a certain pre-defined command is automatically executed on the monitored host upon some condition.

Thus remote commands are a powerful mechanism for smart pro-active monitoring.

In the most obvious uses of the feature you can try to:

- Automatically restart some application (web server, middleware, CRM) if it does not respond
- Use IPMI 'reboot' command to reboot some remote server if it does not answer requests
- Automatically free disk space (removing older files, cleaning /tmp) if running out of disk space
- Migrate a VM from one physical box to another depending on the CPU load
- Add new nodes to a cloud environment upon insufficient CPU (disk, memory, whatever) resources

Configuring an action for remote commands is similar to that for sending a message, the only difference being that Zabbix will execute a command instead of sending a message.

Remote commands can be executed by Zabbix server, proxy or agent. Remote commands on Zabbix agent can be executed directly by Zabbix server or through Zabbix proxy. Both on Zabbix agent and Zabbix proxy remote commands are disabled by default. They can be enabled by:

- adding an `AllowKey=system.run[*]` parameter in agent configuration;
- setting the `EnableRemoteCommands` parameter to '1' in proxy configuration.

Remote commands executed by Zabbix server are run as described in **Command execution** including exit code checking.

Remote commands are executed even if the target host is in maintenance.

Remote command limit

Remote command limit after resolving all macros depends on the type of database and character set (non-ASCII characters require more than one byte to be stored):

| Database | Limit in characters | Limit in bytes |
|----------------------------|---------------------|----------------|
| MySQL | 65535 | 65535 |
| PostgreSQL | 65535 | not limited |
| SQLite (only Zabbix proxy) | 65535 | not limited |

Remote command execution output (return value) is limited to 16MB (including trailing whitespace that is truncated). **IPMI remote command** limit is based on the installed IPMI library. Note that **database limits** apply to all remote commands.

Configuration

Those remote commands that are executed on Zabbix agent (custom scripts) must be first enabled in the agent **configuration**.

Make sure that the `AllowKey=system.run[<command>,*]` parameter is added for each allowed command in agent configuration to allow specific command with `nowait` mode. Restart agent daemon if changing this parameter.

Then, when configuring a new action in **Alerts** → **Actions** → **Trigger actions**:

1. Define the appropriate conditions, for example, set that the action is activated upon any disaster problems with one of Apache applications.

Predefined scripts

Scripts that are available for action operations (webhook, script, SSH, Telnet, IPMI) are defined in **global scripts**.

For example:

```
sudo /etc/init.d/apache restart
```

In this case, Zabbix will try to restart an Apache process. With this command, make sure that the command is executed on Zabbix agent (click the *Zabbix agent* button against *Execute on*).

Attention:

Note the use of **sudo** - Zabbix user does not have permissions to restart system services by default. See below for hints on how to configure **sudo**.

Note:

Starting with Zabbix agent 7.0, remote commands can also be executed on an agent that is operating in active mode. Zabbix agent - whether active or passive - should run on the remote host, and executes the commands in background.

Remote commands on Zabbix agent are executed without timeout by the `system.run[,nowait]` key and are not checked for execution results. On Zabbix server and Zabbix proxy, remote commands are executed with timeout as set in the `TrapperTimeout` parameter of `zabbix_server.conf` or `zabbix_proxy.conf` file and are **checked** for execution results. For additional information, see *Script timeout*.

Access permissions

Make sure that the 'zabbix' user has execute permissions for configured commands. One may be interested in using **sudo** to give access to privileged commands. To configure access, execute as root:

```
visudo
```

Example lines that could be used in *sudoers* file:

```
# allows 'zabbix' user to run all commands without password.
zabbix ALL=NOPASSWD: ALL
```

```
# allows 'zabbix' user to restart apache without password.
zabbix ALL=NOPASSWD: /etc/init.d/apache restart
```

Note:

On some systems *sudoers* file will prevent non-local users from executing commands. To change this, comment out **requiretty** option in */etc/sudoers*.

Remote commands with multiple interfaces

If the target system has multiple interfaces of the selected type (Zabbix agent or IPMI), remote commands will be executed on the default interface.

It is possible to execute remote commands via SSH and Telnet using another interface than the Zabbix agent one. The available interface to use is selected in the following order:

- Zabbix agent default interface
- SNMP default interface
- JMX default interface
- IPMI default interface

IPMI remote commands

For IPMI remote commands the following syntax should be used:

```
<command> [<value>]
```

where

- `<command>` - one of IPMI commands without spaces
- `<value>` - 'on', 'off' or any unsigned integer. `<value>` is an optional parameter.

Examples

Examples of **global scripts** that may be used as remote commands in action operations.

Example 1

Restart of Windows on certain condition.

In order to automatically restart Windows upon a problem detected by Zabbix, define the following script:

| Script parameter | Value |
|------------------|--|
| <i>Scope</i> | 'Action operation' |
| <i>Type</i> | 'Script' |
| <i>Command</i> | c:\windows\system32\shutdown.exe -r -f |

Example 2

Restart the host by using IPMI control.

| Script parameter | Value |
|------------------|--------------------|
| <i>Scope</i> | 'Action operation' |
| <i>Type</i> | 'IPMI' |
| <i>Command</i> | reset |

Example 3

Power off the host by using IPMI control.

| Script parameter | Value |
|------------------|--------------------|
| <i>Scope</i> | 'Action operation' |
| <i>Type</i> | 'IPMI' |
| <i>Command</i> | power off |

3 Additional operations

Overview

In this section you may find some details of **additional operations** for discovery/autoregistration events.

Adding host

Hosts are added during the discovery process, as soon as a host is discovered, rather than at the end of the discovery process.

Note:

As network discovery can take some time due to many unavailable hosts/services having patience and using reasonable IP ranges is advisable.

When adding a host, its name is decided by the standard **gethostbyname** function. If the host can be resolved, resolved name is used. If not, the IP address is used. Besides, if IPv6 address must be used for a host name, then all ":" (colons) are replaced by "_" (underscores), since colons are not allowed in host names.

Attention:

If performing discovery by a proxy, currently hostname lookup still takes place on Zabbix server.

Attention:

If a host already exists in Zabbix configuration with the same name as a newly discovered one, Zabbix will add **_N** to the hostname, where **N** is increasing number, starting with 2.

4 Using macros in messages

Overview

In message subjects and message text you can use macros for more efficient problem reporting.

In addition to a number of built-in macros, **user macros** and **expression macros** are also supported. A **full list of macros** supported by Zabbix is available.

Examples

Examples here illustrate how you can use macros in messages.

Example 1

Message subject:

Problem: {TRIGGER.NAME}

When you receive the message, the message subject will be replaced by something like:

Problem: Processor load is too high on Zabbix server

Example 2

Message:

Processor load is: {?last(/zabbix.zabbix.com/system.cpu.load[,avg1])}

When you receive the message, the message will be replaced by something like:

Processor load is: 1.45

Example 3

Message:

Latest value: {?last(/{HOST.HOST}/{ITEM.KEY})}

MAX for 15 minutes: {?max(/{HOST.HOST}/{ITEM.KEY},15m)}

MIN for 15 minutes: {?min(/{HOST.HOST}/{ITEM.KEY},15m)}

When you receive the message, the message will be replaced by something like:

Latest value: 1.45

MAX for 15 minutes: 2.33

MIN for 15 minutes: 1.01

Example 4

Message:

http://<server_ip_or_name>/zabbix/tr_events.php?triggerid={TRIGGER.ID}&eventid={EVENT.ID}

When you receive the message, it will contain a link to the *Event details* page, which provides information about the event, its trigger, and a list of latest events generated by the same trigger.

Example 5

Informing about values from several hosts in a trigger expression.

Message:

Problem name: {TRIGGER.NAME}

Trigger expression: {TRIGGER.EXPRESSION}

1. Item value on {HOST.NAME1}: {ITEM.VALUE1} ({ITEM.NAME1})

2. Item value on {HOST.NAME2}: {ITEM.VALUE2} ({ITEM.NAME2})

When you receive the message, the message will be replaced by something like:

Problem name: Processor load is too high on a local host

Trigger expression: last(/Myhost/system.cpu.load[percpu,avg1])>5 or last(/Myotherhost/system.cpu.load[percpu,avg1])>5

1. Item value on Myhost: 0.83 (Processor load (1 min average per core))

2. Item value on Myotherhost: 5.125 (Processor load (1 min average per core))

Example 6

Receiving details of both the problem event and recovery event in a **recovery** message:

Message:

Problem:

Event ID: {EVENT.ID}

Event value: {EVENT.VALUE}

Event status: {EVENT.STATUS}

Event time: {EVENT.TIME}

Event date: {EVENT.DATE}

Event age: {EVENT.AGE}

Event acknowledgment: {EVENT.ACK.STATUS}

Event update history: {EVENT.UPDATE.HISTORY}

Recovery:

Event ID: {EVENT.RECOVERY.ID}

Event value: {EVENT.RECOVERY.VALUE}

Event status: {EVENT.RECOVERY.STATUS}
Event time: {EVENT.RECOVERY.TIME}
Event date: {EVENT.RECOVERY.DATE}
Operational data: {EVENT.OPDATA}

When you receive the message, the macros will be replaced by something like:

Problem:

Event ID: 21874
Event value: 1
Event status: PROBLEM
Event time: 13:04:30
Event date: 2018.01.02
Event age: 5m
Event acknowledgment: Yes
Event update history: 2018.01.02 13:05:51 "John Smith (Admin)"
Actions: acknowledged.

Recovery:

Event ID: 21896
Event value: 0
Event status: OK
Event time: 13:10:07
Event date: 2018.01.02
Operational data: Current value is 0.83

3 Recovery operations

Overview

Recovery operations allow you to be notified when problems are resolved.

Both messages and remote commands are supported in recovery operations. While several operations can be added, escalation is not supported - all operations are assigned to a single step and therefore will be performed simultaneously.

Use cases

Some use cases for recovery operations are as follows:

1. Notify on a recovery all users that were notified on the problem:
 - Select *Notify all involved* as operation type.
2. Have multiple operations upon recovery: send a notification and execute a remote command:
 - Add operation types for sending a message and executing a command.
3. Open a ticket in external helpdesk/ticketing system and close it when the problem is resolved:
 - Create an external script that communicates with the helpdesk system.
 - Create an action having operation that executes this script and thus opens a ticket.
 - Have a recovery operation that executes this script with other parameters and closes the ticket.
 - Use the {EVENT.ID} macro to reference the original problem.

Configuring a recovery operation

To configure a recovery operation, go to the *Operations* tab in **action** configuration.

Three operation types are available for recovery events:

- **Send message** - send recovery message to specified user;
- **Notify all involved** - send recovery message to all users who were notified on the problem event;
- **<remote command name>** - execute a remote command. Commands are available for execution if previously defined in [global scripts](#) with *Action operation* selected as its scope.

Parameters for each operation type are described below. All mandatory input fields are marked with a red asterisk. When done, click on *Add* to add operation to the list of *Recovery operations*.

Note:

Note that if the same recipient is defined in several operation types without specified *Custom message*, duplicate notifications are not sent.

Operation type: **send message**

| Parameter | Description |
|----------------------------|---|
| <i>Send to user groups</i> | Select user groups to send the recovery message to. The user group must have at least "read" permissions to the host in order to be notified. |
| <i>Send to users</i> | Select users to send the recovery message to. The user must have at least "read" permissions to the host in order to be notified. |
| <i>Send to media type</i> | Send default recovery message to all available (configured and enabled) media types or a specific one only. |
| <i>Custom message</i> | If selected, a custom message can be defined. |
| <i>Subject</i> | Subject of the custom message. The subject may contain macros. |
| <i>Message</i> | The custom message. The message may contain macros. |

Operation type: **remote command**

| Parameter | Description |
|--------------------|--|
| <i>Target list</i> | <p>Select targets to execute the command on:</p> <p>Current host - command is executed on the host of the trigger that caused the problem event. This option will not work if there are multiple hosts in the trigger.</p> <p>Host - select host(s) to execute the command on.</p> <p>Host group - select host group(s) to execute the command on. Specifying a parent host group implicitly selects all nested host groups. Thus the remote command will also be executed on hosts from nested groups.</p> <p>A command on a host is executed only once, even if the host matches more than once (e.g. from several host groups; individually and from a host group).</p> <p>The target list is meaningless if the command is executed on Zabbix server. Selecting more targets in this case only results in the command being executed on the server more times.</p> <p>Note that for global scripts, the target selection also depends on the <i>Host group</i> setting in global script configuration.</p> |

Operation type: notify all involved

| Parameter | Description |
|-----------------------|--|
| <i>Custom message</i> | If selected, a custom message can be defined. |
| <i>Subject</i> | Subject of the custom message. The subject may contain macros. |
| <i>Message</i> | The custom message. The message may contain macros. |

4 Update operations

Overview

Update operations are available in actions with the following event sources:

- *Triggers* - when problems are **updated** by other users, i.e. commented upon, acknowledged, severity has been changed, closed (manually);
- *Services* - when the severity of a service has changed but the service is still not recovered.

Please note that users do not receive notifications about their own updates.

Both messages and remote commands are supported in update operations. While several operations can be added, escalation is not supported - all operations are assigned to a single step and therefore will be performed simultaneously.

Configuring an update operation

To configure an update operation go to the *Operations* tab in action **configuration**.

Update operations offer the same set of parameters as **Recovery operations**.

5 Escalations

Overview

With escalations you can create custom scenarios for sending notifications or executing remote commands.

In practical terms it means that:

- Users can be informed about new problems immediately.
- Notifications can be repeated until the problem is resolved.
- Sending a notification can be delayed.
- Notifications can be escalated to another "higher" user group.
- Remote commands can be executed immediately or when a problem is not resolved for a lengthy period.

Actions are escalated based on the **escalation step**. Each step has a duration in time.

You can define both the default duration and a custom duration of an individual step. The minimum duration of one escalation step is 60 seconds.

You can start actions, such as sending notifications or executing commands, from any step. Step one is for immediate actions. If you want to delay an action, you can assign it to a later step. For each step, several actions can be defined.

The number of escalation steps is not limited.

Escalations are defined when **configuring an operation**. Escalations are supported for problem operations only, not recovery.

Miscellaneous aspects of escalation behavior

Let's consider what happens in different circumstances if an action contains several escalation steps.

| Situation | Behavior |
|---|---|
| <i>The host in question goes into maintenance after the initial problem notification is sent</i> | Depending on the <i>Pause operations for suppressed problems</i> setting in action configuration , all remaining escalation steps are executed either with a delay caused by the maintenance period or without delay. A maintenance period does not cancel operations. |
| <i>The time period defined in the Time period action condition ends after the initial notification is sent</i> | All remaining escalation steps are executed. The <i>Time period</i> condition cannot stop operations; it has effect with regard to when actions are started/not started, not operations. |
| <i>A problem starts during maintenance and continues (is not resolved) after maintenance ends</i> | Depending on the <i>Pause operations for suppressed problems</i> setting in action configuration , all escalation steps are executed either from the moment maintenance ends or immediately. |
| <i>A problem starts during a no-data maintenance and continues (is not resolved) after maintenance ends</i> | It must wait for the trigger to fire, before all escalation steps are executed. |
| <i>Different escalations follow in close succession and overlap</i> | The execution of each new escalation supersedes the previous escalation, but for at least one escalation step that is always executed on the previous escalation. This behavior is relevant in actions upon events that are created with EVERY problem evaluation of the trigger. |
| <i>During an escalation in progress (like a message being sent), based on any type of event: - the action is disabled - Based on trigger event: - the trigger is disabled - the host or item is disabled - Based on internal event about triggers: - the trigger is disabled - Based on internal event about items/low-level discovery rules: - the item is disabled - the host is disabled</i> | The message in progress is sent and then one more message on the escalation is sent. The follow-up message will have the cancellation text at the beginning of the message body (NOTE: Escalation canceled) naming the reason (for example, NOTE: Escalation canceled: action '<Action name>' disabled). This way the recipient is informed that the escalation is canceled and no more steps will be executed. This message is sent to all who received the notifications before. The reason of cancellation is also logged to the server log file (starting from Debug Level 3=Warning). |
| <i>During an escalation in progress (like a message being sent) the action is deleted</i> | Note that the <i>Escalation canceled</i> message is also sent if operations are finished, but recovery operations are configured and are not executed yet. No more messages are sent. The information is logged to the server log file (starting from Debug Level 3=Warning), for example: escalation canceled: action id:334 deleted |

Escalation examples

Example 1

Sending a repeated notification once every 30 minutes (5 times in total) to a "MySQL Administrators" group. To configure:

- In *Operations* tab, set the *Default operation step duration* to "30m" (30 minutes).
- Set the escalation *Steps* to be from "1" to "5".
- Select the "MySQL Administrators" group as the recipients of the message.

New action

Action Operations 1

* Default operation step duration 30m

| Operations | Steps | Details | Start in | Duration | Action |
|------------|-------|---|-------------|----------|---|
| | 1 - 5 | Send message to user groups: MySQL Administrators via Email | Immediately | Default | Edit Remove |

[Add](#)

Notifications will be sent at 0:00, 0:30, 1:00, 1:30, 2:00 hours after the problem starts (unless, of course, the problem is resolved sooner).

If the problem is resolved and a recovery message is configured, it will be sent to those who received at least one problem message within this escalation scenario.

Note:

If the trigger that generated an active escalation is disabled, Zabbix sends an informative message about it to all those that have already received notifications.

Example 2

Sending a delayed notification about a long-standing problem. To configure:

- In *Operations* tab, set the *Default operation step duration* to "10h" (10 hours).
- Set the escalation *Steps* to be from "2" to "2".

New action

Action Operations 1

* Default operation step duration 10h

| Operations | Steps | Details | Start in | Duration | Action |
|------------|-------|---|----------|----------|---|
| | 2 | Send message to user groups: Managers via SMS | 10:00:00 | Default | Edit Remove |

[Add](#)

A notification will only be sent at Step 2 of the escalation scenario, or 10 hours after the problem starts.

You can customize the message text to something like "The problem is more than 10 hours old".

Example 3

Escalating the problem to the Boss.

In the first example above we configured periodical sending of messages to MySQL administrators. In this case, the administrators will get four messages before the problem will be escalated to the Database manager. Note that the manager will get a message only in case the problem is not acknowledged yet, supposedly no one is working on it.

New action

Action Operations 2

* Default operation step duration 30m

| Operations | Steps | Details | Start in | Duration | Action |
|------------|-------|---|-------------|----------|---|
| | 1 - 0 | Send message to user groups: MySQL Administrators via Email | Immediately | Default | Edit Remove |
| | 5 | Send message to users: Database manager (JS) via all media | 02:00:00 | Default | Edit Remove |

Add

Add

Cancel

Note the use of {ESC.HISTORY} macro in the customized message. The macro will contain information about all previously executed steps on this escalation, such as notifications sent and commands executed.

Example 4

A more complex scenario. After multiple messages to MySQL administrators and escalation to the manager, Zabbix will try to restart the MySQL database. It will happen if the problem exists for 2:30 hours and it hasn't been acknowledged.

If the problem still exists, after another 30 minutes Zabbix will send a message to all guest users.

If this does not help, after another hour Zabbix will reboot server with the MySQL database (second remote command) using IPMI commands.

New action

| 7 | Send message to user groups: Guests via all media | 03:00:00 | Default | <a>Edit <a>Remove |
| 9 | Run script "Restart server" on current host | 04:00:00 | Default | <a>Edit <a>Remove |
| <a>Add | | | | |

Example 5

An escalation with several operations assigned to one step and custom intervals used. The default operation step duration is 30 minutes.

New action

Action

Operations 4

* Default operation step duration

30m

Operations

| Steps | Details | Start in | Duration | Action |
|------------|--|-------------|----------|---------------------------|
| 1 - 4 | Send message to user groups: MySQL Administrators via Email | Immediately | Default | <a>Edit <a>Remove |
| 5 - 6 | Send message to users: Database manager (JS) via all media | 02:00:00 | 1h | <a>Edit <a>Remove |
| 5 - 7 | Send message to user groups: Zabbix administrators via Email | 02:00:00 | 10m | <a>Edit <a>Remove |
| 11 | Send message to user groups: Guests via Email | 04:00:00 | Default | <a>Edit <a>Remove |
| <a>Add | | | | |

Notifications will be sent as follows:

- To MySQL administrators at 0:00, 0:30, 1:00, 1:30 after the problem starts.
- To Database manager at 2:00 and 2:10. (and not at 3:00; seeing that steps 5 and 6 overlap with the next operation, the shorter custom step duration of 10 minutes in the next operation overrides the longer step duration of 1 hour tried to set here).
- To Zabbix administrators at 2:00, 2:10, 2:20 after the problem starts (the custom step duration of 10 minutes working).
- To guest users at 4:00 hours after the problem start (the default step duration of 30 minutes returning between steps 8 and 11).

3 Receiving notification on unsupported items

Overview

It is possible to receive notifications on unsupported items in Zabbix.

It is part of the concept of internal events in Zabbix, allowing users to be notified on these occasions. **Internal events** reflect a change of state:

- when items go from 'normal' to 'unsupported' (and back);
- when triggers go from 'normal' to 'unknown' (and back);
- when low-level discovery rules go from 'normal' to 'unsupported' (and back).

This section presents a how-to for **receiving notification** when an item turns unsupported.

Configuration

Overall, the process of setting up the notification should feel familiar to those who have set up alerts in Zabbix before.

Step 1

Configure **some media**, such as email, SMS, or script to use for the notifications. Refer to the corresponding sections of the manual to perform this task.

Attention:

For notifying on internal events the default severity ('Not classified') is used, so leave it checked when configuring **user media** if you want to receive notifications for internal events.

Step 2

Go to *Alerts* → *Actions* → *Internal actions*.

Click on *Create action* at the top right corner of the page to open an action configuration form.

Step 3

In the *Action* tab enter a name for the action. Then click on *Add* in the *Conditions* block to add a new condition.

The screenshot shows the 'New action' configuration form with the 'Action' tab selected. The 'Name' field contains 'Report not supported items'. Below it, the 'Conditions' block has a table with columns 'Label', 'Name', and 'Action'. An 'Add' button is highlighted in the 'Label' column. The 'Enabled' checkbox is checked. A note at the bottom states: '* At least one operation must exist.' At the bottom right are 'Add' and 'Cancel' buttons.

In the *New condition* pop-up window select "Event type" as the condition type and then select "Item in 'not supported' state" as the event type.

The screenshot shows the 'New condition' pop-up window. The 'Type' dropdown is set to 'Event type'. The 'Operator' is set to 'equals'. The 'Event type' dropdown is set to 'Item in "not supported" state'. At the bottom right are 'Add' and 'Cancel' buttons.

Don't forget to click on *Add* to actually list the condition in the *Conditions* block.

Step 4

In the *Operations* tab, click on *Add* in the *Operations* block to add a new operation.

The screenshot shows the 'New action' configuration form with the 'Operations' tab selected. The 'Default operation step duration' is set to '1h'. Below it, the 'Operations' block has a table with columns 'Steps', 'Details', 'Start in', 'Duration', and 'Action'. An 'Add' button is highlighted in the 'Steps' column. The 'Recovery operations' block has a table with columns 'Details' and 'Action', and an 'Add' button. A note at the bottom states: '* At least one operation must exist.' At the bottom right are 'Add' and 'Cancel' buttons.

Select some recipients of the message (user groups/users) and the media type (or "All") to use for delivery. Check the *Custom message* checkbox if you wish to enter the custom subject/content of the problem message.

And that's it, you're done! Now you can look forward to receiving your first notification from Zabbix if some item turns unsupported.

11 Macros

Overview

Zabbix supports a number of built-in macros which may be used in various situations. These macros are variables, identified by a specific syntax:

{MACRO}

Macros resolve to a specific value depending on the context.

Effective use of macros allows to save time and make Zabbix configuration more transparent.

In one of typical uses, a macro may be used in a template. Thus a trigger on a template may be named "Processor load is too high on {HOST.NAME}". When the template is applied to the host, such as Zabbix server, the name will resolve to "Processor load is too high on Zabbix server" when the trigger is displayed in the Monitoring section.

Macros may be used in item key parameters. A macro may be used for only a part of the parameter, for example `item.key[server_{HOST.HOST}_local]`. Double-quoting the parameter is not necessary as Zabbix will take care of any ambiguous special symbols, if present in the resolved macro.

There are other types of macros in Zabbix.

Zabbix supports the following macros:

- `{MACRO}` - built-in macro (see [full list](#))
- `{<macro>.<func>(<params>)}` - macro [functions](#)
- `{$MACRO}` - [user-defined macro](#), optionally [with context](#)
- `{#MACRO}` - macro for [low-level discovery](#)
- `{?EXPRESSION}` - [expression macro](#)

1 Macro functions

Overview

Macro functions offer the ability to customize [macro](#) values (for example, shorten or extract specific substrings), making them easier to work with.

The syntax of a macro function is:

```
{macro.func(params)}
```

where

- **macro** - the macro to customize;
- **func** - the function to apply (see [supported functions](#));
- **params** - a comma-delimited list of function parameters, which must be **double-quoted** if:
 - start with a space or double quotes;
 - contain closing parentheses or a comma.

For example:

```
{{TIME}}.fmttime(format,time_shift)}  
{{ITEM.VALUE}}.regsub(pattern, output)}  
{{$USERMACRO}}.regsub(pattern, output)}  
{#{LLDMACRO}}.regsub(pattern, output)}
```

Macro functions are supported for:

- [Built-in macros](#)
- [User macros](#)
- [Low-level discovery macros](#)
- [Expression macros](#)

Macro functions can be used in all locations supporting the listed macros. This applies unless explicitly stated that only a macro is expected (for example, when configuring [host macros](#) or low-level discovery rule [filters](#)).

See also: [known issues](#)

A single function per macro is supported; multiple macro functions in chain are not supported.

Note:

Please see [escaping examples](#) for cases when macro functions are used inside other contexts (function, item key, another macro, etc).

Supported functions

The functions are listed without additional information. Click on the function to see the full details.

| Function | Description |
|----------------------------|--|
| btoa | Encoding macro value into Base64 encoding. |
| fmtnum | Number formatting to control the number of digits printed after the decimal point. |
| fmttime | Time formatting. |
| htmldecode | Decoding macro value from HTML encoding. |
| htmlencode | Encoding macro value into HTML encoding. |
| iregsub | Substring extraction by a regular expression match (case-insensitive). |
| lowercase | Transformation of macro value characters into lowercase. |
| regrepl | Replacement of character/substring in macro value. |
| regsub | Substring extraction by a regular expression match (case-sensitive). |
| tr | Transliteration of macro value characters. |
| uppercase | Transformation of macro value characters into uppercase. |
| urldecode | Decoding macro value from URL encoding. |

| Function | Description |
|------------------|---|
| urlencode | Encoding macro value into URL encoding. |

Function details

Optional function parameters are indicated by < >.

btoa

Encoding a macro value into Base64 encoding. Base64 encoding is a method for representing binary data as text, useful for storing and secure transmission of binary content over text-based protocols.

Example:

`{{ITEM.VALUE}.btoa()}}` - will Base64-encode a value like "zabbix" into "emFiYml4"

fmtnum(digits)

Number formatting to control the number of digits printed after the decimal point.

Parameters:

- **digits** - the number of digits after decimal point. Valid range: 0-20. No trailing zeros will be produced.

Examples:

`{{ITEM.VALUE}.fmtnum(2)}` - will return "24.35" from a received value of "24.3483523"

`{{ITEM.VALUE}.fmtnum(0)}` - will return "24" from a received value of "24.3483523"

fmttime(format,<time_shift>)

Time formatting.

Note that this function can be used with macros that resolve to a value in one of the following time formats:

- hh:mm:ss
- yyyy-mm-ddThh:mm:ss[tz] (ISO8601 standard)
- UNIX timestamp

Parameters:

- **format** - mandatory format string, compatible with `strftime` function formatting;
- **time_shift** (optional) - the time shift applied to the time before formatting; should start with `-<N><time_unit>` or `+<N><time_unit>`, where:
 - N - the number of time units to add or subtract;
 - time_unit - h (hour), d (day), w (week), M (month) or y (year).

Comments:

- The `time_shift` parameter supports multistep time operations and may include `/<time_unit>` for shifting to the beginning of the time unit (`/d` - midnight, `/w` - 1st day of the week (Monday), `/M` - 1st day of the month, etc.). Examples: `-1w` - exactly 7 days back; `-1w/w` - Monday of the previous week; `-1w/w+1d` - Tuesday of the previous week.
- Time operations are calculated from left to right without priorities. For example, `-1M/d+1h/w` will be parsed as `((-1M/d)+1h)/w`.

Examples:

`{{TIME}.fmttime(%B)}` - will return "October" from a received value of "12:36:01"

`{{TIME}.fmttime(%d %B,-1M/M)}` - will return "1 September" from a received value of "12:36:01"

htmldecode

Decoding a macro value from HTML encoding.

The following characters are supported:

| Value | Decoded value |
|-------------------------|--------------------|
| <code>&amp;</code> | <code>&</code> |
| <code>&lt;</code> | <code><</code> |
| <code>&gt;</code> | <code>></code> |
| <code>&quot;</code> | <code>"</code> |
| <code>&#039;</code> | <code>'</code> |
| <code>&#39;</code> | <code>'</code> |

regsub(pattern,output)

Substring extraction by a regular expression match (case-sensitive).

Parameters:

- **pattern** - the regular expression to match;
- **output** - the output options. **\1** - **\9** placeholders are supported to capture groups. **\0** returns the matched text.

Comments:

- If there is no match for the regular expression, the function returns nothing;
- If the function pattern is an incorrect regular expression, then the macro evaluates to 'UNKNOWN' (except for low-level discovery macros, in which case the function will be ignored, and the macro will remain unresolved);
- References to non-existent capture groups in the replacement string are replaced with an empty string.

Examples:

```
{{ITEM.VALUE}.regsub("^[0-9]+", "Problem ID: \1")} - will resolve to "Problem ID: 123" if a value like "123"
{{ITEM.VALUE}.regsub("fail|error|fault|problem","ERROR")} - will resolve to "ERROR" if "fail", "error", "fault", "problem"
```

See [more examples](#).

tr(characters,replacement)

Transliteration of macro value characters.

- **characters** - the set of characters to replace;
- **replacement** - the set of positionally corresponding replacement characters.

Examples:

```
{{ITEM.VALUE}.tr(abc, xyz)} - will replace all occurrences of "a" with "x", "b" with "y", "c" with "z"
{{ITEM.VALUE}.tr(abc, xyzq)} - will replace all occurrences of "a" with "x", "b" with "y", "c" with "z", "q" with "q"
{{ITEM.VALUE}.tr(abcde, xyz)} - will replace all occurrences of "a" with "x", "b" with "y", "c" with "z", "d" with "x", "e" with "y"
{{ITEM.VALUE}.tr("\\\\", "\\/")} - will replace all occurrences of backslash with forward slash, single quote with double quote
{{ITEM.VALUE}.tr(A-Z,a-z)} - will convert all letters to lowercase
{{ITEM.VALUE}.tr(0-9a-z,*)} - will replace all numbers and lowercase letters with "*"
{{ITEM.VALUE}.tr(0-9,ab)} - will replace all occurrences of 0 with "a", and replace all occurrences of 1 with "b"
{{ITEM.VALUE}.tr(0-9abcA-L,*)} - will replace all numbers, "abc" characters, and A-L range with "*"
{{ITEM.VALUE}.tr("\n","*")} - will replace end-of-line occurrences with "*"
{{ITEM.VALUE}.tr("e", "\n")} - will replace all "e" with end-of-line
```

To include literal characters:

```
backslash - must be escaped as \\
single quote - must be escaped as \'
double quote - must be escaped as \"
```

Supported escape sequences with backslash:

```
\\\\ => \\ - double backslash to single backslash
\\a  => \a - alert
\\b  => \b - backspace
\\f  => \f - form feed
\\n  => \n - newline
\\r  => \r - return
\\t  => \t - horizontal tab
\\v  => \v - vertical tab
```

uppercase

Transformation of all macro value characters into uppercase. Works with single-byte character sets (such as ASCII) and does not support UTF-8.

Example:

```
{{ITEM.VALUE}.uppercase()} - will transform a value like "Zabbix Server" into "ZABBIX SERVER" (uppercase)
```

urlencode

Decoding a macro value from URL encoding.

Example:

`{{ITEM.VALUE}.urldecode()}}` - will URL-decode a value like `"%2F"` into `"/"`

`urlencode`

Encoding a macro value into URL encoding.

Example:

`{{ITEM.VALUE}.urlencode()}}` - will URL-encode a character like `"/"` into `"%2F"`

Additional examples

The table below shows more examples of using macro functions.

| Macro function | Received value | Output |
|--|----------------------------|---|
| <code>{{ITEM.VALUE}.regsub("[0-9]+", "Problem")}</code> | 123Log line | Problem |
| <code>{{ITEM.VALUE}.regsub("^[0-9]+", "Problem")}</code> | 123 Log line | Problem |
| <code>{{ITEM.VALUE}.regsub(".*", "Problem ID: \1")}</code> | Log line | Problem ID: |
| <code>{{ITEM.VALUE}.regsub("^(\\w+).*(?:[0-9]+)", "MySQL Problem ID: \1_2 ")}</code> | MySQL crashed errno 123 | Problem ID: MySQL_123 |
| <code>{{ITEM.VALUE}.regsub("([1-9]+", "Problem ID: \1")}</code> | 123 Log line | UNKNOWN (invalid regular expression) |
| <code>{{#IFALIAS}.regsub("(.*)_[0-9]+", \1)}</code> | customername_1 | customername |
| <code>{{#IFALIAS}.regsub("(.*)_[0-9]+", \2)}</code> | customername_11 | |
| <code>{{#IFALIAS}.regsub("(.*)_[0-9]+", \1)}</code> | customername_1 | <code>{{#IFALIAS}.regsub("(.*)_[0-9]+", \1)}</code> (invalid regular expression) |
| <code>`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \1)}</code> | customername_1 | <code>`\${MACRO}`:customername</code> |
| <code>`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \2)}</code> | customername_1 | <code>`\${MACRO}`:"1"</code> |
| <code>`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \1)}</code> | customername_1 | <code>`\${MACRO}`:{{#M}.regsub("\\(.*)_[0-9]+", \1)}</code> (invalid regular expression) |
| <code>"`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \1)}"</code> | customername_1 | <code>`\${MACRO}`:"customername\"</code> |
| <code>"`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \2)}"</code> | customername_1 | <code>`\${MACRO}`:"1\"</code> |
| <code>"`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \1)}"</code> | customername_1 | <code>`\${MACRO}`:{{#IFALIAS}.regsub("\\(.*)_[0-9]+", \1)}"</code> (invalid regular expression) |

Seeing full item values

Long values of resolved `{ITEM.VALUE}` and `{ITEM.LASTVALUE}` macros for text/log items are truncated to 20 characters in some frontend locations. To see the full values of these macros you may use macro functions, e.g.:

```
{{ITEM.VALUE}.regsub("(.*)", \1)}
{{ITEM.LASTVALUE}.regsub("(.*)", \1)}
```

See also: `{ITEM.VALUE}` and `{ITEM.LASTVALUE}` [macro details](#).

2 User macros

Overview

User macros are supported in Zabbix for greater flexibility, in addition to the macros [supported](#) out-of-the-box.

User macros can be defined on global, template and host level. These macros have a special syntax:

``${MACRO}``

Zabbix resolves macros according to the following precedence:

1. host level macros (checked first)
2. macros defined for first level templates of the host (i.e., templates linked directly to the host), sorted by template ID

3. macros defined for second level templates of the host, sorted by template ID
4. macros defined for third level templates of the host, sorted by template ID, etc.
5. global macros (checked last)

In other words, if a macro does not exist for a host, Zabbix will try to find it in the host templates of increasing depth. If still not found, a global macro will be used, if exists.

Warning:

If a macro with the **same name** exists on multiple linked templates of the same level, the macro from the template with the lowest ID will be used. Thus having macros with the same name in multiple templates is a configuration risk.

If Zabbix is unable to find a macro, the macro will not be resolved.

Attention:

Macros (including user macros) are left unresolved in the Configuration section (for example, in the trigger list) by design to make complex configuration more transparent.

User macros can be used in:

- item name
- item key parameter
- item update intervals and flexible intervals
- trigger name and description
- trigger expression parameters and constants (see [examples](#))
- many other locations - see the [full list](#)

Common use cases of global and host macros

- use a global macro in several locations; then change the macro value and apply configuration changes to all locations with one click
- take advantage of templates with host-specific attributes: passwords, port numbers, file names, regular expressions, etc.

Note:

It is advisable to use host macros instead of global macros because adding, updating or deleting global macros forces incremental configuration update for all hosts. For more information, see [Passive and active agent checks](#).

Configuration

To define user macros, go to the corresponding location in the frontend:

- for global macros, visit *Administration* → *Macros*
- for host and template level macros, open host or template properties and look for the *Macros* tab

A user macro has the following attributes:

| Macro | Value | | Description |
|-------------------|-------------------------|--|-------------|
| {MYSQL_PASSWORD} | ***** | | description |
| {MYSQL_USERNAME} | ***** | | description |
| {SECRET_PASSWORD} | path/to/secret:password | | description |
| {SECRET_USERNAME} | path/to/secret:username | | description |
| {SNMP_COMMUNITY} | public | | description |
| {WORKING_HOURS} | 1-5,09:00-18:00 | | description |

[Add](#)

| Parameter | Description |
|--------------|---|
| <i>Macro</i> | Macro name. The name must be wrapped in curly brackets and start with a dollar sign. Example: {FRONTEND_URL}. The following characters are allowed in the macro names: A-Z (uppercase only) , 0-9 , _ , . |

| Parameter | Description |
|--------------------|---|
| <i>Value</i> | Macro value. Three value types are supported: Text (default) - plain-text value Secret text - the value is masked with asterisks Vault secret - the value contains a path/query to a vault secret . To change the value type click on the button at the end of the value input field. |
| <i>Description</i> | Maximum length of a user macro value is 2048 characters. Text field used to provide more information about this macro. |

When configuring user macros, **note** the following context-specific behaviors:

- if user macros are used in template items or triggers, consider adding those macros to the template as well (even if they are defined globally); that way, *Text* type macros will work as expected after exporting the template to XML and importing into another system (secret macro values are not **exported**)
- if user macros are used in trigger expressions, those macros will resolve only if referencing a parameter or constant; they will NOT resolve if referencing a host, item key, function, operator, or another trigger expression (secret macros cannot be used in trigger expressions)
- if user macros are used on a host that has a low-level discovery rule with host prototypes, **discovered hosts** will inherit all user macros defined on that host

Examples

Example 1

Use of host-level macro in the "Status of SSH daemon" item key:

```
net.tcp.service[ssh,{SSH_PORT}]
```

This item can be assigned to multiple hosts, providing that the value of **{SSH_PORT}** is defined on those hosts.

Example 2

Use of host-level macro in the "CPU load is too high" trigger:

```
last(/ca_001/system.cpu.load[,avg1])>{$MAX_CPULOAD}
```

Such a trigger would be created on the template, not edited in individual hosts.

Note:

If you want to use the amount of values as the function parameter (for example, **max(/host/key,#3)**), include hash mark in the macro definition like this: **SOME_PERIOD => #3**

Example 3

Use of two macros in the "CPU load is too high" trigger:

```
min(/ca_001/system.cpu.load[,avg1],{$CPULOAD_PERIOD})>{$MAX_CPULOAD}
```

Note that a macro can be used as a parameter of trigger function, in this example function **min()**.

Example 4

Synchronize the agent unavailability condition with the item update interval:

- define **{INTERVAL}** macro and use it in the item update interval;
- use **{INTERVAL}** as parameter of the agent unavailability trigger:

```
nodata(/ca_001/agent.ping,{INTERVAL})=1
```

Example 5

Centralize configuration of working hours:

- create a global **{WORKING_HOURS}** macro equal to 1-5,09:00-18:00;
- use it in the *Working time* field in *Administration* → *General* → *GUI*;
- use it in the *When active* field in *Users* → *Users, Media* tab of a user;
- use it to set up more frequent item polling during working hours:

Update interval

Custom intervals

| Type | Interval | Period |
|----------|------------|--|
| Flexible | Scheduling | <input type="text" value="{ \$SHORT_INTERVAL }"/> <input type="text" value="{ \$WORKING_HOURS }"/> |

- use it in the *Time period* action condition;
- adjust the working time in *Administration* → *Macros*, if needed.

Example 6

Use host prototype macro to configure items for discovered hosts:

- on a host prototype define user macro { \$SNMPVALUE } with { #SNMPVALUE } **low-level discovery** macro as a value:

Host prototype macros

Inherited and host prototype macros

| Macro | Value |
|--|--|
| <input type="text" value="{ \$SNMPVALUE }"/> | <input type="text" value="{ #SNMPVALUE }"/> <input type="button" value="T"/> |

Add

Add

Cancel

- assign *Generic SNMPv2* template to the host prototype;
- use { \$SNMPVALUE } in the *SNMP OID* field of *Generic SNMPv2* template items.

User macro context

See **user macros with context**.

3 User macros with context

Overview

An optional context can be used in **user macros**, allowing to override the default value with a context-specific one.

The context is appended to the macro name; the syntax depends on whether the context is a static text value:

{ \$MACRO:"static text" }

or a regular expression:

{ \$MACRO:regex:"regular expression" }

Note that a macro with regular expression context can only be defined in user macro configuration. If the `regex:` prefix is used elsewhere as user macro context, like in a trigger expression, it will be treated as static context.

Context quoting is optional (see also **important notes**).

Macro context examples:

| Example | Description |
|--|--|
| { \$LOW_SPACE_LIMIT } | User macro without context. |
| { \$LOW_SPACE_LIMIT:/tmp } | User macro with context (static string). |
| { \$LOW_SPACE_LIMIT:regex:"~/tmp\$" } | User macro with context (regular expression). Same as { \$LOW_SPACE_LIMIT:/tmp }. |
| { \$LOW_SPACE_LIMIT:regex:"~/var/log/.*\$" } | User macro with context (regular expression). Matches all strings prefixed with /var/log/. |

Use cases

User macros with context can be defined to accomplish more flexible thresholds in trigger expressions (based on the values retrieved by low-level discovery). For example, you may define the following macros:

- `{ $LOW_SPACE_LIMIT } = 10`
- `{ $LOW_SPACE_LIMIT:/home } = 20`
- `{ $LOW_SPACE_LIMIT:regex:"^[a-z]+$" } = 30`

Then a low-level discovery macro may be used as macro context in a trigger prototype for mounted file system discovery:

```
last(/host/vfs.fs.size[{#FSNAME},pfree])<{$LOW_SPACE_LIMIT:"{#FSNAME}"}
```

After the discovery different low-space thresholds will apply in triggers depending on the discovered mount points or file system types. Problem events will be generated if:

- /home folder has less than 20% of free disk space
- folders that match the regexp pattern (like /etc, /tmp or /var) have less than 30% of free disk space
- folders that don't match the regexp pattern and are not /home have less than 10% of free disk space

Important notes

- If more than one user macro with context exists, Zabbix will try to match the simple context macros first and then context macros with regular expressions in an undefined order.

Warning:

Do not create different context macros matching the same string to avoid undefined behavior.

- If a macro with its context is not found on host, linked templates or globally, then the macro without context is searched for.
- Only low-level discovery macros are supported in the context. Any other macros are ignored and treated as plain text.

Technically, macro context is specified using rules similar to **item key** parameters, except macro context is not parsed as several parameters if there is a `,` character:

- Macro context must be quoted with `"` if the context contains a `}` character or starts with a `"` character. Quotes inside quoted context must be escaped with the `\` character.
- The `\` character itself is not escaped, which means it's impossible to have a quoted context ending with the `\` character - the macro `{ $MACRO:"a:\b\c" }` is invalid.
- The leading spaces in context are ignored, the trailing spaces are not:
 - For example `{ $MACRO:A }` is the same as `{ $MACRO: A }`, but not `{ $MACRO:A }`.
- All spaces before leading quotes and after trailing quotes are ignored, but all spaces inside quotes are not:
 - Macros `{ $MACRO:"A" }`, `{ $MACRO: "A" }`, `{ $MACRO:"A" }` and `{ $MACRO: "A" }` are the same, but macros `{ $MACRO:"A" }` and `{ $MACRO:" A " }` are not.

The following macros are all equivalent, because they have the same context: `{ $MACRO:A }`, `{ $MACRO: A }` and `{ $MACRO:"A" }`. This is in contrast with item keys, where `'key[a]'`, `'key[a]'` and `'key["a"]'` are the same semantically, but different for uniqueness purposes.

4 Secret user macros

Overview

Zabbix provides two options for protecting sensitive information in user macro values:

- Secret text
- Vault secret

Note:

While the value of a secret macro is hidden, it can be revealed through use in items. For example, in an external script, an `echo` statement referencing a secret macro may be used to reveal the macro value to the frontend, because Zabbix server has access to the real macro value. See **locations** where secret macro values are unmasked.

Secret macros cannot be used in trigger expressions.

Secret text

With Secret text macros, the macro value is masked with asterisks.

To make a macro value secret, click on the button at the end of the *Value* field and select the *Secret text* option:

| Value | Description |
|-------|-------------|
| | description |

Once the configuration is saved, it will no longer be possible to view the value.

To change the macro value, hover over the *Value* field and click the *Set new value* button (appears on hover):

Set new value

When you click the *Set new value* button (or change the macro value type), the current value will be erased. You can restore the original value by clicking the arrow at the end of the *Value* field (only available before saving the new configuration). Note that restoring the original value will not expose it.

Note:

URLs that contain a secret macro will not work, as the macro in them will be resolved as "*****".

Vault secret

With Vault secret macros, the macro value is stored in an external secret management software (vault).

To configure a Vault secret macro, click on the button at the end of the *Value* field and select the *Vault secret* option:

| Value | Description |
|------------------------|-------------|
| secret/zabbix:password | description |

The macro value must point to a vault secret. The input format depends on the vault provider. For provider-specific configuration examples, see:

- [HashiCorp](#)
- [CyberArk](#)

Vault secret macro values are retrieved from the vault by Zabbix server on every refresh of configuration data and then stored in the configuration cache.

Zabbix proxy receives values of Vault secret macros from Zabbix server on each configuration sync and stores them in its own configuration cache. The proxy never retrieves macro values from the vault directly. That means a Zabbix proxy cannot start data collection after a restart until it receives the configuration update from Zabbix server.

To manually refresh secret values from the vault, use the `secrets_reload` **runtime control** option.

Encryption must be enabled between Zabbix server and proxy; otherwise a server warning message is logged.

Warning:

If a macro value cannot be retrieved successfully, the corresponding item using the value will turn unsupported.

Unmasked locations

This list provides locations of parameters where secret macro values are unmasked.

Note:

Since Zabbix 7.2.7, secret macro values will remain masked in the locations below if referenced indirectly. For example, {ITEM.KEY}, {ITEM.KEY<1-9>}, {LLDRULE.KEY} **built-in macros** used in media types (Script or Webhook parameters) will resolve to item keys containing masked secret macros, such as `net.tcp.port[*****,*]*)` instead of `net.tcp.port[192.0.2.0,80]`.

| Context | Parameter |
|--|---|
| Items, item prototypes, LLD rules | |
| Item | <i>Item key parameters</i> |
| Item prototype | <i>Item prototype key parameters</i> |
| Low-level discovery rule | <i>Discovery item key parameters</i> |
| SNMP agent | <i>SNMP community</i> <i>Context name (SNMPv3)</i> <i>Security name (SNMPv3)</i> <i>Authentication passphrase (SNMPv3)</i> <i>Privacy passphrase (SNMPv3)</i> |
| HTTP agent | <i>URL</i> <i>Query fields</i> <i>Post</i> <i>Headers</i> <i>User name</i> <i>Password</i> <i>SSL key password</i> |
| Script | <i>Parameters</i> <i>Script</i> |
| Browser | <i>Parameters</i> <i>Script</i> |
| Database monitor | <i>SQL query</i> |
| TELNET agent | <i>Script</i> <i>User name</i> <i>Password</i> |
| SSH agent | <i>Script</i> <i>User name</i> <i>Password</i> |
| Simple check | <i>User name</i> <i>Password</i> |
| JMX agent | <i>User name</i> <i>Password</i> |
| Item value preprocessing | |
| JavaScript preprocessing step | <i>Script</i> |
| Web scenarios | |
| Web scenario | <i>Variable value</i> <i>Header value</i> <i>URL</i> <i>Query field value</i> <i>Post field value</i> <i>Raw post</i> |
| Web scenario authentication | <i>User</i> <i>Password</i> <i>SSL key password</i> |
| Connectors | |
| Connector | <i>URL</i> <i>Username</i> <i>Password</i> <i>Token</i> <i>HTTP proxy</i> <i>SSL certificate file</i> <i>SSL key file</i> <i>SSL key password</i> |
| Network discovery | |
| SNMP | <i>SNMP community</i> |

| Context | Parameter |
|------------------------|---|
| Global scripts | <i>Context name (SNMPv3)</i> |
| | <i>Security name (SNMPv3)</i> |
| | <i>Authentication passphrase (SNMPv3)</i> |
| | <i>Privacy passphrase (SNMPv3)</i> |
| | |
| | <i>JavaScript script</i> |
| | <i>JavaScript script parameter value</i> |
| | <i>Username</i> |
| | <i>Password</i> |
| | <i>Username</i> |
| Media types | <i>Password</i> |
| | <i>Script</i> |
| | <i>Script parameters</i> |
| | <i>Parameters</i> |
| IPMI management | |
| | <i>Username</i> |
| | <i>Password</i> |

5 Low-level discovery macros

Overview

There is a type of macro used within the **low-level discovery** (LLD) function:

{#MACRO}

It is a macro that is used in an LLD rule and returns real values of the file system name, network interface, SNMP OID, etc.

These macros can be used for creating item, trigger and graph *prototypes*. Then, when discovering real file systems, network interfaces etc., these macros are substituted with real values and are the basis for creating real items, triggers and graphs.

These macros are also used in creating host and host group *prototypes* in virtual machine **discovery**.

Some low-level discovery macros come "pre-packaged" with the LLD function in Zabbix - {#FSNAME}, {#FSTYPE}, {#IFNAME}, {#SNMPINDEX}, {#SNMPVALUE}. However, adhering to these names is not compulsory when creating a **custom** low-level discovery rule. Then you may use any other LLD macro name and refer to that name.

Supported data types

When defining custom discovery rules, property values returned in JSON objects for LLD macros must be one of the following primitive types:

- string;
- number;
- boolean.

Arrays, objects, and null values are not supported. Any LLD macro referring to such a value will remain unexpanded and will appear literally (e.g. '{#MY_MACRO}') during item preprocessing and creation.

Supported locations

LLD macros can be used:

- in the low-level discovery rule filter
- for item prototypes in
 - name
 - key parameters
 - unit
 - update interval¹
 - timeout¹
 - history storage period¹
 - trend storage period¹
 - item value preprocessing steps
 - SNMP OID
 - IPMI sensor field
 - calculated/aggregate item expression, in:

- * expression constants and function parameters
- * item key parameters
- aggregate item filter conditions (host group name and tag name)
- SSH script and Telnet script
- database monitoring SQL query
- JMX item endpoint field
- description
- HTTP agent URL field
- HTTP agent HTTP query fields field
- HTTP agent request body field
- HTTP agent required status codes field
- HTTP agent headers field key and value
- HTTP agent HTTP authentication username field
- HTTP agent HTTP authentication password field
- HTTP agent HTTP proxy field
- HTTP agent HTTP SSL certificate file field
- HTTP agent HTTP SSL key file field
- HTTP agent HTTP SSL key password field
- tags
- for trigger prototypes in
 - name
 - operational data
 - expression (only in constants and function parameters)
 - URL
 - description
 - tags
- for graph prototypes in
 - name
- for host prototypes in
 - name
 - visible name
 - custom interface fields: IP, DNS, port, SNMP v1/v2 community, SNMP v3 context name, SNMP v3 security name, SNMP v3 authentication passphrase, SNMP v3 privacy passphrase
 - host group prototype name
 - host tag value
 - host macro value
 - (see the [full list](#))

In all those places, except the low-level discovery rule filter, LLD macros can be used inside static user **macro context**.

Using macro functions

Macro functions are supported with low-level discovery macros (except in low-level discovery rule **filter**), allowing to extract a certain part of the macro value using a regular expression.

For example, you may want to extract the customer name and interface number from the following LLD macro for the purposes of event tagging:

```
{#IFALIAS}=customername_1
```

To do so, the `regsub` macro function can be used with the macro in the event tag value field of a trigger prototype:

| Trigger prototype | Tags 2 | Dependencies | | | | | | | | | |
|-------------------|--|--|------|-------|--|----------|--|--|-----------|--|--|
| | <div>Trigger tags</div> <div>Inherited and trigger tags</div> | | | | | | | | | | |
| | <table> <thead> <tr> <th>Tags</th><th>Name</th><th>Value</th></tr> </thead> <tbody> <tr> <td></td><td>customer</td><td>{#{IFALIAS}.regsub("(.*)_([0-9]+)", \1)}</td></tr> <tr> <td></td><td>interface</td><td>{#{IFALIAS}.regsub("(.*)_([0-9]+)", \2)}</td></tr> </tbody> </table> | Tags | Name | Value | | customer | {#{IFALIAS}.regsub("(.*)_([0-9]+)", \1)} | | interface | {#{IFALIAS}.regsub("(.*)_([0-9]+)", \2)} | |
| Tags | Name | Value | | | | | | | | | |
| | customer | {#{IFALIAS}.regsub("(.*)_([0-9]+)", \1)} | | | | | | | | | |
| | interface | {#{IFALIAS}.regsub("(.*)_([0-9]+)", \2)} | | | | | | | | | |

Note that commas are not allowed in unquoted item **key parameters**, so the parameter containing a macro function has to be quoted. The backslash (\) character should be used to escape double quotes inside the parameter. Example:

```
net.if.in["{#{IFALIAS}.regsub(\"(.*)_([0-9]+)\", \1)}", bytes]
```

For more information on macro function syntax, see: [Macro functions](#)

Macro functions are supported in low-level discovery macros since Zabbix 4.0.

Footnotes

¹ In the fields marked with ¹ a single macro has to fill the whole field. Multiple macros in a field or macros mixed with text are not supported.

6 Expression macros

Overview

Expression macros are useful for formula calculations. They are calculated by expanding all macros inside and evaluating the resulting expression.

Expression macros have a special syntax:

`{?EXPRESSION}`

The syntax in EXPRESSION is the same as in [trigger expressions](#) (see usage limitations below).

`{FUNCTION.VALUE<1-9>}` and `{FUNCTION.RECOVERY.VALUE<1-9>}` macros can be used to reference function values of the trigger expressions and trigger recovery expressions, for example:

`{?{FUNCTION.VALUE2} - {FUNCTION.VALUE3}}`

`{HOST.HOST<1-9>}` and `{ITEM.KEY<1-9>}` macros can be used inside the functions to reference hosts and items, for example:

`{?max(/{HOST.HOST}/{ITEM.KEY},3h)}`

Usage

In the following locations:

- graph names
- map element labels
- map shape labels
- map link labels

only a **single** function, from the following set: avg, last, max, min, is allowed as an expression macro, e.g.:

`{?avg(/{HOST.HOST}/{ITEM.KEY},1h)}`

Expressions such as `{?last(/host/item1)/last(/host/item2)}`, `{?count(/host/item1,5m)}` and `{?last(/host/item1)*10}` are incorrect in these locations.

However, in:

- trigger event names
- trigger-based notifications and commands
- problem update notifications and commands

complex expressions are allowed, e.g.:

`{?trendavg(/host/item1,1M:now/M)/trendavg(/host/item1,1M:now/M-1y)*100}`

Note:

When using expression macros in templates please do not specify the template name but rather use `{HOST.HOST<N>}`, because template names are not substituted with hosts during linkage. You can also omit host reference altogether for the first host, e.g. `{?avg(/item1,1h)}`

See also:

- [Supported macros](#) for a list of supported locations of the expression macro
- [Example](#) of using an expression macro in the event name

12 Users and user groups

Overview

All user passwords are encrypted and stored in the Zabbix database. Users cannot use their user id and password to log directly into the UNIX server unless they have also been set up accordingly to UNIX. Communication between the web server and the user browser can be protected using SSL.

- access administrative Zabbix frontend functions
- perform certain actions in the frontend
- access monitored hosts in hostgroups
- use specific API methods

Overview

- *Admin* - a Zabbix **superuser** with full permissions.
- *guest* - a special Zabbix **user**. The 'guest' user is disabled by default. If you add it to the Guests user group, you may log in with this user and access monitoring pages in Zabbix. Note that by default, 'guest' has no permissions on Zabbix objects.

- Go to *Users* → *Users*.
- Click on *Create user* (or on a user name to edit an existing user).
- Edit user attributes in the form.

The *User* tab contains general user attributes:

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|--------------------------|--|
| <i>Username</i> | Unique username, used as the login name. |
| <i>Name</i> | User first name (optional). If not empty, visible in acknowledgment information and notification recipient information. |
| <i>Last name</i> | User last name (optional). If not empty, visible in acknowledgment information and notification recipient information. |
| <i>Groups</i> | Select user groups the user belongs to. This field is auto-complete so starting to type the name of a user group will offer a dropdown of matching groups. Scroll down to select. Alternatively, click on <i>Select</i> to add groups. Click on 'x' to remove the selected. Adherence to user groups determines what host groups and hosts the user will have access to . |
| <i>Password</i> | Two fields for entering the user password, or a <i>Change password</i> button if the user already exists. Clicking on the <i>Change password</i> button opens two fields for entering a new password. For the user with the <i>Super admin role</i> changing own password, clicking on the <i>Change password</i> button opens an additional field for entering the current (old) password. On a successful password change, the user for which the password was changed will be logged out of all active sessions. Note that the password can only be changed for users using Zabbix internal authentication . |
| <i>Language</i> | Language of the Zabbix frontend. The php gettext extension is required for the translations to work. |
| <i>Time zone</i> | Select the time zone to override global time zone on user level or select System default to use global time zone settings. |
| <i>Theme</i> | Defines how the frontend looks like: System default - use default system settings Blue - standard blue theme Dark - alternative dark theme High-contrast light - light theme with high contrast High-contrast dark - dark theme with high contrast |
| <i>Auto-login</i> | Mark this checkbox to make Zabbix remember the user and log the user in automatically for 30 days. When logging in with Remember for 30 days : - Auto-logout is reset (session persists for 30 days). - Auto-login is enabled for seamless re-authentication. When logging in without Remember for 30 days : - Auto-login is enabled for seamless re-authentication. - Auto-logout remains governed by the standard timeout setting. Browser cookies are used for this. |
| <i>Auto-logout</i> | With this checkbox marked the user will be logged out automatically, after the set amount of seconds (minimum 90 seconds, maximum 1 day). Note, that this setting is overridden if Remember for 30 days is enabled, as the session is extended for the full period. Time suffixes are supported, e.g. 90s, 5m, 2h, 1d. Note that this option will not work: * If the "Show warning if Zabbix server is down" global configuration option is enabled and Zabbix frontend is kept open. * When Monitoring menu pages perform background information refreshes. * If logging in with the Remember me for 30 days option checked. |
| <i>Refresh</i> | Set the refresh rate used for graphs, plain text data, etc. Can be set to 0 to disable. Time suffixes are supported, e.g. 90s, 5m, 1h. |
| <i>Rows per page</i> | You can determine how many rows per page will be displayed in lists. |
| <i>URL (after login)</i> | You can make Zabbix transfer the user to a specific URL after successful login, for example, to <i>Problems</i> page. |

User media

The *Media* tab contains a listing of all media defined for the user. Media are used for sending notifications.

User

Media 2

Permissions

| Media | Type | Send to | When active | Use if severity | Status | Action |
|-------|---|--------------------|-----------------|--|----------|---|
| | Email  | example@zabbix.com | 1-7,00:00-24:00 |  | Disabled | Edit Remove |
| | Gmail | example@gmail.com | 1-7,00:00-24:00 |  | Enabled | Edit Remove |
| | Add | | | | | |

Click on *Add* to assign media to the user.

If the media type has been disabled:

- A yellow info icon is displayed after the name.
- *Disabled* is displayed in the Status column.

See the [Media types](#) section for details on configuring user media.

Permissions

The *Permissions* tab contains information on the following elements:

- User role (mandatory for any newly created user) that can only be changed by a *Super admin* user.

Attention:

Users cannot be created without a **user role** (except with Zabbix **User API**). Previously created users which do not have a role may still be edited without assigning a role to them. However, once a role is assigned, it can only be changed, not removed.

 Note that users without a role can log into Zabbix only using **LDAP** or **SAML** authentication, provided their LDAP/SAML information matches the user group mappings configured in Zabbix.

- User type (*User*, *Admin*, *Super admin*) that is defined in the user role configuration.
- Host and template groups that the user has access to.
 - *User* and *Admin* type users, by default, do not have access to any groups, templates, and hosts. To grant such access, users must be included in user groups configured with permissions to the relevant entities.
- Access rights to sections and elements of Zabbix frontend, modules, and API methods.
 - Elements with allowed access are displayed in green color, while those with denied access - in light gray color.
- Rights to perform specific actions.
 - Actions that the user is allowed to perform are displayed in green color, while those that are denied - in light gray color.

See the [Permissions](#) page for details.

2 Permissions

Overview

Permissions in Zabbix depend on the user type, customized user roles and access to hosts, which is specified based on the user group.

User types

Permissions in Zabbix depend, primarily, on the user type:

- *User* - has limited access rights to menu sections (see below) and no access to any resources by default. Any permissions to host or template groups must be explicitly assigned;
- *Admin* - has incomplete access rights to menu sections (see below). The user has no access to any host groups by default. Any permissions to host or template groups must be explicitly given;
- *Super admin* - has access to all menu sections. The user has a read-write access to all host and template groups. Permissions cannot be revoked by denying access to specific groups.

Menu access

The following table illustrates access to Zabbix menu sections per user type:

| Menu section | User | Admin | Super admin |
|-------------------|------|-------|-------------|
| Dashboards | + | + | + |
| Monitoring | + | + | + |

| Menu section | | User | Admin | Super admin |
|------------------------|---------------------------------|------|-------|-------------|
| Services | <i>Problems</i> | + | + | + |
| | <i>Hosts</i> | + | + | + |
| | <i>Latest data</i> | + | + | + |
| | <i>Maps</i> | + | + | + |
| | <i>Discovery</i> | | + | + |
| | | + | + | + |
| | <i>Services</i> | + | + | + |
| | <i>SLA</i> | | + | + |
| | <i>SLA report</i> | + | + | + |
| | | + | + | + |
| Inventory | <i>Overview</i> | + | + | + |
| | <i>Hosts</i> | + | + | + |
| Reports | | + | + | + |
| | <i>System information</i> | | | + |
| | <i>Scheduled reports</i> | | + | + |
| | <i>Availability report</i> | + | + | + |
| | <i>Top 100 triggers</i> | + | + | + |
| | <i>Audit log</i> | | | + |
| | <i>Action log</i> | | | + |

User roles

User roles allow making custom adjustments to the permissions defined by the user type. While no permissions can be added (that would exceed those of the user type), some permissions can be revoked.

Furthermore, a user role determines access not only to menu sections, but also to services, modules, API methods and various actions in the frontend.

User roles are configured in the *Users* → *User roles* section by Super admin users.

User roles are assigned to users in the user configuration form, *Permissions* tab, by Super admin users.

Access to hosts

Access to any host and template data in Zabbix is granted to **user groups** on the host/template group level only.

That means that an individual user cannot be directly granted access to a host (or host group). It can only be granted access to a host by being part of a user group that is granted access to the host group that contains the host.

Similarly, a user can only be granted access to a template by being part of a user group that is granted access to the template group that contains the template.

3 User groups

Overview

User groups allow to group users both for organizational purposes and for assigning permissions to data. Permissions to viewing and configuring data of host groups and template groups are assigned to user groups, not individual users.

It may often make sense to separate what information is available for one group of users and what - for another. This can be accomplished by grouping users and then assigning varied permissions to host and template groups.

A user can belong to any number of groups.

Configuration

To configure a user group:

- Go to *Users* → *User groups*
- Click on *Create user group* (or on the group name to edit an existing group)
- Edit group attributes in the form

The **User group** tab contains general group attributes:

The screenshot shows the 'User group' configuration form in Zabbix. The 'User group' tab is selected. The form contains the following fields:

- Group name**: A text input field with a red asterisk indicating it is mandatory. The value is 'Guests'.
- Users**: A searchable list box showing 'guest' with a close button (x). A 'Select' button is to the right.
- Frontend access**: A dropdown menu set to 'Internal'.
- LDAP Server**: A dropdown menu set to 'Default'.
- Multi-factor authentication**: A dropdown menu set to 'Disabled'.
- Enabled**: A checked checkbox.
- Debug mode**: An unchecked checkbox.

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|------------------------------------|---|
| <i>Group name</i> | Unique group name. |
| <i>Users</i> | To add users to the group start typing the name of an existing user. When the dropdown with matching user names appears, scroll down to select. Alternatively you may click the <i>Select</i> button to select users in a popup. |
| <i>Frontend access</i> | How the users of the group are authenticated. System default - use default authentication method (set globally) Internal - use Zabbix internal authentication (even if LDAP authentication is used globally). Ignored if HTTP authentication is the global default. LDAP - use LDAP authentication (even if internal authentication is used globally). Ignored if HTTP authentication is the global default. Disabled - access to Zabbix frontend is forbidden for this group |
| <i>LDAP server</i> | Select which LDAP server to use to authenticate the user. |
| <i>Multi-factor authentication</i> | This field is enabled only if <i>Frontend access</i> is set to LDAP or System default. Select which multi-factor authentication method to use to authenticate the user: Default - use the method set as default in MFA configuration; this option is selected by default for new user groups if MFA is enabled; <Method name> - use selected method (for example, "Zabbix TOTP"); Disabled - MFA is disabled for this group; this option is selected by default for new user groups if MFA is disabled. Note that if a user belongs to multiple user groups with MFA enabled (or at least one group has MFA enabled), the following authentication rules apply: if any group uses the "Default" MFA method, it will authenticate the user; otherwise, the first method (ordered alphabetically) will be used for authentication. |
| <i>Enabled</i> | Status of user group and group members. <i>Checked</i> - user group and users are enabled <i>Unchecked</i> - user group and users are disabled |
| <i>Debug mode</i> | Mark this checkbox to activate debug mode for the users. |

The **Template permissions** tab allows specifying user group access to template group (and thereby template) data:

User groups

User group Template permissions ● Host permissions ● Problem tag filter ●

Permissions

| Template groups | Permissions | Action |
|--|---|------------------------|
| <div>Templates/Applications X</div> <div>type here to search</div> | <div>Select</div> <div>Read-write</div> <div>Read</div> <div>Deny</div> | Remove |
| <div>Templates/Databases X</div> <div>type here to search</div> | <div>Select</div> <div>Read-write</div> <div>Read</div> <div>Deny</div> | Remove |
| <div>Templates/Operating systems X</div> <div>Templates/Server hardware X</div> <div>type here to search</div> | <div>Select</div> <div>Read-write</div> <div>Read</div> <div>Deny</div> | Remove |

[Add](#)

[Update](#) [Delete](#) [Cancel](#)

The **Host permissions** tab allows specifying user group access to host group (and thereby host) data:

User groups

User group Template permissions ● Host permissions ● Problem tag filter ●

Permissions

| Host groups | Permissions | Action |
|---|---|------------------------|
| <div>Discovered hosts X Virtual machines X</div> <div>type here to search</div> | <div>Select</div> <div>Read-write</div> <div>Read</div> <div>Deny</div> | Remove |
| <div>Hypervisors X Linux servers X</div> <div>type here to search</div> | <div>Select</div> <div>Read-write</div> <div>Read</div> <div>Deny</div> | Remove |
| <div>Zabbix servers X</div> <div>type here to search</div> | <div>Select</div> <div>Read-write</div> <div>Read</div> <div>Deny</div> | Remove |

[Add](#)

[Update](#) [Delete](#) [Cancel](#)

Click on [Add](#) to choose the template/host groups (be it a parent or a nested group) and assign permissions to those. Start typing the group name (a dropdown of matching groups will appear) or click on *Select* for a popup window listing all groups to be opened.

Then use the option buttons to assign permissions to the chosen groups. Possible permissions are the following:

- **Read-write** - read-write access to a group;
- **Read** - read-only access to a group;
- **Deny** - access to a group denied.

If the same template/host group is added in several rows with different permissions set, the strictest permission will be applied.

Note that a *Super admin* user can enforce nested groups to have the same level of permissions as the parent group; this can be done in the **host/template** group configuration form.

Template permissions and **Host permissions** tabs support the same set of parameters.

Current permissions to groups are displayed in the *Permissions* block, and those can be modified or removed.

Note:

If a user group has **Read-write** permissions to a host and **Deny** or no permissions to a template linked to this host, the users of such group will not be able to edit templated items on the host, and template name will be displayed as *Inaccessible template*.

The **Problem tag filter** tab allows setting tag-based permissions for user groups to see problems filtered by tag name and value:

User group Template permissions ● Host permissions ● Problem tag filter ●

Permissions

| Host groups | Tags | Action |
|---|--------------------------|---|
| <div>Databases</div> <div>Add</div> | <div>target: mysql</div> | <div>Edit</div> <div>Remove</div> |

[Add](#) [Cancel](#)

Click on [Add](#) to choose the host groups. To select a host group to apply a tag filter for, click *Select* to get the complete list of existing host groups or start typing the name of a host group to get a dropdown of matching groups. Only host groups will be displayed, because problem tag filter cannot be applied to template groups.

Then it is possible to switch from *All tags* to *Tag list* in order to set particular tags and their values for filtering. Tag names without values can be added, but values without names cannot. Only the first three tags (with values, if any) are displayed in the

Permissions block; if there are more, those can be seen by clicking or hovering over the **...** icon.

Tag filter allows separating the access to host group from the possibility to see problems.

For example, if a database administrator needs to see only "MySQL" database problems, it is required to create a user group for database administrators first, then specify "target" tag name and "mysql" value.

New tag filter

* Host groups

Databases X

type here to search

Select

Filter

All tagsTag list

* Tags

TagValueAction

targetmysqlRemove

Add

Add

Cancel

If "target" tag name is specified and value field is left blank, the user group will see all problems with tag name "target" for the selected host group. If *All tags* is selected, the user group will see all problems for the specified host group.

Make sure tag name and tag value are correctly specified, otherwise, the user group will not see any problems.

Let's review an example when a user is a member of several user groups selected. Filtering in this case will use OR condition for tags.

| User group A | | | User group B | | | Visible result for a user (member) of both groups |
|---|------------------|-----------|--------------|----------|-----------|--|
| Tag filter | | | Tag filter | | | |
| Host group | Tag name | Tag value | Host group | Tag name | Tag value | |
| Databases | target | mysql | Databases | target | oracle | target:mysql or target:oracle problems visible |
| Databases | set to: All tags | | Databases | target | oracle | All problems visible |
| Not configured in the Problem tag filter | | | Databases | target | oracle | target:oracle problems visible |

Attention:

Adding a filter (for example, all tags in a certain host group "Databases") results in not being able to see the problems of other host groups.

Access from several user groups

A user may belong to any number of user groups. These groups may have different access permissions to hosts or templates.

Therefore, it is important to know what entities an unprivileged user will be able to access as a result. For example, let us consider how access to host **X** (in Hostgroup 1) will be affected in various situations for a user who is in user groups A and B.

- If Group A has only *Read* access to Hostgroup 1, but Group B *Read-write* access to Hostgroup 1, the user will get **Read-write** access to 'X'.

Attention:

"Read-write" permissions have precedence over "Read" permissions.

- In the same scenario as above, if 'X' is simultaneously also in Hostgroup 2 that is **denied** to Group A or B, access to 'X' will be **unavailable**, despite a *Read-write* access to Hostgroup 1.
- If Group A has no permissions defined and Group B has a *Read-write* access to Hostgroup 1, the user will get **Read-write** access to 'X'.
- If Group A has *Deny* access to Hostgroup 1 and Group B has a *Read-write* access to Hostgroup 1, the user will get access to 'X' **denied**.

Other details

- An Admin level user with *Read-write* access to a host will not be able to link/unlink templates, if he has no access to the template group they belong to. With *Read* access to the template group he will be able to link/unlink templates to the host, however, will not see any templates in the template list and will not be able to operate with templates in other places.
- An Admin level user with *Read* access to a host will not see the host in the configuration section host list; however, the host triggers will be accessible in IT service configuration.
- Any non-Super Admin user (including 'guest') can see network maps as long as the map is empty or has only images. When hosts, host groups or triggers are added to the map, permissions are respected.
- Zabbix server will not send notifications to users defined as action operation recipients if access to the concerned host is explicitly "denied".

13 Storage of secrets

Overview Zabbix can be configured to retrieve sensitive information from a secure vault. The following secret management services are supported: HashiCorp Vault KV Secrets Engine - Version 2, CyberArk Vault CV12.

Secrets can be used for retrieving:

- **user macro values**
- database access credentials

Zabbix provides read-only access to the secrets in a vault, assuming that secrets are managed by someone else.

For information about specific vault provider configuration, see:

- [HashiCorp configuration](#)
- [CyberArk configuration](#)

Caching of secret values Vault secret macro values are retrieved by Zabbix server on every refresh of configuration data and then stored in the configuration cache. Zabbix proxy receives values of vault secret macros from Zabbix server on each configuration sync and stores them in its own configuration cache.

Attention:

Encryption must be enabled between Zabbix server and proxy; otherwise a server warning message is logged.

To manually trigger refresh of cached secret values from a vault, use the 'secrets_reload' command-line **option**.

For Zabbix frontend database credentials caching is disabled by default, but can be enabled by setting the option `$DB['VAULT_CACHE'] = true` in `zabbix.conf.php`. The credentials will be stored in a local cache using the filesystem temporary file directory. The web server must allow writing in a private temporary folder (for example, for Apache the configuration option `PrivateTmp=True` must be set). To control how often the data cache is refreshed/invalidated, use the `ZBX_DATA_CACHE_TTL` **constant**.

TLS configuration To configure TLS for communication between Zabbix components and the vault, add a certificate signed by a certificate authority (CA) to the system-wide default CA store. To use another location, specify the directory in the `SSLCAlocation` Zabbix **server/proxy** configuration parameter, place the certificate file inside that directory, then run the CLI **command**:

```
c_rehash .
```

1 CyberArk configuration

This section explains how to configure Zabbix to retrieve secrets from CyberArk Vault CV12.

The vault should be installed and configured as described in the official [CyberArk documentation](#).

To learn about configuring TLS in Zabbix, see [Storage of secrets](#).

Database credentials

Access to a secret with database credentials is configured for each Zabbix component separately.

Server and proxies

To obtain database credentials from the vault for Zabbix **server** or **proxy**, specify the following configuration parameters in the configuration file:

- **Vault** - which vault provider should be used;
- **VaultURL** - vault server HTTP[S] URL;
- **VaultDBPath** - query to the vault secret containing database credentials which will be retrieved by keys "Content" and "UserName" (this option can only be used if DBUser and DBPassword are not specified);
- **VaultTLSCertFile**, **VaultTLSKeyFile** - SSL certificate and key file names; setting up these options is not mandatory, but highly recommended;
- **VaultPrefix** - custom prefix for the vault path or query, depending on the vault; if not specified, the most suitable default will be used.

Attention:

Zabbix server also uses the **Vault**, **VaultURL**, **VaultTLSCertFile**, **VaultTLSKeyFile**, and **VaultPrefix** configuration parameters for vault authentication when processing vault secret macros.

Zabbix server and Zabbix proxy read the vault-related configuration parameters from *zabbix_server.conf* and *zabbix_proxy.conf* files upon startup.

Example

1. In *zabbix_server.conf*, specify the following parameters:

```
Vault=CyberArk
VaultURL=https://127.0.0.1:1858
VaultDBPath=AppID=zabbix_server&Query=Safe=passwordSafe;Object=zabbix_server_database
VaultTLSCertFile=cert.pem
VaultTLSKeyFile=key.pem
VaultPrefix=/AIMWebService/api/Accounts?
```

2. Zabbix will send the following API request to the vault:

```
curl \
--header "Content-Type: application/json" \
--cert cert.pem \
--key key.pem \
https://127.0.0.1:1858/AIMWebService/api/Accounts?AppID=zabbix_server&Query=Safe=passwordSafe;Object=zabbix_server_database
```

3. The vault response will contain the keys "Content" and "UserName":

```
{
  "Content": <password>,
  "UserName": <username>,
  "Address": <address>,
  "Database": <Database>,
  "PasswordChangeInProgress": <PasswordChangeInProgress>
}
```

4. As a result, Zabbix will use the following credentials for database authentication:

- Username: <username>
- Password: <password>

Frontend

To obtain database credentials from the vault for Zabbix frontend, specify the following parameters during frontend **installation**.

1. At the *Configure DB Connection* step, set the *Store credentials in* parameter to "CyberArk Vault".

Configure DB connection

Welcome

Check of pre-requisites

Configure DB connection

Settings

Pre-installation summary

Install

Database port 0 - use default port

Database name

Store credentials in ☐ Plain text ☐ HashiCorp Vault ☒ CyberArk Vault

* Vault secret query string

Vault certificates ☒

SSL certificate file

SSL key file

Database TLS encryption *Connection will not be encrypted because it uses a socket file (on Unix) or shared memory (Windows).*

[Back](#)

[Next step](#)

2. Then, fill in the additional parameters:

| Parameter | Mandatory | Default value | Description |
|---------------------------|-----------|------------------------------|---|
| Vault API endpoint | yes | https://localhost:1858 | Specify the URL for connecting to the vault in the format <code>scheme://host:port</code> |
| Vault prefix | no | /AIMWebService/api/Accounts? | Provide a custom prefix for the vault path or query. If not specified, the default is used. |
| Vault secret query string | yes | | A query, which specifies from where database credentials should be retrieved. Example: <code>AppID=foo&Query=Safe=bar;Object=buzz</code> |
| Vault certificates | no | | After marking the checkbox, additional parameters will appear allowing to configure client authentication. While this parameter is optional, it is highly recommended to enable it for communication with the CyberArk Vault. |
| SSL certificate file | no | conf/certs/cyberark-cert.pem | Path to the SSL certificate file. The file must be in PEM format. If the certificate file also contains the private key, leave the SSL key file parameter empty. |
| SSL key file | no | conf/certs/cyberark-key.pem | Name of the SSL private key file used for client authentication. The file must be in PEM format. |

User macro values

To use CyberArk Vault for storing *Vault secret* user macro values, make sure that:

- Zabbix server is **configured** to work with CyberArk Vault;
- the *Vault provider* parameter in **Administration** → **General** → **Other** is set to "CyberArk Vault".

Storage of secrets

Vault provider ☐ HashiCorp Vault ☒ CyberArk Vault

Note:

Only Zabbix server requires access to *Vault secret* macro values from the vault. Other Zabbix components (proxy, frontend) do not need such access.

The macro value should contain a query (as `query:key`).

See [Vault secret macros](#) for detailed information on macro value processing by Zabbix.

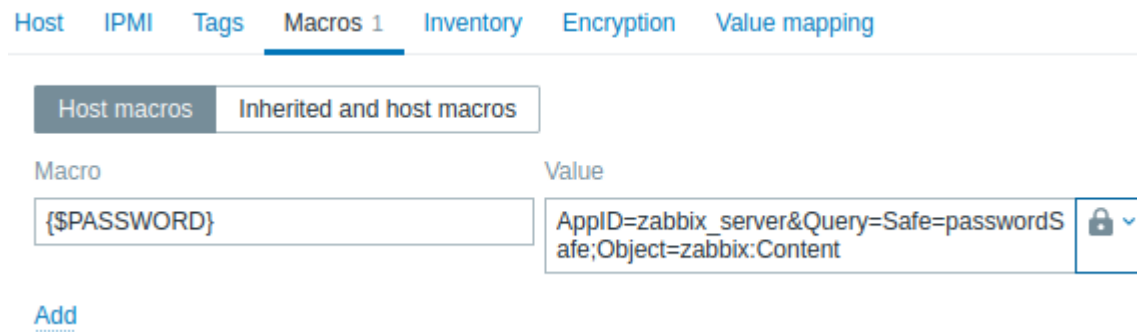

Query syntax

The colon symbol (":") is reserved for separating the query from the key.

If a query itself contains a forward slash or a colon, these symbols should be URL-encoded ("/" is encoded as "%2F", ":" is encoded as "%3A").

Example

1. In Zabbix, add a user macro {\$PASSWORD} of type *Vault secret* and with the value AppID=zabbix_server&Query=Safe=passwordSafe;Object=zabbix:Content

2. Zabbix will send the following API request to the vault:

```
curl \
--header "Content-Type: application/json" \
--cert cert.pem \
--key key.pem \
https://127.0.0.1:1858/AIMWebService/api/Accounts?AppID=zabbix_server&Query=Safe=passwordSafe;Object=zabbix:Content
```

3. The vault response will contain the key "Content":

```
{
  "Content": <password>,
  "UserName": <username>,
  "Address": <address>,
  "Database": <Database>,
  "PasswordChangeInProgress": <PasswordChangeInProgress>
}
```

4. As a result, Zabbix will resolve the macro {\$PASSWORD} to the value - <password>

Update existing configuration

To update an existing configuration for retrieving secrets from a CyberArk Vault:

1. Update the Zabbix server or proxy configuration file parameters as described in the [Database credentials](#) section.
2. Update the DB connection settings by reconfiguring Zabbix frontend and specifying the required parameters as described in the [Frontend](#) section. To reconfigure Zabbix frontend, open the frontend setup URL in the browser:
 - for Apache: `http://<server_ip_or_name>/zabbix/setup.php`
 - for Nginx: `http://<server_ip_or_name>/setup.php`

Alternatively, these parameters can be set in the [frontend configuration file](#) (`zabbix.conf.php`):

```
$DB['VAULT']           = 'CyberArk';
$DB['VAULT_URL']       = 'https://127.0.0.1:1858';
$DB['VAULT_DB_PATH']   = 'AppID=foo&Query=Safe=bar;Object=buzz';
$DB['VAULT_TOKEN']     = '';
$DB['VAULT_CERT_FILE'] = 'conf/certs/cyberark-cert.pem';
$DB['VAULT_KEY_FILE']  = 'conf/certs/cyberark-key.pem';
$DB['VAULT_PREFIX']    = '';
```

3. Configure user macros as described in the [User macro values](#) section, if necessary.

To update an existing configuration for retrieving secrets from a HashiCorp Vault, see [HashiCorp configuration](#).

2 HashiCorp configuration

Overview

This section explains how to configure Zabbix for retrieving secrets from HashiCorp Vault KV Secrets Engine - Version 2.

The vault should be deployed and configured as described in the official [HashiCorp documentation](#).

To learn about configuring TLS in Zabbix, see *Storage of secrets*.

Retrieving database credentials

To retrieve a secret with database credentials successfully, it is required to configure both:

- Zabbix server/proxy
- Zabbix frontend

Server/proxy

To configure Zabbix **server** or **proxy**, specify the following configuration parameters in the configuration file:

- `Vault` - which vault provider should be used;
- `VaultToken` - vault authentication token (see Zabbix server/proxy configuration file for details);
- `VaultURL` - vault server HTTP[S] URL;
- `VaultDBPath` - path to the vault secret containing database credentials (this option can only be used if `DBUser` and `DBPassword` are not specified); Zabbix server or proxy will retrieve the credentials by keys "password" and "username";
- `VaultPrefix` - custom prefix for the vault path or query, depending on the vault; if not specified, the most suitable default will be used.

Attention:

Zabbix server also uses the `Vault`, `VaultToken`, `VaultURL`, and `VaultPrefix` configuration parameters for vault authentication when processing vault secret macros.

Zabbix server and Zabbix proxy read the vault-related configuration parameters from `zabbix_server.conf` and `zabbix_proxy.conf` upon startup. Additionally, Zabbix server and Zabbix proxy will read the `VAULT_TOKEN` environment variable once during startup and will unset it so that it would not be available through forked scripts; it is an error if both `VaultToken` and `VAULT_TOKEN` parameters contain a value.

Example

1. In `zabbix_server.conf`, specify the following parameters:

```
Vault=HashiCorp
VaultToken=hvs.CAESIIG_PILmULFY0sEyWHxkZ2mF2a8VPKNLE8eHqd4autYGGH4KHGH2cy5aeTYONFNSaUp3ZnpWbDF1RUNjUkNTZEg
VaultURL=https://127.0.0.1:8200
VaultDBPath=database
VaultPrefix=/v1/secret/data/zabbix/
```

2. Run the following CLI commands to create the required secret in the vault:

```
#### Enable "secret/" mount point if not already enabled; note that "kv-v2" must be used.
vault secrets enable -path=secret/ kv-v2

#### Put new secrets with keys username and password under mount point "secret/" and path "zabbix/database"
vault kv put -mount=secret zabbix/database username=zabbix password=<password>

#### Test that secret is successfully added.
vault kv get secret/zabbix/database

#### Finally test with Curl; note that "data" need to be manually added after mount point and "/v1" before
curl --header "X-Vault-Token: <VaultToken>" https://127.0.0.1:8200/v1/secret/data/zabbix/database
```

3. As a result, Zabbix server will retrieve the following credentials for database authentication:

- Username: zabbix
- Password: <password>

Frontend

Zabbix frontend can be configured to retrieve database credentials from the vault either during frontend **installation** or by updating the frontend configuration file (`zabbix.conf.php`).

Attention:

If vault credentials have been changed since the previous frontend installation, rerun the frontend installation or update `zabbix.conf.php`. See also: [Updating existing configuration](#).

During **frontend installation** the configuration parameters must be specified at the *Configure DB Connection* step:

- Set the *Store credentials in* parameter to "HashiCorp Vault".
- Specify the connection parameters:

| Parameter | Mandatory | Default value | Description |
|-----------------------------------|-----------|------------------------|---|
| <i>Vault API endpoint</i> | yes | https://localhost:8200 | Specify the URL for connecting to the vault in the format <code>scheme://host:port</code> |
| <i>Vault prefix</i> | no | /v1/secret/data/ | Provide a custom prefix for the vault path or query. If not specified, the default is used. Example: <code>/v1/secret/data/zabbix/</code> |
| <i>Vault secret path</i> | no | | A path to the secret from where credentials for the database shall be retrieved by the keys "password" and "username". Example: <code>database</code> |
| <i>Vault authentication token</i> | no | | Provide an authentication token for read-only access to the secret path. See HashiCorp documentation for information about creating tokens and vault policies. |

Retrieving user macro values

To use HashiCorp Vault for storing *Vault secret* user macro values, make sure that:

- Zabbix server is **configured** to work with HashiCorp Vault;
- the *Vault provider* parameter in **Administration** → **General** → **Other** is set to "HashiCorp Vault" (default).

Storage of secrets

Vault provider HashiCorp Vault CyberArk Vault

Note:

Only Zabbix server requires access to *Vault secret* macro values from the vault. Other Zabbix components (proxy, frontend) do not need such access.

The macro value should contain a reference path (as `path:key`, for example, `macros:password`). The authentication token specified during Zabbix server configuration (by the `VaultToken` parameter) must provide read-only access to this path.

See [Vault secret macros](#) for detailed information on macro value processing by Zabbix.

Path syntax

The symbols forward slash ("/") and colon (":") are reserved.

A forward slash can only be used to separate a mount point from a path (e.g., `secret/zabbix` where the mount point is "secret" and the path is "zabbix"). In the case of Vault macros, a colon can only be used to separate a path/query from a key.

It is possible to URL-encode the forward slash and colon symbols if there is a need to create a mount point with the name that is separated by a forward slash (e.g., `foo/bar/zabbix`, where the mount point is "foo/bar" and the path is "zabbix", can be encoded as "foo%2Fbar/zabbix") and if a mount point name or path need to contain a colon.

Example

1. In Zabbix, add a user macro `{PASSWORD}` of type "Vault secret" and with the value `macros:password`

| Host macros | Inherited and host macros |
|---|---|
| Macro | Value |
| <input data-bbox="151 786 743 842" type="text" value="{PASSWORD}"/> | <input data-bbox="759 786 1377 842" type="text" value="macros:password"/>  |
| Add | |

2. Run the following CLI commands to create required secret in the vault:

```
#### Enable "secret/" mount point if not already enabled; note that "kv-v2" must be used.
vault secrets enable -path=secret/ kv-v2
```

```
#### Put new secret with key "password" under mount point "secret/" and path "zabbix/macros".
vault kv put -mount=secret zabbix/macros password=<password>
```

```
#### Test that secret is successfully added.
vault kv get secret/zabbix/macros
```

```
#### Finally test with Curl; note that "data" need to be manually added after mount point and "/v1" before
curl --header "X-Vault-Token: <VaultToken>" https://127.0.0.1:8200/v1/secret/data/zabbix/macros
```

3. As a result, Zabbix will resolve the macro `{PASSWORD}` to the value: `<password>`

Updating existing configuration

To update an existing configuration for retrieving secrets from a HashiCorp Vault:

1. Update the Zabbix server or proxy configuration file parameters as described in the [Database credentials](#) section.
2. Update the DB connection settings by reconfiguring Zabbix frontend and specifying the required parameters as described in the [Frontend](#) section. To reconfigure Zabbix frontend, open the frontend setup URL in the browser:
 - for Apache: `http://<server_ip_or_name>/zabbix/setup.php`
 - for Nginx: `http://<server_ip_or_name>/setup.php`

Alternatively, these parameters can be set in the [frontend configuration file](#) (`zabbix.conf.php`):

```
$DB['VAULT']           = 'HashiCorp';
$DB['VAULT_URL']       = 'https://localhost:8200';
$DB['VAULT_DB_PATH']   = 'database';
$DB['VAULT_TOKEN']     = '<mytoken>';
$DB['VAULT_CERT_FILE'] = '';
$DB['VAULT_KEY_FILE']  = '';
$DB['VAULT_PREFIX']    = '/v1/secret/data/zabbix/';
```

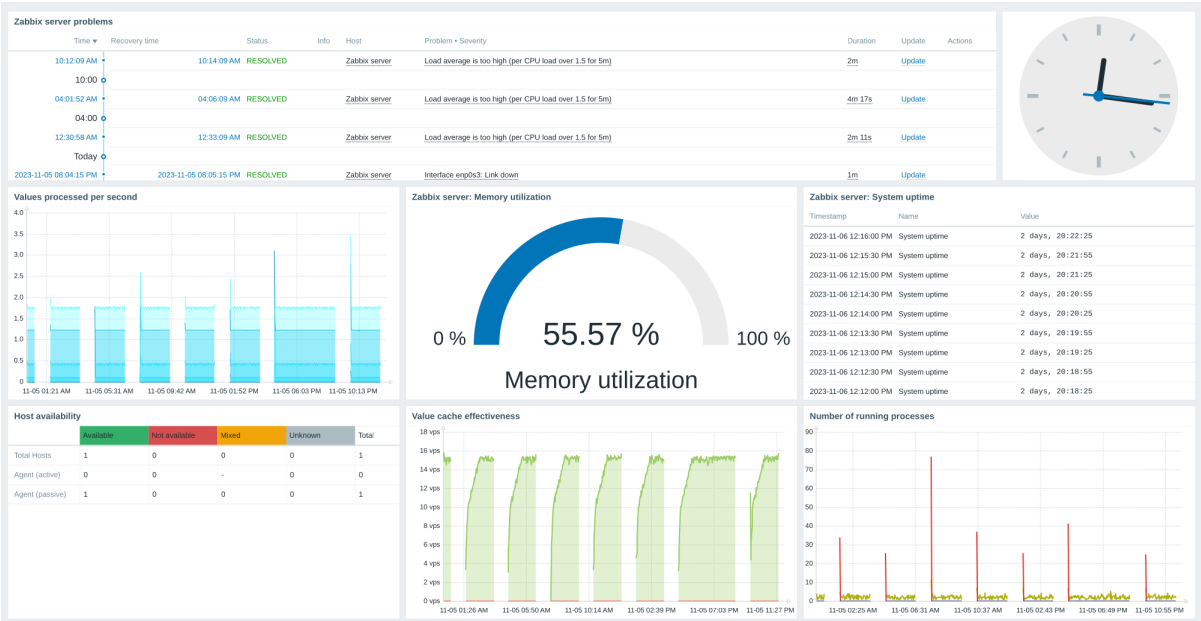

3. Configure user macros as described in the [User macro values](#) section, if necessary.

To update an existing configuration for retrieving secrets from a CyberArk Vault, see [CyberArk configuration](#).

14 Scheduled reports

Overview

With the *Scheduled reports* feature, you can set up a PDF version of a given dashboard to be sent to specified recipients at recurring intervals.

Pre-requisites:

- Zabbix web service must be installed and configured correctly to enable scheduled report generation - see [Setting up scheduled reports](#) for instructions.
- A user must have a **user role** of type *Admin* or *Super admin* with the following permissions:
 - *Scheduled reports* in the *Access to UI elements* block (to view reports)
 - *Manage scheduled reports* in the *Access to actions* block (to create/edit reports)

To create a scheduled report in Zabbix frontend, do the following:

- Go to: *Reports* → *Scheduled reports*
- Click *Create report* in the upper right corner of the screen
- Enter parameters of the report in the form

You can also create a report by opening an existing one, clicking the *Clone* button, and then saving it under a different name.

Configuration

The *Scheduled reports* tab contains general report attributes.

All mandatory input fields are marked with a red asterisk.

497

| Parameter | Description |
|----------------------|---|
| <i>Start date</i> | Date when regular report generation should be started. |
| <i>End date</i> | Date when regular report generation should be stopped. |
| <i>Subject</i> | Subject of the report email. Supported macros: {TIME}, {TIMESTAMP}. |
| <i>Message</i> | Body of the report email. Supported macros: {TIME}, {TIMESTAMP}. |
| <i>Subscriptions</i> | <p>List of report recipients. By default, includes only the report owner. Any Zabbix user with configured email media may be specified as a report recipient.</p> <p>Click <i>Add user</i> or <i>Add user group</i> to add more recipients.</p> <p>Click the username to edit settings:</p> <p><i>Generate report by</i> - whether the report data should be generated based on the dashboard permissions of the current user or the recipient.</p> <p><i>Status</i> - select "Include" to send the report to the user or "Exclude" to prevent sending the report to this user. At least one user must have the "Include" status. The "Exclude" status can be used to exclude specific users from a user group that is included.</p> <p>Note that users with insufficient permissions (that is, users with a role based on the <i>Admin</i> user type who are not members of the same user group as the recipient or report owner) will see "Inaccessible user" or "Inaccessible user group" instead of the actual names in the fields <i>Recipient</i> and <i>Generate report by</i>; the fields <i>Status</i> and <i>Action</i> will be displayed as read-only.</p> |
| <i>Enabled</i> | Report status. Clearing this checkbox will disable the report. |
| <i>Description</i> | An optional description of the report. This description is for internal use and will not be sent to report recipients. |

Form buttons

Buttons at the bottom of the form allow to perform several operations.

| | |
|---------------|--|
| Add | Add a report. This button is only available for new reports. |
| Update | Update the properties of a report. |
| Clone | Create another report based on the properties of the current report. |
| Test | Test if report configuration is correct by sending a report to the current user. |
| Delete | Delete the report. |
| Cancel | Cancel the editing of report properties. |

Testing

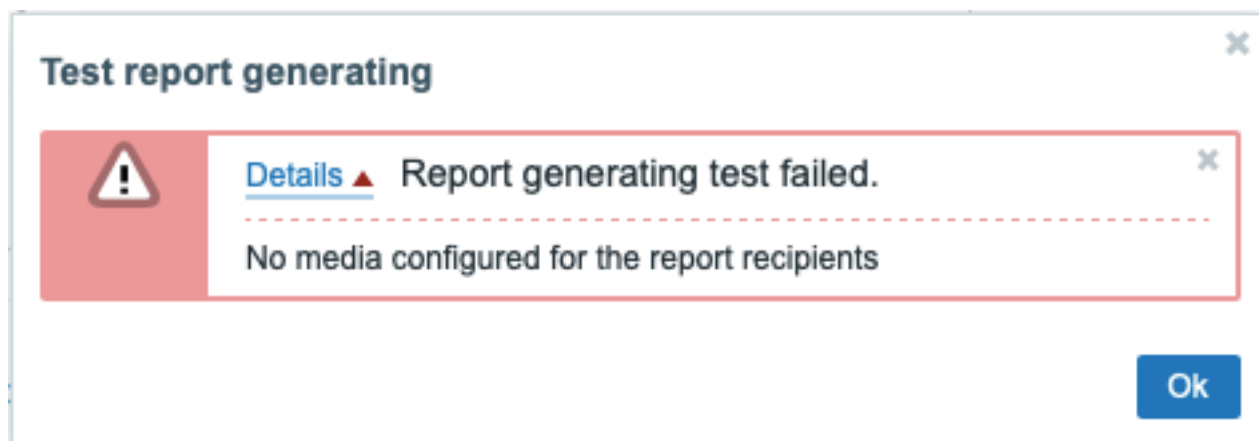

To test a report, click the *Test* button at the bottom of the report configuration form.

Note:

The *Test* button is not available if the report configuration form has been opened from the dashboard **action menu**.

If the configuration is correct, the test report is sent immediately to the current user. For test reports, subscribers and *Generate report by* user settings are ignored.

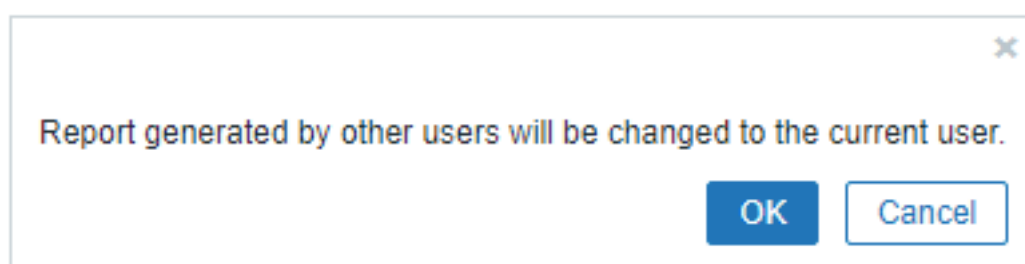

If the configuration is incorrect, an error message is displayed describing the possible cause.

Updating a report

To update an existing report, click the report name, make the required configuration changes, and then click the *Update* button.

If an existing report is updated by another user and this user changes the Dashboard, upon clicking the *Update* button, a warning message "Report generated by other users will be changed to the current user" will be displayed.

Clicking *OK* at this step will lead to the following changes:

- *Generate report by* settings will be updated to display the user who edited the report last (unless *Generate report by* is set to the recipient).
- Users that have been displayed as "Inaccessible user" or "Inaccessible user group" will be deleted from the list of report subscribers.

Clicking *Cancel* will close the configuration form and cancel the report update.

Cloning a report

To quickly clone an existing report, click the *Clone* button at the bottom of an existing report configuration form. When cloning a report created by another user, the current user becomes the owner of the new report.

Report settings will be copied to the new report configuration form with respect to user permissions:

- If the user who clones a report has no permissions to a dashboard, the *Dashboard* field will be cleared.
- If the user who clones a report has no permissions to some users or user groups in the *Subscriptions* list, inaccessible recipients will not be cloned.
- *Generate report by* settings will be updated to display the current user (unless *Generate report by* is set to the recipient).

Change the required settings and the report name, then click *Add*.

15 Data export

Overview

Zabbix supports data export in real-time in two ways:

- **export to files**
- **streaming to external systems**

The following entities can be exported:

- trigger events
- item values
- trends (export to files only)

1 Export to files

Overview

It is possible to configure real-time exporting of trigger events, item values and trends in a newline-delimited JSON format.

Exporting is done into files, where each line of the export file is a JSON object. Value mappings are not applied.

In case of errors (data cannot be written to the export file or the export file cannot be renamed or a new one cannot be created after renaming it), the data item is dropped and never written to the export file. It is written only in the Zabbix database. Writing data to the export file is resumed when the writing problem is resolved.

For precise details on what information is exported, see the [export protocol](#) page.

Note that host/item can have no metadata (host groups, host name, item name) if the host/item was removed after the data was received, but before server exported data.

Configuration

Real-time export of trigger events, item values and trends is configured by specifying a directory for the export files - see the [ExportDir](#) parameter in server configuration.

Two other parameters are available:

- `ExportFileSize` may be used to set the maximum allowed size of an individual export file. When a process needs to write to a file it checks the size of the file first. If it exceeds the configured size limit, the file is renamed by appending `.old` to its name and a new file with the original name is created.

Attention:

A file will be created per each process that will write data (i.e. approximately 4-30 files). As the default size per export file is 1G, keeping large export files may drain the disk space fast.

- `ExportType` allows to specify which entity types (events, history, trends) will be exported.

2 Streaming to external systems

Overview

It is possible to stream item values and events from Zabbix to external systems over HTTP (see [protocol details](#)).

The tag filter can be used to stream subsets of item values or events.

Two Zabbix server processes are responsible for data streaming: `connector manager` and `connector worker`. A Zabbix internal item `zabbix[connector_queue]` allows to monitor the count of values enqueued in the connector queue.

Configuration

The following steps are required to configure data streaming to an external system:

1. Have a remote system set up for receiving data from Zabbix. For this purpose, the following tools are available:
 - An example of a simple [receiver](#) that logs the received information in `events.ndjson` and `history.ndjson` files.
 - [Kafka connector for Zabbix server](#) - a lightweight server written in Go, designed to forward item values and events from a Zabbix server to a Kafka broker.
2. Set the required number of connector workers in Zabbix by adjusting the `StartConnectors` parameter in `zabbix_server.conf`. The number of connector workers should match (or exceed if concurrent sessions are more than 1) the configured connector count in Zabbix frontend. Then, restart Zabbix server.
3. Configure a new connector in Zabbix frontend (*Administration* → *General* → *Connectors*) and reload the server cache with the `zabbix_server -R config_cache_reload` command.

Mandatory fields are marked by an asterisk.

| Parameter | Description |
|------------------|---|
| <i>Name</i> | Enter the connector name. |
| <i>Data type</i> | Select the data type to stream: Item values - stream item values from Zabbix to external systems; Events - stream events from Zabbix to external systems. |
| <i>URL</i> | Enter the receiver URL. User macros are supported. |

| Parameter | Description |
|--------------------------------|--|
| <i>Tag filter</i> | <p>Export only item values or events matching the tag filter. If not set, then export everything. It is possible to include as well as exclude specific tags and tag values. Several conditions can be set. Tag name matching is always case-sensitive.</p> <p>There are several operators available for each condition: Exists - include the specified tag names; Equals - include the specified tag names and values (case-sensitive); Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive); Does not exist - exclude the specified tag names; Does not equal - exclude the specified tag names and values (case-sensitive); Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).</p> <p>There are two calculation types for conditions: And/Or - all conditions must be met, conditions having the same tag name will be grouped by the Or condition; Or - enough if one condition is met.</p> |
| <i>Type of information</i> | <p>Select the type of information (numeric (unsigned), numeric (float), character, etc.), by which to filter the item values that the connector should stream.</p> <p>This field is available if <i>Data type</i> is set to "Item values".</p> |
| <i>HTTP authentication</i> | <p>Select the authentication option: None - no authentication used; Basic - basic authentication is used; NTLM - NTLM (Windows NT LAN Manager) authentication is used; Kerberos - Kerberos authentication is used (see also: Configuring Kerberos with Zabbix); Digest - Digest authentication is used; Bearer - Bearer authentication is used.</p> |
| <i>Username</i> | <p>Enter the user name (up to 255 characters). User macros are supported.</p> |
| <i>Password</i> | <p>Enter the user password (up to 255 characters). User macros are supported.</p> |
| <i>Bearer token</i> | <p>Enter the Bearer token. User macros are supported.</p> |
| <i>Advanced configuration</i> | <p>Click the <i>Advanced configuration</i> label to display advanced configuration options (see below).</p> |
| <i>Max records per message</i> | <p>Specify the maximum number of values or events that can be streamed within one message.</p> |
| <i>Concurrent sessions</i> | <p>Select the number of sender processes to run for this connector. Up to 100 sessions can be specified; the default value is "1".</p> |
| <i>Attempts</i> | <p>Number of attempts for streaming data. Up to 5 attempts can be specified; the default value is "1".</p> |
| <i>Attempt interval</i> | <p>Specify how long the connector should wait after an unsuccessful attempt to stream data. Up to 10s can be specified; the default value is "5s".</p> <p>This field is available if <i>Attempts</i> is set to "2" or more.</p> <p>Unsuccessful attempts are those where establishing a connection has failed, or where the HTTP response code is not 200, 201, 202, 203, 204. Retries are triggered in case of communication errors or when the HTTP response code is not 200, 201, 202, 203, 204, 400, 401, 403, 404, 405, 415, 422. Redirects are followed, so 302 -> 200 is a positive response; whereas 302 -> 503 will trigger a retry.</p> |
| <i>Timeout</i> | <p>Specify the message timeout (1-60 seconds, default - 5 seconds).</p> <p>Time suffixes are supported, e.g., 30s, 1m. User macros are supported.</p> |

| Parameter | Description |
|-----------------------------|---|
| <i>HTTP proxy</i> | <p>You can specify an HTTP proxy to use in the following format: <code>[protocol://] [username[:password]@]proxy.example.com[:port]</code> User macros are supported.</p> <p>The optional <code>protocol://</code> prefix may be used to specify alternative proxy protocols (the protocol prefix support was added in cURL 7.21.7). With no protocol specified, the proxy will be treated as an HTTP proxy. By default, 1080 port will be used.</p> <p>If <i>HTTP proxy</i> is specified, the proxy will overwrite proxy related environment variables like <code>http_proxy</code>, <code>HTTPS_PROXY</code>. If not specified, the proxy will not overwrite proxy-related environment variables. The entered value is passed on as is, no sanity checking takes place. You may also enter a SOCKS proxy address. If you specify the wrong protocol, the connection will fail and the item will become unsupported.</p> |
| <i>SSL verify peer</i> | <p>Note that only simple authentication is supported with HTTP proxy.</p> <p>Mark the checkbox to verify the SSL certificate of the web server.</p> <p>The server certificate will be automatically taken from system-wide certificate authority (CA) location. You can override the location of CA files using Zabbix server or proxy configuration parameter <code>SSLCALocation</code>.</p> |
| <i>SSL verify host</i> | <p>Mark the checkbox to verify that the <i>Common Name</i> field or the <i>Subject Alternate Name</i> field of the web server certificate matches.</p> <p>This sets the <code>CURLOPT_SSL_VERIFYHOST</code> cURL option.</p> |
| <i>SSL certificate file</i> | <p>Name of the SSL certificate file used for client authentication. The certificate file must be in PEM¹ format. User macros are supported.</p> <p>If the certificate file also contains the private key, leave the <i>SSL key file</i> field empty. If the key is encrypted, specify the password in the <i>SSL key password</i> field. The directory containing this file is specified by Zabbix server or proxy configuration parameter <code>SSLCertLocation</code>.</p> |
| <i>SSL key file</i> | <p>Name of the SSL private key file used for client authentication. The private key file must be in PEM¹ format. User macros are supported.</p> <p>The directory containing this file is specified by Zabbix server or proxy configuration parameter <code>SSLKeyLocation</code>.</p> |
| <i>SSL key password</i> | SSL private key file password. User macros are supported. |
| <i>Description</i> | Enter the connector description. |
| <i>Enabled</i> | Mark the checkbox to enable the connector. |

Protocol

Communication between the server and the receiver is done over HTTP using REST API, NDJSON, "Content-Type: application/x-ndjson".

For more details, see [Newline-delimited JSON export protocol](#).

Server request

Example of streaming item values:

```
POST /v1/history HTTP/1.1
Host: localhost:8080
Accept: */*
Accept-Encoding: deflate, gzip, br, zstd
Content-Length: 628
Content-Type: application/x-ndjson
```

```
{"host":{"host":"Zabbix server","name":"Zabbix server"},"groups":["Zabbix servers"],"item_tags":[{"tag":"f
{"host":{"host":"Zabbix server","name":"Zabbix server"},"groups":["Zabbix servers"],"item_tags":[{"tag":"f
{"host":{"host":"Zabbix server","name":"Zabbix server"},"groups":["Zabbix servers"],"item_tags":[{"tag":"b
```

Example of streaming events:

```
POST /v1/events HTTP/1.1
Host: localhost:8080
Accept: */*
Accept-Encoding: deflate, gzip, br, zstd
Content-Length: 333
```

```
Content-Type: application/x-ndjson
```

```
{"clock":1673454303,"ns":800155804,"value":1,"eventid":5,"name":"trigger for foo being 0","severity":0,"hostid":1}
{"clock":1673454303,"ns":832290669,"value":0,"eventid":6,"p_eventid":5}
```

Receiver response

The response consists of the HTTP response status code and the JSON payload. The HTTP response status code must be "200", "201", "202", "203", or "204" for requests that were handled successfully, other for failed requests.

Example of success:

```
localhost:8080/v1/history": HTTP/1.1 200 OK
Date: Wed, 11 Jan 2023 16:40:30 GMT
Content-Length: 0
```

Example with errors:

```
localhost:8080/v1/history": HTTP/1.1 422 Unprocessable Entity
Content-Type: application/json
Date: Wed, 11 Jan 2023 17:07:36 GMT
Content-Length: 55

{"error":"invalid character '{' after top-level value"}
```

3 SNMP gateway

Overview

Zabbix SNMP gateway is an AgentX-extension for snmpd supporting both SNMP polling and trapping.

With Zabbix SNMP gateway it is possible to use the SNMP protocol to retrieve:

- trigger data;
- problem trigger data;
- host group status (count of triggers by trigger status per group)

The data is retrieved by the OID, which is a combination of a common base and a specific suffix. The common **base** is set in the configuration file of SNMP gateway, for example:

- BaseOID=1.3.6.1.4.1.3043.7.55 - for any trigger data;
- ProblemBaseOID=1.3.6.1.4.1.3047.7.55 - for problem trigger data;
- BaseOID=1.3.6.1.4.1.3046.7.55 - for host group status.

The OID **suffix** is set in the configuration on host triggers as a **tag** (for example, OIDSuffix:3) in the frontend.

In this case all information for the trigger will be available under OID=1.3.6.1.4.1.3043.7.55.X.3. "X" here will be the number of trigger data fields (i.e. 1 - suffix, 2 - ID, 3 - expression, 4 - description, etc.).

For a more detailed description and the configuration file example, see the [SNMP gateway readme file](#).

Installation and setup

See the [readme](#) file of SNMP gateway for instructions on:

- installing and configuring snmpd;
- enabling AgentX support;
- configuring Zabbix SNMP gateway;
- configuring SNMP traps for trigger state changes.

Retrieving data

With everything set up properly, you may use snmpwalk and snmpget commands to retrieve data:

```
[user@localhost ~]# snmpget -v2c -c public 127.0.0.1 1.3.6.1.4.1.3043.7.55.2.3
SNMPv2-SMI::enterprises.3043.7.55.2.3 = INTEGER: 15247

[user@localhost ~]# snmpwalk -v2c -c public 127.0.0.1 1.3.6.1.4.1.3043.7.55
SNMPv2-SMI::enterprises.3043.7.55.1.1 = INTEGER: 1
SNMPv2-SMI::enterprises.3043.7.55.1.3 = INTEGER: 3
SNMPv2-SMI::enterprises.3043.7.55.1.4 = INTEGER: 4
SNMPv2-SMI::enterprises.3043.7.55.1.5 = INTEGER: 5
```

```
SNMPv2-SMI::enterprises.3043.7.55.1.6 = INTEGER: 6
SNMPv2-SMI::enterprises.3043.7.55.1.10 = INTEGER: 10
SNMPv2-SMI::enterprises.3043.7.55.2.1 = INTEGER: 15367
SNMPv2-SMI::enterprises.3043.7.55.2.3 = INTEGER: 15247
SNMPv2-SMI::enterprises.3043.7.55.2.4 = INTEGER: 15365
SNMPv2-SMI::enterprises.3043.7.55.2.5 = INTEGER: 15366
SNMPv2-SMI::enterprises.3043.7.55.2.6 = INTEGER: 13493
SNMPv2-SMI::enterprises.3043.7.55.2.10 = INTEGER: 13503
...
```

Filtering options

You may limit the problem trigger information in SNMP gateway configuration:

- by severity (by default ProblemMinSeverity=-1)
- by hiding acknowledged problems (by default ProblemHideAck=false)

You may limit the problem count per host group in SNMP gateway configuration:

- by unknown state triggers (by default CountUnknown=false)
- by triggers with acknowledged/unacknowledged/all problems (by default CountAcknowledgeStatus=all)

8 Service monitoring

Overview Service monitoring is a business-level monitoring that can be used to get an overview of the entire IT infrastructure service tree, identify weak places of the infrastructure, calculate SLA of various IT services, and check out other information at a higher level. Service monitoring focuses on the overall availability of a service instead of low-level details, such as the lack of disk space, high processor load, etc. Service monitoring also provides functionality to find the root cause of a problem if a service is not performing as expected.

Service monitoring allows to create a hierarchy representation of monitored data.

A very simple service structure may look like:

```
Service
|
|-Workstations
| |
| |-Workstation1
| |
| |-Workstation2
|
|-Servers
```

Each node of the structure has attribute status. The status is calculated and propagated to upper levels according to the selected algorithm. The status of individual nodes is affected by the status of the mapped problems. Problem mapping is accomplished with **tagging**.

Zabbix can send notifications or automatically execute a script on the Zabbix server in case service status change is detected. It is possible to define flexible rules whether a parent service should go into a 'Problem state' based on the statuses of child services. Services problem data can then be used to calculate SLA and send SLA reports based on the flexible set of conditions.

Service monitoring is configured in the Services menu, which consists of the following sections:

- **Services**

Services section allows to build a hierarchy of your monitored infrastructure by adding parent services, and then - child services to the parent services.

In addition to configuring service tree, this section provides an overview of the whole infrastructure and allows to quickly identify the problems that led to a service status change.

- **SLA**

In this section you can define service level agreements and set service level objectives for specific services.

- **SLA report**

In this section you can view SLA reports.

Service actions

You may also configure service **actions**.

Service actions are optional and allow to:

- send a notification that a service is down
- execute a remote command on a Zabbix server upon a service status change
- send a recovery notification when a service is up again.

See also:

- SLA monitoring configuration **example**
- Notes about **upgrading services** from Zabbix versions below 6.0

1 Service tree

The service tree is configured in the *Services* -> *Services* menu section. In the upper right corner, switch from **View** to the Edit mode.

| <i>N (W)</i> | If several conditions are specified and the situation matches more than one condition, the highest severity will be set. |
| <i>Status</i> | Set the value of N or W (1-100000), or N% (1-100) in the condition. |
| Status propagation rule | <p>Select the value of <i>Status</i> in the condition: <i>OK</i> (default), <i>Not classified</i>, <i>Information</i>, <i>Warning</i>, <i>Average</i>, <i>High</i> or <i>Disaster</i>.</p> <p>Rule for propagating the service status to the parent service:</p> <p>As is - the status is propagated without change</p> <p>Increase by - you may increase the propagated status by 1 to 5 severities</p> <p>Decrease by - you may decrease the propagated status by 1 to 5 severities</p> <p>Ignore this service - the status is not propagated to the parent service at all</p> <p>Fixed status - the status is propagated statically, i.e. as always the same</p> |
| Weight | Weight of the service (integer in the range from 0 (default) to 1000000). |

Note:

Additional status calculation rules can only be used to increase severity level over the level calculated according to the main *Status calculation rule* parameter. If according to additional rules the status should be *Warning*, but according to the *Status calculation rule* the status is *Disaster* - the service will have status *Disaster*.

The **Tags** tab contains **service-level tags**. Service-level tags are used to identify a service. Tags of this type are not used to map problems to the service (for that, use **Problem tags** from the first tab).

The **Child services** tab allows to specify dependant services. Click on *Add* to add a service from the list of existing services. If you want to add a new child service, save this service first, then click on a plus icon next to the service that you have just created.

Tags There are two different types of tags in services:

- Service tags
- Problem tags

Service tags

Service tags are used to match services with **service actions** and **SLAs**. These tags are specified at the *Tags* service configuration tab. For mapping SLAs, *OR* logic is used: a service will be mapped to an SLA if it has at least one matching tag. In service actions, mapping rules are configurable and can use either *AND*, *OR*, or *AND/OR* logic.

| Service | Tags 1 | Child services 2 | | | | | | |
|---------|--|------------------|------|-------|--|--------|--------|--|
| | <table border="1"> <thead> <tr> <th>Tags</th> <th>Name</th> <th>Value</th> </tr> </thead> <tbody> <tr> <td></td> <td>sla-id</td> <td>424084</td> </tr> </tbody> </table> | Tags | Name | Value | | sla-id | 424084 | |
| Tags | Name | Value | | | | | | |
| | sla-id | 424084 | | | | | | |

Problem tags

Problem tags are used to match problems and services. These tags are specified at the primary service configuration tab.

Only child services of the lowest hierarchy level may have problem tags defined and be directly correlated to problems. If problem tags match, the service status will change to the same status as the problem has. In case of several problems, a service will have the status of the most severe one. Status of a parent service is then calculated based on child services statuses according to Status calculation rules.

If several tags are specified, *AND* logic is used: a problem must have all tags specified in the service configuration to be mapped to the service.

| Problem tags | Name | Operation | Value |
|--------------|--------|-----------|--------------|
| | scope | Equals | availability |
| | target | Equals | mysql |

Note:

A problem in Zabbix inherits tags from the whole chain of templates, hosts, items, web scenarios, and triggers. Any of these tags can be used for matching problems to services.

Example:

Problem *Web camera 3 is down* has tags `type:video-surveillance`, `floor:1` and `name:webcam-3` and status *Warning*

The service **Web camera 3** has the only problem tag specified: `name:webcam-3`

| Problem tags | Name | Operation | Value |
|--------------|------|-----------|----------|
| | name | Equals | webcam-3 |

Service status will change from *OK* to *Warning* when this problem is detected.

If the service **Web camera 3** had problem tags `name:webcam-3` and `floor:2`, its status would not be changed, when the problem is detected, because the conditions are only partially met.

Note:

The buttons described below are visible only when *Services* section is in the Edit mode.

Modifying existing services

To edit an existing service, press the pencil icon next to the service.

To clone an existing service, press the pencil icon to open its configuration and then press Clone button. When a service is cloned, its parent links are preserved, while the child links are not.

To delete a service, press on the x icon next to it. When you delete a parent service, its child services will not be deleted and will move one level higher in the service tree (1st level children will get the same level as the deleted parent service).

Two buttons below the list of services offer some mass-editing options:

- *Mass update* - mass update service properties
- *Delete* - delete the services

To use these options, mark the checkboxes before the respective services, then click on the required button.

2 SLA

Overview Once the *services* are created, you can start monitoring whether their performance is on track with service level agreement (SLA).

Services->SLA menu section allows to configure SLAs for various services. An SLA in Zabbix defines service level objective (SLO), expected uptime schedule and planned downtimes.

SLAs and services are matched by **service tags**. The same SLA may be applied to multiple services - performance will be measured for each matching service separately. A single service may have multiple SLAs assigned - data for each of the SLAs will be displayed separately.

In SLA reports Zabbix provides Service level indicator (SLI) data, which measures real service availability. Whether a service meets the SLA targets is determined by comparing SLO (expected availability in %) with SLI (real-life availability in %).

Configuration To create a new SLA, click on the *Create SLA* button.

The **SLA** tab allows to specify general SLA parameters.

Add

Cancel

Click on *Add* to configure excluded downtimes, then enter the period name, start date and duration.

SLA reports How a service performs compared to an SLA is visible in the **SLA report**. SLA reports can be viewed:

- from the *SLA* section by clicking on the SLA report hyperlink;
- from the *Services* section by clicking on the SLA name in the info tab;
- in the Dashboard **widget SLA report**.

Once an SLA is configured, the *Info* tab in the services section will also display some information about service performance.

3 Setup example

Overview This section describes a simple setup for monitoring Zabbix high availability cluster as a service.

Pre-requisites Prior to configuring service monitoring, you need to have the hosts configured:

- *HA node 1* with at least one trigger and a tag (preferably set on a trigger level) `component:ha-node-1`
- *HA node 2* with at least one trigger and a tag (preferably set on a trigger level) `component:ha-node-2`

Service tree The next step is to build the service tree. In this example, the infrastructure is very basic and consists of three services: *Zabbix cluster* (parent) and two child services *Zabbix server node 1* and *Zabbix server node 2*.

```

Zabbix cluster
|
|- Zabbix server node 1
|- Zabbix server node 2

```

At the Services page, turn on *Edit* mode and press Create service:

Create service

View

Edit

In the service configuration window, enter name *Zabbix cluster* and click on the *Advanced configuration* label to display advanced configuration options.

Zabbix cluster will have two child services - one for each of the HA nodes. If both HA nodes have problems of at least *Warning* status, parent service status should be set to *Disaster*. To achieve this, additional rule should be configured as:

- Set status to: Disaster
- Condition: If at least N child services have Status status or above
- N: 2
- Status: Warning

Switch to the *Tags* tab and add a tag `application:zabbix-server`. This tag will be used later for service actions and SLA reports.

Service Tags 1 Child services

Tags

| Name | Value |
|-------------|---------------|
| application | zabbix-server |

Save the new service.

To add a child service, press on the plus icon next to the Zabbix cluster service (the icon is visible only in *Edit* mode).

| <input type="checkbox"/> Name | Status | Root cause | Created at | Tags | |
|---|--------|------------|------------|----------------------------|--|
| <input type="checkbox"/> Zabbix cluster | OK | | 2024-10-01 | application: zabbix-ser... | <div><div></div><div></div><div></div></div> |

Displaying 1 of 1 found

In the service configuration window, enter name *Zabbix server node 1*. Note that the Parent services parameter is already pre-filled with *Zabbix cluster*.

Availability of this service is affected by problems on the host *HA node 1*, marked with `component:HA node 1 problem` tag. In the Problem tags parameter, enter:

- Name: component
- Operation: Equals
- Value: ha-node-1

Switch to the *Tags* tab and add a service tag: `zabbix-server:node-1`. This tag will be used later for service actions and SLA reports.

Service Tags 1 Child services

Tags

| Name | Value |
|---------------|--------|
| zabbix-server | node-1 |

Save the new service.

Create another child service of Zabbix cluster with name "Zabbix server node 2".

Set the Problem tags as:

- Name: component
- Operation: Equals
- Value: ha-node-2

Switch to the *Tags* tab and add a service tag: `zabbix-server:node-2`.

Save the new service.

SLA In this example, expected Zabbix cluster performance is 100% excluding semi-annual one hour maintenance period.

First, you need to add a new service level agreement.

Go to the *Services->SLA* menu section and press Create SLA. Enter name *Zabbix cluster performance* and set the SLO to 100%.

The service Zabbix cluster has a service tag `application:zabbix-server`. To use this SLA for measuring performance of Zabbix cluster, in the *Service tags* parameter, specify:

- Name: application
- Operation: Equals
- Value: zabbix-server

9 Web monitoring

Overview With Zabbix you can check several availability aspects of web sites.

Attention:

To perform web monitoring Zabbix server must be initially **configured** with cURL (libcurl) support.

To activate web monitoring you need to define web scenarios. A web scenario consists of one or several HTTP requests or "steps". The steps are periodically executed by Zabbix server in a pre-defined order. If a host is monitored by proxy, the steps are executed by the proxy.

Web scenarios are attached to hosts/templates in the same way as items, triggers, etc. That means that web scenarios can also be created on a template level and then applied to multiple hosts in one move.

The following information is collected in any web scenario:

- average download speed per second for all steps of whole scenario
- number of the step that failed
- last error message

The following information is collected in any web scenario step:

- download speed per second
- response time

- response code

For more details, see [web monitoring items](#).

Data collected from executing web scenarios is kept in the database. The data is automatically used for graphs, triggers and notifications.

Zabbix can also check if a retrieved HTML page contains a pre-defined string. It can execute a simulated login and follow a path of simulated mouse clicks on the page.

Zabbix web monitoring supports both HTTP and HTTPS. When running a web scenario, Zabbix will optionally follow redirects (see option *Follow redirects* below). Maximum number of redirects is hard-coded to 10 (using cURL option [CURLOPT_MAXREDIRS](#)). All cookies are preserved during the execution of a single scenario.

Configuring a web scenario To configure a web scenario:

- Go to: *Data collection* → *Hosts* (or *Templates*)
- Click on *Web* in the row of the host/template
- Click on *Create web scenario* to the right (or on the scenario name to edit an existing scenario)
- Enter parameters of the scenario in the form

The **Scenario** tab allows you to configure the general parameters of a web scenario.

Scenario parameters:

| Parameter | Description |
|------------------------|---|
| <i>Name</i> | <p>Unique scenario name.</p> <p>User macros are supported. <i>Note</i> that if user macros are used, these macros will be left unresolved in web monitoring item names.</p> |
| <i>Update interval</i> | <p>How often the scenario will be executed.</p> <p>Time suffixes are supported, e.g. 30s, 1m, 2h, 1d.</p> <p>User macros are supported. <i>Note</i> that if a user macro is used and its value is changed (e.g. 5m → 30s), the next check will be executed according to the previous value (farther in the future with the example values).</p> <p>New web scenarios will be checked within 60 seconds of their creation.</p> |
| <i>Attempts</i> | <p>The number of attempts for executing web scenario steps. In case of network problems (timeout, no connectivity, etc) Zabbix can repeat executing a step several times. The figure set will equally affect each step of the scenario. Up to 10 attempts can be specified, default value is 1.</p> <p><i>Note:</i> Zabbix will not repeat a step because of a wrong response code or the mismatch of a required string.</p> |
| <i>Agent</i> | <p>Select a client agent.</p> <p>Zabbix will pretend to be the selected browser. This is useful when a website returns different content for different browsers.</p> |
| <i>HTTP proxy</i> | <p>User macros can be used in this field.</p> <p>You can specify an HTTP proxy to use, using the format [protocol://] [username[:password]@]proxy.example.com[:port].</p> <p>This sets the CURLOPT_PROXY cURL option.</p> <p>The optional protocol:// prefix may be used to specify alternative proxy protocols (the protocol prefix support was added in cURL 7.21.7). With no protocol specified, the proxy will be treated as an HTTP proxy.</p> <p>By default, 1080 port will be used.</p> <p>If specified, the proxy will overwrite proxy related environment variables like http_proxy, HTTPS_PROXY. If not specified, the proxy will not overwrite proxy-related environment variables.</p> <p>The entered value is passed on "as is", no sanity checking takes place.</p> <p>You may also enter a SOCKS proxy address. If you specify the wrong protocol, the connection will fail and the item will become unsupported.</p> <p><i>Note</i> that only simple authentication is supported with HTTP proxy.</p> |
| <i>Variables</i> | <p>User macros can be used in this field.</p> <p>Variables that may be used in scenario steps (URL, post variables).</p> <p>They have the following format:</p> <p>{macro1}=value1 {macro2}=value2 {macro3}=regex:<regular expression> {macro4}=jsonpath:<jsonpath> {macro5}=xmlxpath:<xmlxpath> {macro6}={ {macro}.function() } (see macro functions)</p> <p>For example:</p> <p>{username}=Alexei {password}=kj3h5kj34bd {hostid}=regex:hostid is ([0-9]+) {url}=jsonpath:\$.host_url {status}=xmlxpath://host/response/status {newvar}={ {myvar}.btoa() }</p> <p>The macros can then be referenced in the steps as {username}, {password}, {hostid}, etc.</p> <p>Zabbix will automatically replace them with actual values. <i>Note</i> that variables with regex: need one step to get the value of the regular expression so the extracted value can only be applied to the step after.</p> <p>If the value part starts with regex: then the part after it is treated as a regular expression that searches the web page and, if found, stores the match in the variable. At least one subgroup must be present so that the matched value can be extracted.</p> <p>User macros and {HOST.*} macros are supported.</p> <p>Variables are automatically URL-encoded when used in query fields or form data for post variables, but must be URL-encoded manually when used in raw post or directly in URL.</p> |

| Parameter | Description |
|----------------|---|
| <i>Headers</i> | <p>HTTP Headers are used when performing a request. Default and custom headers can be used. Headers will be assigned using default settings depending on the Agent type selected from a drop-down list on a scenario level, and will be applied to all the steps, unless they are custom defined on a step level.</p> <p>It should be noted that defining the header on a step level automatically discards all the previously defined headers, except for a default header that is assigned by selecting the 'User-Agent' from a drop-down list on a scenario level.</p> <p>However, even the 'User-Agent' default header can be overridden by specifying it on a step level. To unset the header on a scenario level, the header should be named and attributed with no value on a step level.</p> <p>Headers should be listed using the same syntax as they would appear in the HTTP protocol, optionally using some additional features supported by the CURLOPT_HTTPHEADER cURL option. For example:</p> <p>Accept-Charset=utf-8 Accept-Language=en-US Content-Type=application/xml; charset=utf-8 User macros and {HOST.*} macros are supported.</p> |
| <i>Enabled</i> | The scenario is active if this box is checked, otherwise - disabled. |

Note that when editing an existing scenario, two extra buttons are available in the form:

| | |
|--|---|
| Clone | Create another scenario based on the properties of the existing one. |
| Clear history and trends | Delete history and trend data for the scenario. This will make the server perform the scenario immediately after deleting the data. |

Note:

If *HTTP proxy* field is left empty, another way for using an HTTP proxy is to set proxy related environment variables. For HTTP checks - set the **http_proxy** environment variable for the Zabbix server user. For example, `http_proxy=http://proxy_ip:proxy_port`. For HTTPS checks - set the **HTTPS_PROXY** environment variable. For example, `HTTPS_PROXY=http://proxy_ip:proxy_port`. More details are available by running a shell command: `# man curl`.

The **Steps** tab allows you to configure the web scenario steps. To add a web scenario step, click on *Add* in the *Steps* block.

Scenario Steps 2 Tags Authentication

* Steps

| Name | Timeout | URL | Required | Status |

Configuring steps

Step parameters:

| Parameter | Description |
|-------------|---|
| <i>Name</i> | Unique step name. User macros are supported. Note that if user macros are used, these macros will be left unresolved in web monitoring item names. |

| Parameter | Description |
|-------------------------|---|
| <i>URL</i> | <p>URL to connect to and retrieve data. For example: https://www.example.com http://www.example.com/download</p> <p>Domain names can be specified in Unicode characters. They are automatically punycode-converted to ASCII when executing the web scenario step.</p> <p>The <i>Parse</i> button can be used to separate optional query fields (like <code>?name=Admin&password=mypassword</code>) from the URL, moving the attributes and values into <i>Query fields</i> for automatic URL-encoding.</p> <p>Variables can be used in the URL, using the <code>{macro}</code> syntax. Variables can be URL-encoded manually using a <code>{{macro}.urlencode()}</code> syntax.</p> <p>User macros and <code>{HOST.*}</code> macros are supported.</p> <p>Limited to 2048 characters.</p> |
| <i>Query fields</i> | <p>HTTP GET variables for the URL.</p> <p>Specified as attribute and value pairs.</p> <p>Values are URL-encoded automatically. Values from scenario variables, user macros or <code>{HOST.*}</code> macros are resolved and then URL-encoded automatically. Using a <code>{{macro}.urlencode()}</code> syntax will double URL-encode them.</p> <p>User macros and <code>{HOST.*}</code> macros are supported.</p> |
| <i>Post</i> | <p>HTTP POST variables.</p> <p>In Form data mode, specified as attribute and value pairs.</p> <p>Values are URL-encoded automatically. Values from scenario variables, user macros or <code>{HOST.*}</code> macros are resolved and then URL-encoded automatically.</p> <p>In Raw data mode, attributes/values are displayed on a single line and concatenated with a & symbol.</p> <p>Raw values can be URL-encoded/decoded manually using a <code>{{macro}.urlencode()}</code> or <code>{{macro}.urldecode()}</code> syntax.</p> <p>For example: <code>id=2345&userid={user}</code></p> <p>If <code>{user}</code> is defined as a variable of the web scenario, it will be replaced by its value when the step is executed. If you wish to URL-encode the variable, substitute <code>{user}</code> with <code>{{user}.urlencode()}</code>.</p> <p>User macros and <code>{HOST.*}</code> macros are supported.</p> |
| <i>Variables</i> | <p>Step-level variables that may be used for GET and POST functions.</p> <p>Specified as attribute and value pairs.</p> <p>Step-level variables override scenario-level variables or variables from the previous step.</p> <p>However, the value of a step-level variable only affects the step after (and not the current step).</p> <p>They have the following format:</p> <p>{macro}=value {macro}=regex:<regular expression></p> <p>For more information see variable description on the scenario level.</p> <p>Variables are automatically URL-encoded when used in query fields or form data for post variables, but must be URL-encoded manually when used in raw post or directly in URL.</p> |
| <i>Headers</i> | <p>Custom HTTP headers that will be sent when performing a request.</p> <p>Specified as attribute and value pairs.</p> <p>A header defined on a step level will be used for that particular step.</p> <p>It should be noted that defining the header on a step level automatically discards all the previously defined headers, except for a default header that is assigned by selecting the 'User-Agent' from a drop-down list on a scenario level.</p> <p>However, even the 'User-Agent' default header can be overridden by specifying it on a step level. For example, assigning the name to a header, but setting no value will unset the default header on a scenario level.</p> <p>User macros and <code>{HOST.*}</code> macros are supported.</p> |
| <i>Follow redirects</i> | <p>This sets the <code>CURLOPT_HTTPHEADER</code> cURL option.</p> <p>Mark the checkbox to follow HTTP redirects.</p> |
| <i>Retrieve mode</i> | <p>This sets the <code>CURLOPT_FOLLOWLOCATION</code> cURL option.</p> <p>Select the retrieve mode:</p> <p>Body - retrieve only body from the HTTP response Headers - retrieve only headers from the HTTP response Body and headers - retrieve body and headers from the HTTP response</p> |

| Parameter | Description |
|------------------------------|---|
| <i>Timeout</i> | Zabbix will not spend more than the set amount of time on processing the URL (from one second to maximum of 1 hour). Actually this parameter defines the maximum time for making connection to the URL and maximum time for performing an HTTP request. Therefore, Zabbix will not spend more than 2 x Timeout seconds on the step. Time suffixes are supported, e.g. 30s, 1m, 1h. User macros are supported. |
| <i>Required string</i> | Required regular expression pattern. Unless retrieved content (HTML) matches the required pattern the step will fail. If empty, no check on required string is performed. For example: Homepage of Zabbix Welcome.*admin Note: Referencing regular expressions created in the Zabbix frontend is not supported in this field. User macros and {HOST:*} macros are supported. |
| <i>Required status codes</i> | List of expected HTTP status codes. If Zabbix gets a code which is not in the list, the step will fail. If empty, no check on status codes is performed. For example: 200,201,210-299 User macros are supported. |

Note:

Any changes in web scenario steps will only be saved when the whole scenario is saved.

See also a [real-life example](#) of how web monitoring steps can be configured.

Configuring tags The **Tags** tab allows to define scenario-level **tags**.

The screenshot shows the 'Tags' tab in the Zabbix web scenario configuration. At the top, there are tabs for 'Scenario', 'Steps 2', 'Tags 1', and 'Authentication'. Below the tabs, there are two buttons: 'Scenario tags' (selected) and 'Inherited and scenario tags'. A table displays the configured tags:

| Name | Value | Action |
|-------------|------------|--------|
| Application | Web checks | Remove |

At the bottom left, there is an 'Add' button.

Tagging allows to filter web scenarios and web monitoring **items**.

Configuring authentication The **Authentication** tab allows you to configure scenario authentication options. A green dot next to the tab name indicates that some type of HTTP authentication is enabled.

Scenario
Steps 2
Tags 1
Authentication ●

HTTP authentication
None

SSL verify peer
☐

SSL verify host
☒

SSL certificate file

SSL key file

SSL key password

Authentication parameters:

| Parameter | Description |
|-----------------------------|--|
| <i>HTTP authentication</i> | <p>Select the authentication option:</p> <p>None - no authentication used;</p> <p>Basic - basic authentication is used;</p> <p>NTLM - NTLM (Windows NT LAN Manager) authentication is used;</p> <p>Kerberos - Kerberos authentication is used (see also: Configuring Kerberos with Zabbix);</p> <p>Digest - Digest authentication is used.</p> |
| <i>User</i> | <p>Enter the user name (up to 255 characters).</p> <p>This field is available if <i>HTTP authentication</i> is set to Basic, NTLM, Kerberos, or Digest. User macros are supported.</p> |
| <i>Password</i> | <p>Enter the user password (up to 255 characters).</p> <p>This field is available if <i>HTTP authentication</i> is set to Basic, NTLM, Kerberos, or Digest. User macros are supported.</p> |
| <i>SSL verify peer</i> | <p>Mark the checkbox to verify the SSL certificate of the web server.</p> <p>The server certificate will be automatically taken from system-wide certificate authority (CA) location. You can override the location of CA files using Zabbix server or proxy configuration parameter SSLCALocation.</p> |
| <i>SSL verify host</i> | <p>This sets the CURLOPT_SSL_VERIFYPEER cURL option.</p> <p>Mark the checkbox to verify that the <i>Common Name</i> field or the <i>Subject Alternate Name</i> field of the web server certificate matches.</p> |
| <i>SSL certificate file</i> | <p>This sets the CURLOPT_SSL_VERIFYHOST cURL option.</p> <p>Name of the SSL certificate file used for client authentication. The certificate file must be in PEM¹ format. If the certificate file contains also the private key, leave the <i>SSL key file</i> field empty. If the key is encrypted, specify the password in <i>SSL key password</i> field. The directory containing this file is specified by Zabbix server or proxy configuration parameter SSLCertLocation. HOST.* macros and user macros can be used in this field.</p> |
| <i>SSL key file</i> | <p>This sets the CURLOPT_SSLCERT cURL option.</p> <p>Name of the SSL private key file used for client authentication. The private key file must be in PEM¹ format. The directory containing this file is specified by Zabbix server or proxy configuration parameter SSLKeyLocation. HOST.* macros and user macros can be used in this field.</p> |
| <i>SSL key password</i> | <p>This sets the CURLOPT_SSLKEY cURL option.</p> <p>SSL private key file password.</p> <p>User macros can be used in this field.</p> <p>This sets the CURLOPT_KEYPASSWD cURL option.</p> |

Attention:

[1] Zabbix supports certificate and private key files in PEM format only. In case you have your certificate and private key data in PKCS #12 format file (usually with extension *.p12 or *.pfx) you may generate the PEM file from it using the following commands:

```
openssl pkcs12 -in ssl-cert.p12 -clcerts -nokeys -out ssl-cert.pem
openssl pkcs12 -in ssl-cert.p12 -nocerts -nodes -out ssl-cert.key
```

Note:

Zabbix server picks up changes in certificates without a restart.

Note:

If you have client certificate and private key in a single file just specify it in a "SSL certificate file" field and leave "SSL key file" field empty. The certificate and key must still be in PEM format. Combining certificate and key is easy:

```
cat client.crt client.key > client.pem
```

Display To view web scenarios configured for a host, go to *Monitoring* → *Hosts*, locate the host in the list and click on the *Web* hyperlink in the last column. Click on the scenario name to get detailed information.

Details of web scenario: Frontend check

| Step | Speed | Response time | Response code | Status |

An overview of web scenarios can also be displayed in *Dashboards* by the Web monitoring widget.

Recent results of the web scenario execution are available in the *Monitoring* → *Latest data* section.

Extended monitoring Sometimes it is necessary to log received HTML page content. This is especially useful if some web scenario step fails. Debug level 5 (trace) serves that purpose. This level can be set in **server** and **proxy** configuration files or using a runtime control option (`-R log_level_increase="http poller,N"`, where N is the process number). The following examples demonstrate how extended monitoring can be started provided debug level 4 is already set:

```
# Increase log level of all http pollers:
zabbix_server -R log_level_increase="http poller"
```

```
# Increase log level of second http poller:
zabbix_server -R log_level_increase="http poller,2"
```

If extended web monitoring is not required it can be stopped using the `-R log_level_decrease` option.

1 Web monitoring items

Overview

Some new items are automatically added for monitoring when web scenarios are created.

All items inherit tags from the web scenario.

Scenario items

As soon as a scenario is created, Zabbix automatically adds the following items for monitoring.

| Item | Description |
|---|---|
| <i>Download speed for scenario</i> <Scenario> | This item will collect information about the download speed (bytes per second) of the whole scenario, i.e. average for all steps. Item key: <code>web.test.in[Scenario,,bps]</code> Type: <i>Numeric(float)</i> |
| <i>Failed step of scenario</i> <Scenario> | This item will display the number of the step that failed on the scenario. If all steps are executed successfully, 0 is returned. Item key: <code>web.test.fail[Scenario]</code> Type: <i>Numeric(unsigned)</i> |
| <i>Last error message of scenario</i> <Scenario> | This item returns the last error message text of the scenario. A new value is stored only if the scenario has a failed step. If all steps are ok, no new value is collected. Item key: <code>web.test.error[Scenario]</code> Type: <i>Character</i> |

The actual scenario name will be used instead of "Scenario".

Note:

If the scenario name contains **user macros**, these macros will be left unresolved in web monitoring item names.

If the scenario name starts with a doublequote or contains a comma or a square bracket, it will be properly quoted in item keys. In other cases no additional quoting will be performed.

Note:

Web monitoring items are added with a 30 day history and a 90 day trend retention period.

These items can be used to create triggers and define notification conditions.

Example 1

To create a "Web scenario failed" trigger, you can define a trigger expression:

```
last(/host/web.test.fail[Scenario])>0
```

Make sure to replace 'Scenario' with the real name of your scenario.

Example 2

To create a "Web scenario failed" trigger with a useful problem description in the trigger name, you can define a trigger with name:

Web scenario "Scenario" failed: {ITEM.VALUE}

and trigger expression:

```
length(last(/host/web.test.error[Scenario]))>0 and last(/host/web.test.fail[Scenario])>0
```

Make sure to replace 'Scenario' with the real name of your scenario.

Example 3

To create a "Web application is slow" trigger, you can define a trigger expression:

```
last(/host/web.test.in[Scenario,,bps])<10000
```

Make sure to replace 'Scenario' with the real name of your scenario.

Scenario step items

As soon as a step is created, Zabbix automatically adds the following items for monitoring.

| Item | Description |
|--|---|
| <i>Download speed for step <Step> of scenario <Scenario></i> | This item will collect information about the download speed (bytes per second) of the step. Item key: web.test.in[Scenario,Step,bps] Type: <i>Numeric(float)</i> |
| <i>Response time for step <Step> of scenario <Scenario></i> | This item will collect information about the response time of the step in seconds. Response time is counted from the beginning of the request until all information has been transferred. Item key: web.test.time[Scenario,Step,resp] Type: <i>Numeric(float)</i> |
| <i>Response code for step <Step> of scenario <Scenario></i> | This item will collect response codes of the step. Item key: web.test.rspcode[Scenario,Step] Type: <i>Numeric(unsigned)</i> |

Actual scenario and step names will be used instead of "Scenario" and "Step" respectively.

Note:

Web monitoring items are added with a 30 day history and a 90 day trend retention period.

Note:

If scenario name starts with a doublequote or contains comma or square bracket, it will be properly quoted in item keys. In other cases no additional quoting will be performed.

These items can be used to create triggers and define notification conditions. For example, to create a "Zabbix GUI login is too slow" trigger, you can define a trigger expression:

```
last(/zabbix/web.test.time[ZABBIX GUI,Login,resp])>3
```

2 Real-life scenario

Overview

This section presents a step-by-step real-life example of how web monitoring can be used.

Zabbix web monitoring will be used to monitor Zabbix frontend. The goal is to determine if it is available, provides the right content, and how quickly it works. To achieve this, several steps are required, including checking the availability of the first page, logging in with a username and password, verifying the login success, logging out, and confirming the logout.

Scenario

Add a new web scenario

Go to *Data collection* → *Hosts*, pick a host and click on *Web* in the row of that host. Then click on *Create web scenario*.

Scenario
Steps

| {user} | ⇒ | zbx_monitor |

Add

Headers

| Name | | Value |
|------|---|-------|
| name | ⇒ | value |

Add

Enabled
☒

Add
Cancel

In the new scenario form, fill out the following fields:

- **Name** - Frontend check
- **Update interval** - 1m
- **Attempts** - 1
- **Agent** - Zabbix

In the *Variables* section, add two variables: `{password}` and `{user}`. Enter your existing Zabbix user credentials as values.

For safety reasons, it is recommended to create a separate user with minimal permissions to use for monitoring purposes.

Optionally, switch to the *Tags* tab and add web scenario tags.

Note:

Once fully configured, this web scenario will automatically add a Zabbix trapper item to the host. You can use web scenario tags to quickly identify related items and triggers or search through collected data. For example, suitable tags for this tutorial are `component: web-scenario` and/or `target: frontend`.

Configure web scenario steps

Switch to the *Steps* tab and define steps for the scenario. Click on *Add* button to add an individual step.

Common fields

For each step described below, fill out the following fields in addition to the step-specific fields:

- **URL** - the URL of Zabbix frontend
- **Timeout** - 15s
- **Required status codes** - 200

Web scenario step 1

Check that the first page responds correctly, returns HTTP response code 200 and contains the text "Zabbix SIA".

- In the **Name** field, enter *First page*.
- In the **Required string** field, enter *Zabbix SIA*.
- Fill out the **common fields**.

When done configuring the step, press the *Add* button.

Web scenario step 2

Log in to the Zabbix frontend using the macros (variables) defined at the scenario level - *{user}* and *{password}*.

- In the **Name** field, enter *Login*.
- In the **Post fields** section, add three post fields:
 - *name* with value *{user}*
 - *password* with value *{password}*
 - *enter* with value *Sign in*
- In the **Variables** section, add a new variable *{csrf_token}* with value *regex:([0-9a-z]{64})*. This variable will catch the value of the assigned CSRF token to reuse in **step 4**.
- Fill out the **common fields**.

Attention:

Note that Zabbix frontend uses JavaScript redirect when logging in, so login must occur first, and logged-in features can be checked only in further steps. Additionally, the login step must use the full URL to **index.php** file.

Web scenario step 3

After logging in, verify success by checking for a string visible only when logged in - for example, *Administration*.

- In the **Name** field, enter *Login check*.
- In the **Required string** field, enter *Administration*.
- Fill out the **common fields**.

Web scenario step 4

Once the frontend's accessibility and login have been verified, add a logout step - otherwise the Zabbix database will become cluttered with many open session records.

- In the **Name** field, enter *Logout*.
- In the **Post fields** section, add two post fields:
 - *reconnect* with value *1*
 - *_csrf_token* with value *{csrf_token}*.
- Fill out the **common fields**.

This step uses the variable `{csrf_token}` obtained in **step 2**

Full configuration of steps

A complete configuration of web scenario steps should look like this:

| | Name | Timeout | URL | Required | Status codes | Action |
|----|---------------------|---------|----------------------------|-----------------|--------------|------------------------|
| 1: | First page | 15s | http://127.0.0.1/index.php | Zabbix SIA | 200 | Remove |
| 2: | Log in | 15s | http://127.0.0.1/index.php | | 200 | Remove |
| 3: | Log in Check | 15s | http://127.0.0.1/index.php | Administrati... | 200 | Remove |
| 4: | Log out | 15s | http://127.0.0.1/index.php | | 200 | Remove |
| 5: | Log out check | 15s | http://127.0.0.1/index.php | Username | 200 | Remove |
| | Add | | | | | |

Check the results

Save the finished web monitoring scenario.

The scenario will be added to the host. To view web scenario information go to *Monitoring* → *Hosts*, locate the host in the list and click on the Web hyperlink in the last column.

10 Virtual machine monitoring

Overview Zabbix can use low-level discovery rules to automatically discover VMware hypervisors and virtual machines, and create hosts to monitor them based on pre-defined host prototypes.

Zabbix also includes ready-to-use templates for monitoring VMware vCenter or ESXi hypervisors.

The minimum required VMware vCenter or vSphere version is 5.1.

Data collection Virtual machine monitoring consists of two steps:

1. Zabbix *vmware collector* processes collect virtual machine data - the processes obtain necessary information from VMware web services over the SOAP protocol, pre-process it, and store it in Zabbix server shared memory.
2. Zabbix *poller* processes retrieve data using Zabbix simple check [VMware monitoring item keys](#).

Zabbix divides collected data into VMware configuration data and VMware performance counter data. Both types of data are collected independently by the *vmware collector* processes.

The following statistics are available based on the VMware performance counter information:

- Datastore
- Disk device
- CPU
- Power
- Network interface
- Custom performance counter items

For the complete list of items that obtain data from VMware performance counters, see [VMware monitoring item keys](#).

Note that the frequency of VMware event retrieval depends on the polling interval of `vmware.eventlog`, but cannot be less than 5 seconds.

Configuration If Zabbix server is compiled from [sources](#), it must be compiled with the `--with-libcurl --with-libxml2` configuration options to enable virtual machine monitoring. Zabbix packages are compiled with these options already enabled.

The following Zabbix server configuration file parameters can be modified for virtual machine monitoring:

- `StartVMwareCollectors`

Note:

It is recommended to enable more collectors than the number of monitored VMware services; otherwise, the retrieval of VMware performance counter statistics might be delayed by the retrieval of VMware configuration data (which takes a while for large installations).
 Generally, the value of `StartVMwareCollectors` should not dip below 2 and should not exceed twice the amount of monitored VMware services: $\text{Amount of services} < \text{StartVMwareCollectors} < (\text{Amount of services} * 2)$. For example, when monitoring one VMware service, set `StartVMwareCollectors` to 2; when monitoring three services, set `StartVMwareCollectors` to 5.
 Note that the required number of collectors also depends on the scope of the VMware environment, and the `VMwareFrequency` and `VMwarePerfFrequency` configuration parameters.

- `VMwareCacheSize`
- `VMwareFrequency`
- `VMwarePerfFrequency`
- `VMwareTimeout`

Attention:

To support datastore capacity metrics, ensure that the value of the VMware `vpdx.stats.maxQueryMetrics` key is set to at least 64. For more information, see the [VMware Knowledge Base article](#).

Discovery

Zabbix can use low-level discovery rules (for example, `vmware.hv.discovery[{$VMWARE.URL}]`) to automatically discover VMware hypervisors and virtual machines. Moreover, Zabbix can use host prototypes to automatically generate real hosts for the discovered entities. For more information, see [Host prototypes](#).

Configuration examples

For a basic example of how to set up Zabbix for monitoring VMware using the *VMware FQDN* template, see [Monitor VMware with Zabbix](#).

For a more detailed example of how to create a host, a low-level discovery rule, and a host prototype for monitoring VMware, see [Setup example](#).

Extended logging The data collected by the *vmware collector* processes can be logged for detailed debugging using debug level 5. The debug level can be configured in the [server](#) and [proxy](#) configuration files or using the runtime control option `-R log_level_increase="vmware collector,N"`, where "N" is the process number.

For example, to increase the debug level from 4 to 5 for all *vmware collector* processes, run the following command:

```
zabbix_server -R log_level_increase="vmware collector"
```

To increase the debug level from 4 to 5 for the second *vmware collector* process, run the following command:

```
zabbix_server -R log_level_increase="vmware collector,2"
```

When extended logging of VMware collector data is no longer required, it is recommended to decrease the debug level to default (3) by running the `-R log_level_decrease` command.

Troubleshooting

- In case of unavailable metrics, please ensure that they are not made unavailable or turned off by default in recent VMware vSphere versions, or if some limits are not placed on performance-metric database queries. For more information, see [ZBX-12094](#).
- If `config.vpxd.stats.maxQueryMetrics` is invalid or exceeds the maximum number of characters permitted error, add a `config.vpxd.stats.maxQueryMetrics` parameter to the vCenter Server settings. The value of this parameter should be the same as the value of `maxQuerysize` in VMware's *web.xml* file. For more information, see [VMware Knowledge Base article](#).
- If you suspect your Zabbix installation is using too much memory, see [Profiling excessive memory usage with tcmmalloc](#).

1 VMware monitoring item keys

Overview This page provides details on the simple checks that can be used to monitor **VMware environments**. The metrics are grouped by the monitoring target.

Supported item keys The item keys are listed without parameters and additional information. Click on the item key to see the full details.

| Item key | Description | Item group |
|---|---|----------------------------|
| vmware.eventlog | The VMware event log. | General service |
| vmware.fullname | The VMware service full name. | Cluster |
| vmware.version | The VMware service version. | |
| vmware.cl.perfcouter | The VMware cluster performance counter metrics. | |
| vmware.cluster.alarms.get | The VMware cluster alarms data. | |
| vmware.cluster.discovery | The discovery of VMware clusters. | |
| vmware.cluster.property | The VMware cluster property. | Datastore |
| vmware.cluster.status | The VMware cluster status. | |
| vmware.cluster.tags.get | The VMware cluster tags array. | |
| vmware.datastore.alarms.get | The VMware datastore alarms data. | |
| vmware.datastore.discovery | The discovery of VMware datastores. | |
| vmware.datastore.hv.list | The list of datastore hypervisors. | Datacenter |
| vmware.datastore.perfcouter | The VMware datastore performance counter value. | |
| vmware.datastore.property | The VMware datastore property. | |
| vmware.datastore.read | The amount of time for a read operation from the datastore. | |
| vmware.datastore.size | The VMware datastore space in bytes or in percentage from total. | |
| vmware.datastore.tags.get | The VMware datastore tags array. | vSphere Distributed Switch |
| vmware.datastore.write | The amount of time for a write operation to the datastore. | |
| vmware.dc.alarms.get | The VMware datacenter alarms data. | |
| vmware.dc.discovery | The discovery of VMware datacenters. | |
| vmware.dc.tags.get | The VMware datacenter tags array. | |
| vmware.dvswitch.discovery | The discovery of VMware vSphere Distributed Switches. | Hypervisor |
| vmware.dvswitch.fetchports | The VMware vSphere Distributed Switch ports data. | |
| vmware.hv.alarms.get | The VMware hypervisor alarms data. | |
| vmware.hv.cluster.name | The VMware hypervisor cluster name. | |
| vmware.hv.connectionstate | The VMware hypervisor connection state. | |
| vmware.hv.cpu.usage | The VMware hypervisor processor usage (Hz). | |
| vmware.hv.cpu.usage.perf | The VMware hypervisor processor usage as a percentage during the interval. | |
| vmware.hv.cpu.utilization | The VMware hypervisor processor usage as a percentage during the interval, depends on power management or HT. | |
| vmware.hv.datacenter.name | The VMware hypervisor datacenter name. | |

| Item key | Description | Item group |
|----------------------------------|---|-----------------|
| vmware.hv.datastore.discovery | The discovery of VMware hypervisor datastores. | Resource pool |
| vmware.hv.datastore.list | The list of VMware hypervisor datastores. | |
| vmware.hv.datastore.multipath | The number of available datastore paths. | |
| vmware.hv.datastore.read | The average amount of time for a read operation from the datastore. | |
| vmware.hv.datastore.size | The VMware datastore space in bytes or in percentage from total. | |
| vmware.hv.datastore.write | The average amount of time for a write operation to the datastore. | |
| vmware.hv.discovery | The discovery of VMware hypervisors. | |
| vmware.hv.diskinfo.get | The VMware hypervisor disk data. | |
| vmware.hv.fullname | The VMware hypervisor name. | |
| vmware.hv.hw.cpu.freq | The VMware hypervisor processor frequency. | |
| vmware.hv.hw.cpu.model | The VMware hypervisor processor model. | |
| vmware.hv.hw.cpu.num | The number of processor cores on VMware hypervisor. | |
| vmware.hv.hw.cpu.threads | The number of processor threads on VMware hypervisor. | |
| vmware.hv.hw.memory | The VMware hypervisor total memory size. | |
| vmware.hv.hw.model | The VMware hypervisor model. | |
| vmware.hv.hw.sensors.get | The VMware hypervisor hardware sensors value. | |
| vmware.hv.hw.serialnumber | The VMware hypervisor serial number. | |
| vmware.hv.hw.uuid | The VMware hypervisor BIOS UUID. | |
| vmware.hv.hw.vendor | The VMware hypervisor vendor name. | |
| vmware.hv.maintenance | The VMware hypervisor maintenance status. | |
| vmware.hv.memory.size.balloon | The VMware hypervisor ballooned memory size. | |
| vmware.hv.memory.used | The VMware hypervisor used memory size. | |
| vmware.hv.net.if.discovery | The discovery of VMware hypervisor network interfaces. | |
| vmware.hv.network.in | The VMware hypervisor network input statistics. | |
| vmware.hv.network.linkspeed | The VMware hypervisor network interface speed. | |
| vmware.hv.network.out | The VMware hypervisor network output statistics. | |
| vmware.hv.perfcounter | The VMware hypervisor performance counter value. | |
| vmware.hv.property | The VMware hypervisor property. | |
| vmware.hv.power | The VMware hypervisor power usage. | |
| vmware.hv.sensor.health.state | The VMware hypervisor health state rollup sensor. | |
| vmware.hv.sensors.get | The VMware hypervisor HW vendor state sensors. | |
| vmware.hv.status | The VMware hypervisor status. | |
| vmware.hv.tags.get | The VMware hypervisor tags array. | |
| vmware.hv.uptime | The VMware hypervisor uptime. | |
| vmware.hv.version | The VMware hypervisor version. | |
| vmware.hv.vm.num | The number of virtual machines on the VMware hypervisor. | |
| vmware.rp.cpu.usage | The CPU usage in hertz during the interval on VMware Resource Pool. | |
| vmware.rp.memory | The memory metrics of VMware resource pool. | Virtual center |
| vmware.alarms.get | The VMware virtual center alarms data. | |
| vmware.vm.alarms.get | The VMware virtual machine alarms data. | Virtual machine |
| vmware.vm.attribute | The VMware virtual machine custom attribute value. | |
| vmware.vm.cluster.name | The VMware virtual machine name. | |
| vmware.vm.consolidationneeded | The VMware virtual machine disk requires consolidation. | |
| vmware.vm.cpu.latency | The percentage of time the virtual machine is unable to run because it is contending for access to the physical CPU(s). | |
| vmware.vm.cpu.num | The number of processors on VMware virtual machine. | |
| vmware.vm.cpu.readiness | The percentage of time that the virtual machine was ready, but could not get scheduled to run on the physical CPU. | |
| vmware.vm.cpu.ready | The time that the virtual machine was ready, but could not get scheduled to run on the physical CPU. | |
| vmware.vm.cpu.swapwait | The percentage of CPU time spent waiting for swap-in. | |
| vmware.vm.cpu.usage | The VMware virtual machine processor usage (Hz). | |
| vmware.vm.cpu.usage.per | The VMware virtual machine processor usage as a percentage during the interval. | |
| vmware.vm.datacenter.name | The VMware virtual machine datacenter name. | |
| vmware.vm.discovery | The discovery of VMware virtual machines. | |
| vmware.vm.guest.memory.size.swap | The amount of guest physical memory that is swapped out to the swap space. | |
| vmware.vm.guest.osuptime | The total time elapsed since the last operating system boot-up. | |
| vmware.vm.hv.maintenance | The VMware virtual machine hypervisor maintenance status. | |

| Item key | Description | Item group |
|-----------------------------------|--|------------|
| vmware.vm.hv.name | The VMware virtual machine hypervisor name. | |
| vmware.vm.memory.size | The VMware virtual machine total memory size. | |
| vmware.vm.memory.size.balloon | The VMware virtual machine ballooned memory size. | |
| vmware.vm.memory.size.compressed | The VMware virtual machine compressed memory size. | |
| vmware.vm.memory.size.committed | The amount of host physical memory consumed for backing up guest physical memory pages. | |
| vmware.vm.memory.size.private | The VMware virtual machine private memory size. | |
| vmware.vm.memory.size.shared | The VMware virtual machine shared memory size. | |
| vmware.vm.memory.size.swapped | The VMware virtual machine swapped memory size. | |
| vmware.vm.memory.size.usage.guest | The VMware virtual machine guest memory usage. | |
| vmware.vm.memory.size.usage.host | The VMware virtual machine host memory usage. | |
| vmware.vm.memory.usage | The percentage of host physical memory that has been consumed. | |
| vmware.vm.net.if.discovery | The discovery of VMware virtual machine network interfaces. | |
| vmware.vm.net.if.in | The VMware virtual machine network interface input statistics. | |
| vmware.vm.net.if.out | The VMware virtual machine network interface output statistics. | |
| vmware.vm.net.if.usage | The VMware virtual machine network utilization during the interval. | |
| vmware.vm.perfcounter | The VMware virtual machine performance counter value. | |
| vmware.vm.powerstate | The VMware virtual machine power state. | |
| vmware.vm.property | The VMware virtual machine property. | |
| vmware.vm.snapshot.get | The VMware virtual machine snapshot state. | |
| vmware.vm.state | The VMware virtual machine state. | |
| vmware.vm.storage.committed | The VMware virtual machine committed storage space. | |
| vmware.vm.storage.reads | The average number of outstanding read requests to the virtual disk during the collection interval. | |
| vmware.vm.storage.read.latency | The average time a read from the virtual disk takes. | |
| vmware.vm.storage.write.latency | The average time a write to the virtual disk takes. | |
| vmware.vm.storage.uncommitted | The VMware virtual machine uncommitted storage space. | |
| vmware.vm.storage.unshared | The VMware virtual machine unshared storage space. | |
| vmware.vm.storage.writes | The average number of outstanding write requests to the virtual disk during the collection interval. | |
| vmware.vm.tags.get | The VMware virtual machine tags array. | |
| vmware.vm.tools | The VMware virtual machine guest tools state or version. | |
| vmware.vm.uptime | The VMware virtual machine uptime. | |
| vmware.vm.vfs.dev.discovery | The discovery of VMware virtual machine disk devices. | |
| vmware.vm.vfs.dev.read | The VMware virtual machine disk device read statistics. | |
| vmware.vm.vfs.dev.write | The VMware virtual machine disk device write statistics. | |
| vmware.vm.vfs.fs.discovery | The discovery of VMware virtual machine file systems. | |
| vmware.vm.vfs.fs.size | The VMware virtual machine file system statistics. | |

Item key details Parameters without angle brackets are mandatory. Parameters marked with angle brackets < > are optional.

vmware.eventlog[url,<mode>,<severity>]

 The VMware event log.
 Return value: *Log*.

Parameters:

- **url** - the VMware service URL;
- **mode** - *all* (default) or *skip* - skip the processing of older data;
- **severity** - filter by severity: *error*, *warning*, *info* or *user*. This parameter must be quoted if more than one severity is specified in a comma-delimited list (e.g. "error,warning,info,user"). Disabled by default.

Comments:

- There must be only one vmware.eventlog item key per URL;
- See also [example of filtering VMware event log records](#).

vmware.fullnameurl

 The VMware service full name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL.

vmware.versionurl

 The VMware service version.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL.

`vmware.cl.perfcounter[url,id,path,<instance>]`

 The VMware cluster performance counter metrics.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **id** - the VMware cluster ID. id can be received from `vmware.cluster.discovery[]` as `{#CLUSTER.ID}`.
- **path** - the performance counter path¹;
- **instance** - the performance counter instance.

`vmware.cluster.alarms.get[url,id]`

 The VMware cluster alarms data.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **id** - the VMware cluster ID.

`vmware.cluster.discoveryurl`

 The discovery of VMware clusters.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL.

`vmware.cluster.property[url,id,prop]`

 The VMware cluster property.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **id** - the VMware cluster ID;
- **prop** - the property path which is the name of a property of the VM object as defined in the [VMware SDK](#).

Examples:

```
vmware.vm.property[{$VMWARE.URL},{ $VMWARE.VM.UUID},overallStatus]
vmware.vm.property[{$VMWARE.URL},{ $VMWARE.VM.UUID},runtime.powerState]
```

`vmware.cluster.status[url,name]`

 The VMware cluster status.
 Return value: 0 - gray; 1 - green; 2 - yellow; 3 - red.

Parameters:

- **url** - the VMware service URL;
- **name** - the VMware cluster name.

`vmware.cluster.tags.get[url,id]`

 The VMware cluster tags array.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **id** - the VMware cluster ID.

This item works with vSphere 6.5 and newer.

`vmware.datastore.alarms.get[url,uuid]`

 The VMware datastore alarms data.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware datastore global unique identifier.

vmware.datastore.discovery[url,<filter_uuid>]

 The discovery of VMware datastores.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **filter_uuid** - a single HV or VM unique identifier (default: empty). If specified, only linked datastores will be discovered.

vmware.datastore.hv.list[url,datastore]

 The list of datastore hypervisors.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **datastore** - the datastore UUID or name.

Output example:

esx7-01-host.zabbix.sandbox

esx7-02-host.zabbix.sandbox

vmware.datastore.perfcounter[url,uuid,path,<instance>]

 The VMware datastore performance counter value.
 Return value: *Integer* ².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware datastore global unique identifier;
- **path** - the performance counter path ¹;
- **instance** - the performance counter instance. Use empty instance for aggregate values (default). *instance* can be received from `vmware.datastore.discovery[]` as part of the `{#DATASTORE.EXTENT}` array.

vmware.datastore.property[url,uuid,prop]

 The VMware datastore property.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware datastore global unique identifier;
- **prop** - the property path.

vmware.datastore.read[url,datastore,<mode>]

 The amount of time for a read operation from the datastore (milliseconds).
 Return value: *Integer* ².

Parameters:

- **url** - the VMware service URL;
- **datastore** - the datastore UUID or name;
- **mode** - *latency* (average value, default) or *maxlatency* (maximum value).

vmware.datastore.size[url,datastore,<mode>]

 The VMware datastore space in bytes or in percentage from total.
 Return value: *Integer* - for bytes; *Float* - for percentage.

Parameters:

- **url** - the VMware service URL;
- **datastore** - the datastore UUID or name;
- **mode** - possible values: *total* (default), *free*, *pfree* (free percentage), *uncommitted*.

vmware.datastore.tags.get[url,uuid]

 The VMware datastore tags array.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware datastore global unique identifier.

This item works with vSphere 6.5 and newer.

vmware.datastore.write[url,datastore,<mode>]

 The amount of time for a write operation to the datastore (milliseconds).
 Return value: *Integer* ².

Parameters:

- **url** - the VMware service URL;
- **datastore** - the datastore UUID or name;
- **mode** - *latency* (average value, default) or *maxlatency* (maximum value).

vmware.dc.alarms.get[url,id]

 The VMware datacenter alarms data.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **id** - the VMware datacenter ID.

vmware.dc.discoveryurl

 The discovery of VMware datacenters.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL.

vmware.dc.tags.get[url,id]

 The VMware datacenter tags array.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **id** - the VMware datacenter ID.

This item works with vSphere 6.5 and newer.

vmware.dvswitch.discoveryurl

 The discovery of VMware vSphere Distributed Switches.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL.

vmware.dvswitch.fetchports.get[url,uuid,<filter>,<mode>]

 The VMware vSphere Distributed Switch ports data.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware DVSwitch global unique identifier.
- **filter** - a single string with comma-separated criteria for selecting ports;
- **mode** - *state* (all XML without "config" XML nodes, default) or *full*.

The **filter** parameter supports the **criteria** available in the VMware data object DistributedVirtualSwitchPortCriteria.

Example:

vmware.dvswitch.fetchports.get[{\$VMWARE.URL},{ \$VMWARE.DVS.UUID},"connected:true,active:true,uplinkPort:fail"]

vmware.hv.alarms.get[url,uuid]

 The VMware hypervisor alarms data.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.cluster.name[url,uuid]

 The VMware hypervisor cluster name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.connectionstate[url,uuid]

 The VMware hypervisor connection state.
 Return value: *String*: *connected*, *disconnected*, or *notResponding*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.cpu.usage[url,uuid]

 The VMware hypervisor processor usage (Hz).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.cpu.usage.perf[url,uuid]

 The VMware hypervisor processor usage as a percentage during the interval.
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.cpu.utilization[url,uuid]

 The VMware hypervisor processor usage as a percentage during the interval, depends on power management or HT.
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.datacenter.name[url,uuid]

 The VMware hypervisor datacenter name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.datastore.discovery[url,uuid]

 The discovery of VMware hypervisor datastores.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.datastore.list[url,uuid]

 The list of VMware hypervisor datastores.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

Output example:

SSD-RAID1-VAULT1
SSD-RAID1-VAULT2
SSD-RAID10

vmware.hv.datastore.multipath[url,uuid,<datastore>,<partitionid>]

 The number of available datastore paths.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **datastore** - the datastore UUID or name;

- **partitionid** - the internal ID of physical device from `vmware.hv.datastore.discovery`.

`vmware.hv.datastore.read[url,uuid,datastore,<mode>]`

 The average amount of time for a read operation from the datastore (milliseconds).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **datastore** - the datastore UUID or name;
- **mode** - *latency* (default).

`vmware.hv.datastore.size[url,uuid,datastore,<mode>]`

 The VMware datastore space in bytes or in percentage from total.
 Return value: *Integer* - for bytes; *Float* - for percentage.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **datastore** - the datastore UUID or name;
- **mode** - possible values: *total* (default), *free*, *pfree* (free percentage), *uncommitted*.

`vmware.hv.datastore.write[url,uuid,datastore,<mode>]`

 The average amount of time for a write operation to the datastore (milliseconds).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **datastore** - the datastore UUID or name;
- **mode** - *latency* (default).

`vmware.hv.discoveryurl`

 The discovery of VMware hypervisors.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL.

`vmware.hv.diskinfo.get[url,uuid]`

 The VMware hypervisor disk data.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

`vmware.hv.fullname[url,uuid]`

 The VMware hypervisor name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

`vmware.hv.hw.cpu.freq[url,uuid]`

 The VMware hypervisor processor frequency (Hz).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

`vmware.hv.hw.cpu.model[url,uuid]`

 The VMware hypervisor processor model.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.hw.cpu.num[url,uuid]

 The number of processor cores on VMware hypervisor.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.hw.cpu.threads[url,uuid]

 The number of processor threads on VMware hypervisor.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.hw.memory[url,uuid]

 The VMware hypervisor total memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.hw.model[url,uuid]

 The VMware hypervisor model.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.hw.sensors.get[url,uuid]

 The VMware hypervisor hardware sensors value.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.hw.serialNumber[url,uuid]

 The VMware hypervisor serial number.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

This item works with vSphere API 6.7 and newer.

vmware.hv.hw.uuid[url,uuid]

 The VMware hypervisor BIOS UUID.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

This item works with vSphere API 6.7 and newer.

vmware.hv.hw.vendor[url,uuid]

 The VMware hypervisor vendor name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

This item works with vSphere API 6.7 and newer.

vmware.hv.maintenance[url,uuid]

 The VMware hypervisor maintenance status.
 Return value: *0* - not in maintenance; *1* - in maintenance.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.memory.size.ballooned[url,uuid]

 The VMware hypervisor ballooned memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.memory.used[url,uuid]

 The VMware hypervisor used memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.net.if.discovery[url,uuid]

 The discovery of VMware hypervisor network interfaces.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.network.in[url,uuid,<mode>]

 The VMware hypervisor network input statistics (bytes per second).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **mode** - *bps* (default), *packets*, *dropped*, *errors*, *broadcast*.

vmware.hv.network.linkspeed[url,uuid,ifname]

 The VMware hypervisor network interface speed.
 Return value: *Integer*. Returns 0, if the network interface is down, otherwise the speed value of the interface.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **ifname** - the interface name.

vmware.hv.network.out[url,uuid,<mode>]

 The VMware hypervisor network output statistics (bytes per second).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **mode** - *bps* (default), *packets*, *dropped*, *errors*, *broadcast*.

vmware.hv.perfcounter[url,uuid,path,<instance>]

 The VMware hypervisor performance counter value.
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **path** - the performance counter path¹;
- **instance** - the performance counter instance. Use empty instance for aggregate values (default).

vmware.hv.property[url,uuid,prop]

 The VMware hypervisor property.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **prop** - the property path.

vmware.hv.power[url,uuid,<max>]

 The VMware hypervisor power usage (W).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier;
- **max** - the maximum allowed power usage.

vmware.hv.sensor.health.state[url,uuid]

 The VMware hypervisor health state rollup sensor.
 Return value: *Integer*: 0 - gray; 1 - green; 2 - yellow; 3 - red.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

Note that the item might not work in VMware vSphere 6.5 and newer, because VMware has deprecated the *VMware Rollup Health State* sensor.

vmware.hv.sensors.get[url,uuid]

 The VMware hypervisor HW vendor state sensors.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.status[url,uuid]

 The VMware hypervisor status.
 Return value: *Integer*: 0 - gray; 1 - green; 2 - yellow; 3 - red.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

This item uses the host system overall status property.

vmware.hv.tags.get[url,uuid]

 The VMware hypervisor tags array.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

This item works with vSphere 6.5 and newer.

vmware.hv.uptime[url,uuid]

 The VMware hypervisor uptime (seconds).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

This item uses the host system overall status property.

vmware.hv.version[url,uuid]

 The VMware hypervisor version.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.hv.vm.num[url,uuid]

 The number of virtual machines on the VMware hypervisor.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware hypervisor global unique identifier.

vmware.rp.cpu.usage[url,rpId]

 The CPU usage in hertz during the interval on VMware Resource Pool.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **rpId** - the VMware resource pool ID.

vmware.rp.memory[url,rpId,<mode>]

 The memory metrics of VMware resource pool.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **rpId** - the VMware resource pool ID;
- **mode** - possible values:
consumed (default) - the amount of host physical memory consumed for backing up guest physical memory pages
ballooned - the amount of guest physical memory reclaimed from the virtual machine by the balloon driver in the guest
overhead - the host physical memory consumed by ESXi data structures for running the virtual machines

vmware.alarms.geturl

 The VMware virtual center alarms data.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL.

vmware.vm.alarms.get[url,uuid]

 The VMware virtual machine alarms data.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.attribute[url,uuid,name]

 The VMware virtual machine custom attribute value.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **name** - the custom attribute name.

vmware.vm.cluster.name[url,uuid]

 The VMware virtual machine name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **name** - the custom attribute name.

vmware.vm.consolidationneeded[url,uuid]

 The VMware virtual machine disk requires consolidation.
 Return value: *String*: *true* - consolidation is needed; *false* - consolidation is not needed.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.cpu.latency[url,uuid]

 The percentage of time the virtual machine is unable to run because it is contending for access to the physical CPU(s).
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.cpu.num[url,uuid]

 The number of processors on VMware virtual machine.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.cpu.readiness[url,uuid,<instance>]

 The percentage of time that the virtual machine was ready, but could not get scheduled to run on the physical CPU.
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the CPU instance.

vmware.vm.cpu.ready[url,uuid]

 The time (in milliseconds) that the virtual machine was ready, but could not get scheduled to run on the physical CPU. CPU ready time is dependent on the number of virtual machines on the host and their CPU loads (%).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.cpu.swapwait[url,uuid,<instance>]

 The percentage of CPU time spent waiting for swap-in.
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the CPU instance.

vmware.vm.cpu.usage[url,uuid]

 The VMware virtual machine processor usage (Hz).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.cpu.usage.perf[url,uuid]

 The VMware virtual machine processor usage as a percentage during the interval.
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.datacenter.name[url,uuid]

 The VMware virtual machine datacenter name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.discoveryurl

 The discovery of VMware virtual machines.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL.

vmware.vm.guest.memory.size.swapped[url,uuid]

 The amount of guest physical memory that is swapped out to the swap space (KB).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.guest.osuptime[url,uuid]

 The total time elapsed since the last operating system boot-up (in seconds).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.hv.maintenance[url,uuid]

 The VMware virtual machine hypervisor maintenance status.
 Return value: *0* - not in maintenance; *1* - in maintenance.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.hv.name[url,uuid]

 The VMware virtual machine hypervisor name.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size[url,uuid]

 The VMware virtual machine total memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.ballooned[url,uuid]

 The VMware virtual machine ballooned memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.compressed[url,uuid]

 The VMware virtual machine compressed memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.consumed[url,uuid]

 The amount of host physical memory consumed for backing up guest physical memory pages (KB).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.private[url,uuid]

 The VMware virtual machine private memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.shared[url,uuid]

 The VMware virtual machine shared memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.swapped[url,uuid]

 The VMware virtual machine swapped memory size (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.usage.guest[url,uuid]

 The VMware virtual machine guest memory usage (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.size.usage.host[url,uuid]

 The VMware virtual machine host memory usage (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.memory.usage[url,uuid]

 The percentage of host physical memory that has been consumed.
 Return value: *Float*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.net.if.discovery[url,uuid]

 The discovery of VMware virtual machine network interfaces.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.net.if.in[url,uuid,instance,<mode>]

 The VMware virtual machine network interface input statistics (bytes/packets per second).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the network interface instance;
- **mode** - *bps* (default) or *pps* - bytes or packets per second.

vmware.vm.net.if.out[url,uuid,instance,<mode>]

 The VMware virtual machine network interface output statistics (bytes/packets per second).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the network interface instance;
- **mode** - *bps* (default) or *pps* - bytes or packets per second.

vmware.vm.net.if.usage[url,uuid,<instance>]

 The VMware virtual machine network utilization (combined transmit-rates and receive-rates) during the interval (KBps).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the network interface instance.

vmware.vm.perfcounter[url,uuid,path,<instance>]

 The VMware virtual machine performance counter value.
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **path** - the performance counter path¹;
- **instance** - the performance counter instance. Use empty instance for aggregate values (default).

vmware.vm.powerstate[url,uuid]

 The VMware virtual machine power state.
 Return value: 0 - poweredOff; 1 - poweredOn; 2 - suspended.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.property[url,uuid,prop]

 The VMware virtual machine property.
 Return value: *String*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **prop** - the property path.

vmware.vm.snapshot.get[url,uuid]

 The VMware virtual machine snapshot state.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.state[url,uuid]

 The VMware virtual machine state.
 Return value: *String*: *notRunning*, *resetting*, *running*, *shuttingDown*, *standby*, or *unknown*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.storage.committed[url,uuid]

 The VMware virtual machine committed storage space (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.storage.readoio[url,uuid,instance]

 The average number of outstanding read requests to the virtual disk during the collection interval.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the disk device instance.

vmware.vm.storage.totalreadlatency[url,uuid,instance]

 The average time a read from the virtual disk takes (milliseconds).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the disk device instance.

vmware.vm.storage.totalwritelatency[url,uuid,instance]

 The average time a write to the virtual disk takes (milliseconds).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the disk device instance.

vmware.vm.storage.uncommitted[url,uuid]

 The VMware virtual machine uncommitted storage space (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.storage.unshared[url,uuid]

 The VMware virtual machine unshared storage space (bytes).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.storage.writeio[url,uuid,instance]

 The average number of outstanding write requests to the virtual disk during the collection interval.
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the disk device instance.

vmware.vm.tags.get[url,uuid]

 The VMware virtual machine tags array.
 Return value: **JSON object**.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

This item works with vSphere 6.5 and newer.

vmware.vm.tools[url,uuid,<mode>]

 The VMware virtual machine guest tools state.
 Return value: *String*.
 In *status* mode: *guestToolsExecutingScripts* - VMware Tools is starting; *guestToolsNotRunning* - VMware Tools is not running; *guestToolsRunning* - VMware Tools is running.
 In *version* mode: *version*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **mode** - *version*, *status* (default).

vmware.vm.uptime[url,uuid]

 The VMware virtual machine uptime (seconds).
 Return value: *Integer*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.vfs.dev.discovery[url,uuid]

 The discovery of VMware virtual machine disk devices.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

vmware.vm.vfs.dev.read[url,uuid,instance,<mode>]

 The VMware virtual machine disk device read statistics (bytes/operations per second).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the disk device instance;
- **mode** - *bps* (default) or *ops* - bytes or operations per second.

vmware.vm.vfs.dev.write[url,uuid,instance,<mode>]

 The VMware virtual machine disk device write statistics (bytes/operations per second).
 Return value: *Integer*².

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **instance** - the disk device instance;
- **mode** - *bps* (default) or *ops* - bytes or operations per second.

vmware.vm.vfs.fs.discovery[url,uuid]

 The discovery of VMware virtual machine file systems.
 Return value: *JSON object*.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier.

VMware Tools must be installed on the guest virtual machine for this item to work.

vmware.vm.vfs.fs.size[url,uuid,fsname,<mode>]

 The VMware virtual machine file system statistics (bytes/percentages).
 Return value: *Integer* - for bytes; *Float* - for percentage.

Parameters:

- **url** - the VMware service URL;
- **uuid** - the VMware virtual machine global unique identifier;
- **fsname** - the file system name;
- **mode** - *total*, *free*, *used*, *pfree*, or *pused*.

VMware Tools must be installed on the guest virtual machine for this item to work.

Footnotes

¹ See [Creating custom performance counter names for VMware](#).

² The value of these items is obtained from VMware performance counters and the `VMwarePerfFrequency` [parameter](#) is used to refresh their data in Zabbix VMware cache:

- vmware.cl.perfcounter
- vmware.hv.datastore.read
- vmware.hv.datastore.write
- vmware.hv.network.in
- vmware.hv.network.out

- vmware.hv.perfcounter
- vmware.vm.cpu.ready
- vmware.vm.net.if.in
- vmware.vm.net.if.out
- vmware.vm.perfcounter
- vmware.vm.vfs.dev.read
- vmware.vm.vfs.dev.write

More info

See [Virtual machine monitoring](#) for detailed information how to configure Zabbix to monitor VMware environments.

2 Virtual machine discovery key fields

The following table lists fields returned by virtual machine related discovery keys.

| Item key | | |
|-----------------------------------|---------------------|--|
| Description | Field | Retrieved content |
| vmware.cluster.discovery | | |
| Performs cluster discovery. | {#CLUSTER.ID} | Cluster identifier. |
| | {#CLUSTER.NAME} | Cluster name. |
| | "resource_pool" | An array containing resource pool data, including resource group ID, tags array, resource pool path, number of virtual machines. Array structure: [{"rp_id":"resource group id", "tags":[]}, "rpath":"resource group path", "vm_count":0] |
| | "tags" | For "tags" array structure, see the "tags" field. An array containing tags with tag name, description and category. Array structure: [{"tag":"tag name", "tag_description":"tag description", "category":"tag category" }] |
| vmware.datastore.discovery | | |
| Performs datastore discovery. | {#DATASTORE} | Datastore name. |
| | {#DATASTORE.EXTENT} | An array containing datastore extent partition ID and instance name. Array structure: [{"partitionid":1, "instance":"name" }] |
| | {#DATASTORE.TYPE} | Datastore type. |
| | | Value examples: VMFS, NFS, vsan, etc. |
| | {#DATASTORE.UUID} | Datastore identifier. |

Item key

| | | |
|--|--------------------|--|
| | "tags" | An array containing tags with tag name, description and category. Array structure: [{ "tag": "tag name", "tag_description": "tag description", "category": "tag category" }] |
| vmware.dc.discovery Performs datacenter discovery. | {#DATACENTER} | Datacenter name. |
| | {#DATACENTERID} | Datacenter identifier. |
| | "tags" | An array containing tags with tag name, description and category. Array structure: [{ "tag": "tag name", "tag_description": "tag description", "category": "tag category" }] |
| vmware.dvswitch.discovery Performs vSphere distributed switches discovery. | {#DVS.NAME} | Switch name. |
| | {#DVS.UUID} | Switch identifier. |
| vmware.hv.discovery Performs hypervisor discovery. | {#HV.UUID} | Unique hypervisor identifier. |
| | {#HV.ID} | Hypervisor identifier (HostSystem managed object name). |
| | {#HV.NAME} | Hypervisor name. |
| | {#HV.NETNAME} | Hypervisor network host name. |
| | {#HV.IP} | Hypervisor IP address, might be empty. |
| | | In case of an HA configuration with multiple net interfaces, the following selection priority for interface is observed: - prefer the IP which shares the IP-subnet with the vCenter IP; - prefer the IP from IP-subnet with default gateway; - prefer the IP from interface with the lowest ID. |
| | {#CLUSTER.NAME} | Cluster name, might be empty. |
| | {#DATACENTER.NAME} | Datacenter name. |
| | {#PARENT.NAME} | Name of container that stores the hypervisor. |
| | {#PARENT.TYPE} | Type of container in which the hypervisor is stored. The values could be Datacenter, Folder, ClusterComputeResource, VMware, where "VMware" stands for unknown container type. |
| | "resource_pool" | An array containing resource pool data, including resource group ID, tags array, resource pool path, number of virtual machines. Array structure: [{ "rpid": "resource group id", "tags": [{}], "rpath": "resource group path", "vm_count": 0 }] For "tags" array structure, see the "tags" field. |

Item key

| | | |
|---|------------------------------|--|
| | "tags" | An array containing tags with tag name, description and category. Array structure: [{"tag": "tag name", "tag_description": "tag description", "category": "tag category" }] |
| vmware.hv.datastore.discovery Performs hypervisor datastore discovery. Note that multiple hypervisors can use the same datastore. | {#DATASTORE} | Datastore name. |
| | {#DATASTORE.TYPE} | Datastore type. Value examples: VMFS, NFS, vsan, etc. |
| | {#DATASTORE.UUID} | Datastore identifier. |
| | {#MULTIPATH.COUNT} | Registered number of datastore paths. |
| | {#MULTIPATH.PARTITION.COUNT} | Number of available disk partitions. |
| | "datastore_extent" | An array containing datastore extent instance name and partition ID. Array structure: [{"partitionid": 1, "instance": "name" }] |
| | "tags" | An array containing tags with tag name, description and category. Array structure: [{"tag": "tag name", "tag_description": "tag description", "category": "tag category" }] |
| vmware.hv.net.if.discovery Performs hypervisor network interfaces discovery. | {#IFNAME} | Interface name. |
| | {#IFDRIVER} | Interface driver. |
| | {#IFDUPLEX} | Interface duplex settings. |
| | {#IFSPEED} | Interface speed. |
| | {#IFMAC} | Interface mac address. |
| vmware.vm.discovery Performs virtual machine discovery. | {#VM.UUID} | Unique virtual machine identifier. |
| | {#VM.ID} | Virtual machine identifier (VirtualMachine managed object name). |
| | {#VM.NAME} | Virtual machine name. |
| | {#HV.NAME} | Hypervisor name. |
| | {#HV.UUID} | Unique hypervisor identifier. |
| | {#HV.ID} | Hypervisor identifier (HostSystem managed object name). |
| | {#CLUSTER.NAME} | Cluster name, might be empty. |
| | {#DATACENTER.NAME} | Datacenter name. |
| | {#DATASTORE.NAME} | Datastore name. |
| | {#DATASTORE.UUID} | Datastore identifier. |
| | {#VM.IP} | Virtual machine IP address, might be empty. |
| | {#VM.DNS} | Virtual machine DNS name, might be empty. |
| | {#VM.GUESTFAMILY} | Guest virtual machine OS family, might be empty. |
| | {#VM.GUESTFULLNAME} | Full guest virtual machine OS name, might be empty. |
| | {#VM.FOLDER} | The chain of virtual machine parent folders, can be used as value for nested groups; folder names are combined with "/". Might be empty. |

Item key

| | |
|----------------------|--|
| {#VM.TOOLS.STATUS} | VMware virtual machine tools state. |
| {#VM.POWERSTATE} | VMware virtual machine power state (poweredOff, poweredOn, or suspended). |
| {#VM.RPOOL.ID} | Resource pool identifier. |
| {#VM.RPOOL.PATH} | Full resource pool path excluding the "root" name "Resources". Folder names are combined with "/". |
| {#VM.SNAPSHOT.COUNT} | Number of VM snapshots. |
| "tags" | An array containing tags with tag name, description and category. Array structure: [{ "tag": "tag name", "tag_description": "tag description", "category": "tag category" }] |
| "vm_customattribute" | An array of virtual machine custom attributes (if defined). Array structure: [{ "name": "custom field name", "value": "custom field value" }] |
| "net_if" | An array of virtual machine network interfaces. Array structure: [{ "ifname": "interface name", "ifdesc": "interface description", "ifmac": "00:00:00:00:00:00", "ifconnected": true, "iftype": "interface type", "ifbackingdevice": "interface backing device", "ifdvswitch_uuid": "interface switch uuid", "ifdvswitch_portgroup": "interface switch port group", "ifdvswitch_port": "interface switch port", "ifip": ["interface ip addresses"] }] |

For the description of returned data, see the
"vmware.vm.net.if.discovery" item key.

vmware.vm.net.if.discovery

Performs virtual
machine network
interface discovery.

| | |
|-------------------------|---|
| {#IFNAME} | Network interface name. |
| {#IFDESC} | Interface description. |
| {#IFMAC} | Interface mac address. |
| {#IFCONNECTED} | Interface connection status (false - disconnected; true - connected). |
| {#IFTYPE} | Interface type. |
| {#IFBACKINGDEVICE} | Name of the backing device. |
| {#IFDVSWITCH.UUID} | Unique vSphere Distributed Switch identifier. |
| {#IFDVSWITCH.PORTGROUP} | Distributed port group. |
| {#IFDVSWITCH.PORT} | vSphere Distributed Switch port. |
| "ifip" | An array of interface addresses. |

vmware.vm.vfs.dev.discovery

Performs virtual
machine disk device
discovery.

| | |
|-------------|-------------------|
| {#DISKNAME} | Disk device name. |
|-------------|-------------------|

vmware.vm.vfs.fs.discovery

| Item key | | |
|---|-----------|-------------------|
| Performs virtual machine file system discovery. | {#FSNAME} | File system name. |

3 JSON examples for VMware items

Overview This section provides additional information about JSON objects returned by various VMware [items](#).

vmware.*.alarms.get The items **vmware.alarms.get[]**, **vmware.cluster.alarms.get[]**, **vmware.datastore.alarms.get[]**, **vmware.dc.alarms.get[]**, **vmware.hv.alarms.get[]**, **vmware.vm.alarms.get[]** return JSON objects with the following structure (values are provided as an example):

```
{
  "alarms": [
    {
      "name": "Host connection and power state",
      "system_name": "alarm.HostConnectionStateAlarm",
      "description": "Default alarm to monitor host connection and power state",
      "enabled": true,
      "key": "alarm-1.host-2013",
      "time": "2022-06-27T05:27:38.759976Z",
      "overall_status": "red",
      "acknowledged": false
    },
    {
      "name": "Host memory usage",
      "system_name": "alarm.HostMemoryUsageAlarm",
      "description": "Default alarm to monitor host memory usage",
      "enabled": true,
      "key": "alarm-4.host-1004",
      "time": "2022-05-16T13:32:42.47863Z",
      "overall_status": "yellow",
      "acknowledged": false
    },
    {
      // other alarms
    }
  ]
}
```

vmware.*.tags.get The items **vmware.cluster.tags.get[]**, **vmware.datastore.tags.get[]**, **vmware.dc.tags.get[]**, **vmware.hv.tags.get[]**, **vmware.vm.tags.get[]** return JSON objects with the following structure (values are provided as an example):

```
{
  "tags": [
    {
      "name": "Windows",
      "description": "tag for cat OS type",
      "category": "OS type"
    },
    {
      "name": "SQL Server",
      "description": "tag for cat application name",
      "category": "application name"
    },
    {
      // other tags
    }
  ]
}
```

```

    }
  ]
}

```

vmware.hv.diskinfo.get The item **vmware.hv.diskinfo.get[]** returns JSON objects with the following structure (values are provided as an example):

```

[
  {
    "instance": "mpx.vmhba32:C0:T0:L0",
    "hv_uuid": "8002299e-d7b9-8728-d224-76004bbb6100",
    "datastore_uuid": "",
    "operational_state": [
      "ok"
    ],
    "lun_type": "disk",
    "queue_depth": 1,
    "model": "USB DISK",
    "vendor": "SMI Corp",
    "revision": "1100",
    "serial_number": "CCYYMMDDHHmmSS9S62CK",
    "vsan": {}
  },
  {
    // other instances
  }
]

```

vmware.dvswitch.fetchports.get The item **vmware.dvswitch.fetchports.get[]** returns JSON objects with the following structure (values are provided as an example):

```

{
  "FetchDVPortsResponse":
  {
    "returnval": [
      {
        "key": "0",
        "dvsUuid": "50 36 6a 24 25 c0 10 9e-05 4a f6 ea 4e 3d 09 88",
        "portgroupKey": "dvportgroup-2023",
        "proxyHost":
        {
          "@type": "HostSystem",
          "#text": "host-2021"
        },
        "connectee":
        {
          "connectedEntity":
          {
            "@type": "HostSystem",
            "#text": "host-2021"
          },
          "nicKey": "vmnic0",
          "type": "pnic"
        },
        "conflict": "false",
        "state":
        {
          "runtimeInfo":
          {
            "linkUp": "true",
            "blocked": "false",
            "vlanIds":
            {

```

```

        "start": "0",
        "end": "4094"
    },
    "trunkingMode": "true",
    "linkPeer": "vmmnic0",
    "macAddress": "00:00:00:00:00:00",
    "statusDetail": null,
    "vmDirectPathGen2Active": "false",
    "vmDirectPathGen2InactiveReasonOther": "portNptIncompatibleConnectee"
},
"stats":
{
    "packetsInMulticast": "2385470",
    "packetsOutMulticast": "45",
    "bytesInMulticast": "309250248",

vmware.hv.hw.sensors.get The item **vmware.hv.hw.sensors.get[]** returns JSON objects with the following structure (values are provided as an example):

```

{
    "val":
    {
        "@type": "HostHardwareStatusInfo",
        "storageStatusInfo": [
            {
                "name": "Intel Corporation HD Graphics 630 #2",
                "status":
                {
                    "label": "Unknown",
                    "summary": "Cannot report on the current status of the physical element",
                    "key": "Unknown"
                }
            },
            {
                "name": "Intel Corporation 200 Series/Z370 Chipset Family USB 3.0 xHCI Controller #20",
                "status":
                {
                    "label": "Unknown",

```

```

        "summary": "Cannot report on the current status of the physical element",
        "key": "Unknown"
    }
},
{
    // other hv hw sensors
}
]
}

```

vmware.hv.sensors.get The item **vmware.hv.sensors.get[]** returns JSON objects with the following structure (values are provided as an example):

```

{
    "val":
    {
        "@type": "ArrayOfHostNumericSensorInfo", "HostNumericSensorInfo": [
            {
                "@type": "HostNumericSensorInfo",
                "name": "System Board 1 PwrMeter Output --- Normal",
                "healthState":
                {
                    "label": "Green",
                    "summary": "Sensor is operating under normal conditions",
                    "key": "green"
                },
                "currentReading": "10500",
                "unitModifier": "-2",
                "baseUnits": "Watts",
                "sensorType": "other"
            },
            {
                "@type": "HostNumericSensorInfo",
                "name": "Power Supply 1 PS 1 Output --- Normal",
                "healthState":
                {
                    "label": "Green",
                    "summary": "Sensor is operating under normal conditions",
                    "key": "green"
                },
                "currentReading": "10000",
                "unitModifier": "-2",
                "baseUnits": "Watts",
                "sensorType": "power"
            },
            {
                // other hv sensors
            }
        ]
    }
}

```

vmware.vm.snapshot.get If any snapshots exist, the item **vmware.snapshot.get[]** returns a JSON object with the following structure (values are provided as an example):

```

{
    "snapshot": [
        {
            "name": "VM Snapshot 4%2f1%2f2022, 9:16:39 AM",
            "description": "Descr 1",
            "createtime": "2022-04-01T06:16:51.761Z",
            "size": 5755795171,

```

```

    "uniquesize": 5755795171
  },
  {
    "name": "VM Snapshot 4%2f1%2f2022, 9:18:21 AM",
    "description": "Descr 2",
    "createtime": "2022-04-01T06:18:29.164999Z",
    "size": 118650595,
    "uniquesize": 118650595
  },
  {
    "name": "VM Snapshot 4%2f1%2f2022, 9:37:29 AM",
    "description": "Descr 3",
    "createtime": "2022-04-01T06:37:53.534999Z",
    "size": 62935016,
    "uniquesize": 62935016
  }
],
"count": 3,
"latestdate": "2022-04-01T06:37:53.534999Z",
"lateststage": 22729203,

"oldeststage": 22730465,
"size": 5937380782,
"uniquesize": 5937380782
}

```

If no snapshot exists, the item **vmware.snapshot.get[]** returns a JSON object with empty values:

```

{
  "snapshot": [],
  "count": 0,
  "latestdate": null,
  "lateststage": 0,
  "oldestdate": null,
  "oldeststage": 0,
  "size": 0,
  "uniquesize": 0
}

```

4 VMware monitoring setup example

Overview

The following example describes how to set up Zabbix for monitoring VMware virtual machines. This involves:

- creating a host that represents your VMware environment;
- creating a low-level discovery rule that discovers virtual machines in your VMware environment;
- creating a host prototype, based on which Zabbix will generate real hosts for virtual machines discovered by the low-level discovery rule.

Prerequisites

Note:

This example does not cover the configuration of VMware. It is assumed that VMware is already configured.

Before proceeding, set the **StartVMwareCollectors** parameter in Zabbix server configuration file to 2 or more (the default value is 0).

Create a host

1. Go to *Data collection* → *Hosts*.
2. **Create** a host:

- In the *Host name* field, enter a host name (for example, "VMware VMs").
- In the *Host groups* field, type or select a host group (for example, "Virtual machines").

New host

Add Cancel

- In the *Macros* tab, set the following host macros:
 - {\$VMWARE.URL} - VMware service (ESXi hypervisor) SDK URL (https://servername/sdk)
 - {\$VMWARE.USERNAME} - VMware service user name
 - {\$VMWARE.PASSWORD} - VMware service {\$VMWARE.USERNAME} user password

New host

Host IPMI Tags **Macros 3** Inventory Encryption Value mapping

Host macros Inherited and host macros

| Macro | Value | Description |
|---------------------|------------------------|---------------------------------|
| {\$VMWARE.URL} | https://servername/sdk | description Remove |
| {\$VMWARE.USERNAME} | username | description Remove |
| {\$VMWARE.PASSWORD} | ***** | description Remove |

[Add](#)

Add Cancel

3. Click the *Add* button to create the host. This host will represent your VMware environment.

Create a low-level discovery rule

1. Click *Discovery* for the created host to go to the list of low-level discovery rules for that host.

2. **Create** a low-level discovery rule:

- In the *Name* field, enter a low-level discovery rule name (for example, "Discover VMware VMs").
- In the *Type* field, select "Simple check".
- In the *Key* field, enter the built-in item key for discovering VMware virtual machines: `vmware.vm.discovery[{$VMWARE.URL}]`
- In the *User name* and *Password* fields, enter the corresponding macros previously configured on the host.

3. Click the *Add* button to create the low-level discovery rule. This discovery rule will discover virtual machines in your VMware environment.

Create a host prototype

1. In the list of low-level discovery rules, click *Host prototypes* for the previously created low-level discovery rule.
2. **Create** a host prototype. Since host prototypes are blueprints for creating hosts through low-level discovery rules, most fields will contain **low-level discovery macros**. This ensures that the hosts are created with properties based on the **content retrieved** by the previously created low-level discovery rule.
 - In the *Host name* field, enter the macro `{#VM.UUID}`.
 - In the *Visible name* field, enter the macro `{#VM.NAME}`.
 - In the *Templates* field, enter or select the "VMware Guest" template. This template contains **VMware items** and discovery rules for monitoring the power state of a virtual machine, CPU usage, memory usage, network devices, etc.
 - In the *Host groups* field, enter or select a host group (for example, "Discovered hosts").
 - In the *Interfaces* field, add a custom **host interface**. Then, enter the macro `{#VM.DNS}` in the *DNS name* field, or enter the macro `{#VM.IP}` in the *IP address* field. Alternatively, if your VMware environment virtual machines have multiple interfaces, proceed to the **Advanced host interface configuration** section. Configuring a custom host interface is necessary for the correct functioning of the *VMware Guest* template.

| Agent | <input type="text"/> | <input type="text" value="{#VM.DNS}"/> | <input type="radio"/> IP <input checked="" type="radio"/> DNS | <input type="text" value="10050"/> | <input checked="" type="radio"/> <input type="button" value="Remove"/> |

Monitored by proxy

Create enabled ☒

Discover ☒

- In the *Macros* tab, set the `{ $VMWARE.VM.UUID }` macro with the value `{ #VM.UUID }`. This is necessary for the correct functioning of the *VMware Guest* template that uses this macro as a host-level user macro in item parameters (for example, `vmware.vm.net.if.discovery[{ $VMWARE.URL }, { $VMWARE.VM.UUID }]`).

Host IPMI Tags **Macros 1** Inventory Encryption

Host prototype macros

| Macro | Value |
|---|--|
| <input type="text" value="{ \$VMWARE.VM.UUID }"/> | <input type="text" value="{ #VM.UUID }"/> <input type="button" value="T v"/> |

3. Click the *Add* button to create the host prototype. This host prototype will be used to create hosts for virtual machines discovered by the previously created low-level discovery rule.

View hosts and metrics

After the host prototype has been created, the low-level discovery rule will create hosts for discovered VMware virtual machines, and Zabbix will start to monitor them. Note that the discovery and creation of hosts can also be **executed manually**, if necessary.

To view the created hosts, navigate to the *Data collection* → *Hosts* menu section.

≡ Hosts ?

Advanced host interface configuration

The `vmware.vm.discovery[{$VMWARE.URL}]` item key, configured in the *Create a low-level discovery rule* section, returns network interfaces data in the `"net_if"` field:

```
"net_if": [
  {
    "ifname": "5000",
    "ifdesc": "Network adapter 1",
    "ifmac": "00:11:22:33:44:55",
    "ifconnected": true,
    "iftype": "VirtualVmxnet3",
    "ifbackingdevice": "VLAN(myLab)",
    "ifdvswitch_uuid": "",
    "ifdvswitch_portgroup": "",
    "ifdvswitch_port": "",
    "ifip": [
      "127.0.0.1",
      "::1"
    ]
  },
  {
    "ifname": "5001",
    "ifdesc": "Network adapter 2",
    "ifmac": "00:11:22:33:44:55",
    "ifconnected": false,
    "iftype": "VirtualVmxnet3",
    "ifbackingdevice": "VLAN(myLab2)",
    "ifdvswitch_uuid": "",
    "ifdvswitch_portgroup": "",
    "ifdvswitch_port": "",
    "ifip": []
  }
]
```

This data can be used to configure a custom host interface.

1. When *creating a low-level discovery rule*, additionally configure a *low-level discovery macro*. In the *LLD macros* tab, create a custom LLD macro with a *JSONPath* value. For example:

- `{#MYLAB.NET.IF} - $.net_if[?(@.ifbackingdevice=="VLAN(myLab)")].ifip[0].first()`

| | | | | |
|----------------------------|---------------|---|---------|-----------|
| Discovery rule | Preprocessing | LLD macros 1 | Filters | Overrides |
| LLD macros | | | | |
| LLD macro | | JSONPath | | |
| <div>{#MYLAB.NET.IF}</div> | | <div>\$.net_if[?(@.ifbackingdevice=="VLAN(myLab)")].ifip[0].first()</div> | | |
| <div>Add</div> | | <div>Remove</div> | | |
| <div>Add</div> | | | | |
| <div>Test</div> | | | | |
| <div>Cancel</div> | | | | |

2. When *creating a host prototype*, add a custom host interface and enter the LLD macro in the *DNS name* or *IP address* field.

11 Maintenance

Overview You can define maintenance periods for hosts and host groups in Zabbix.

Furthermore, it is possible to define maintenance only for a single trigger (or subset of triggers) by specifying trigger tags. In this case maintenance will be activated only for those triggers; all other triggers of the host or host group will not be in maintenance.

There are two maintenance types - with data collection and with no data collection.

During a maintenance “with data collection” triggers are processed as usual and events are created when required. However, problem escalations are paused for hosts/triggers in maintenance, if the *Pause operations for suppressed problems* option is checked in action configuration. In this case, escalation steps that may include sending notifications or remote commands will be ignored for as long as the maintenance period lasts. Note that problem recovery and update operations are not suppressed during maintenance, only escalations.

For example, if escalation steps are scheduled at 0, 30 and 60 minutes after a problem start, and there is a half-hour long maintenance lasting from 10 minutes to 40 minutes after a real problem arises, steps two and three will be executed a half-hour later, or at 60 minutes and 90 minutes (providing the problem still exists). Similarly, if a problem arises during the maintenance, the escalation will start after the maintenance.

To receive problem notifications during the maintenance normally (without delay), you have to uncheck the *Pause operations for suppressed problems* option in action configuration.

Note:

If at least one host (used in the trigger expression) is not in maintenance mode, Zabbix will send a problem notification.

Zabbix server must be running during maintenance. Maintenances are recalculated every minute or as soon as the configuration cache is reloaded if there are changes to the maintenance period.

Timer processes check if host status must be changed to/from maintenance at 0 seconds of every minute. Additionally, every second the timer process checks if any maintenances must be started/stopped based on whether there are changes to the **maintenance periods** after the configuration update. Thus the speed of starting/stopping maintenance periods depends on the configuration **update interval** (10 seconds by default). Note that maintenance period changes do not include *Active since/Active till* settings. Also, if a host/host group is added to an existing active maintenance period, the changes will only be activated by the timer process at the start of next minute.

Note that when a host enters maintenance, Zabbix server timer processes will read all open problems to check if it is required to suppress those. This may have a performance impact if there are many open problems. Zabbix server will also read all open problems upon startup, even if there are no maintenances configured at the time.

If maintenance period, hosts, groups or tags are changed by the user, the changes will only take effect after configuration cache synchronization.

1. Go to: *Data collection* → *Maintenance*.
2. Click on *Create maintenance period* (or on the name of an existing maintenance period).
3. Enter maintenance parameters in the form.

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|-------------|---------------------------------|
| <i>Name</i> | Name of the maintenance period. |

| Parameter | Description |
|-------------------------|--|
| <i>Maintenance type</i> | Two types of maintenance can be set: With data collection - data will be collected by the server during maintenance, triggers will be processed; No data collection - data will not be collected by the server during maintenance. |
| <i>Active since</i> | The date and time when executing maintenance periods becomes active. <i>Note:</i> Setting this time alone does not activate a maintenance period; maintenance periods must be configured in <i>Periods</i> (see below). |
| <i>Active till</i> | The date and time when executing maintenance periods stops being active. |
| <i>Periods</i> | This block allows you to define the exact days and hours when the maintenance takes place. Clicking on Add opens a popup window with a flexible <i>Maintenance period</i> form where you can define maintenance schedule. See Maintenance periods for a detailed description. |
| <i>Host groups</i> | Select host groups that the maintenance will be activated for. The maintenance will be activated for all hosts from the specified host group(s). This field is auto-complete, so starting to type in it will display a dropdown of all available host groups. Specifying a parent host group implicitly selects all nested host groups. Thus the maintenance will also be activated on hosts from nested groups. |
| <i>Hosts</i> | Select hosts that the maintenance will be activated for. This field is auto-complete, so starting to type in it will display a dropdown of all available hosts. |
| <i>Tags</i> | If maintenance tags are specified, maintenance for the selected hosts will be activated, but only problems with matching tags will be suppressed (that is, no actions will be taken). In case of multiple tags, they are calculated as follows: And/Or - all tags must correspond; however tags with the same tag name are calculated by the Or condition; Or - enough if one tag corresponds. There are two ways of matching the tag value: Contains - case-sensitive substring match (tag value contains the entered string); Equals - case-sensitive string match (tag value equals the entered string). Tags can be specified only if <i>With data collection</i> mode is selected. |
| <i>Description</i> | Description of maintenance period. |

Maintenance periods

The maintenance period window is for scheduling time for a recurring or a one-time maintenance. The form is dynamic with available fields changing based on the *Period type* selected.

| Period type | Description |
|----------------------|--|
| <i>One time only</i> | <p>Configure a one time only maintenance period:</p> <p><i>Date</i> - date and time of the maintenance period;</p> <p><i>Maintenance period length</i> - for how long the maintenance will be active.</p> |
| <i>Daily</i> | <p>Configure a daily maintenance period:</p> <p><i>Every day(s)</i> - maintenance frequency (1 - (<i>default</i>) every day, 2 - every two days, etc.);</p> <p><i>At (hour:minute)</i> - time of the day when maintenance starts;</p> <p><i>Maintenance period length</i> - for how long the maintenance will be active.</p> <p>When <i>Every day(s)</i> parameter is greater than "1", the starting day is the day that the <i>Active since</i> time falls on. Examples:</p> <ul style="list-style-type: none"> - if <i>Active since</i> is set to "2021-01-01 12:00", <i>Every day(s)</i> is set to "2", and <i>At (hour:minute)</i> is set to "23:00", then the first maintenance period will start on January 1 at 23:00, while the second maintenance period will start on January 3 at 23:00; - if <i>Active since</i> is set to "2021-01-01 12:00", <i>Every day(s)</i> is set to "2", and <i>At (hour:minute)</i> is set to "01:00", then the first maintenance period will start on January 3 at 01:00, while the second maintenance period will start on January 5 at 01:00. |
| <i>Weekly</i> | <p>Configure a weekly maintenance period:</p> <p><i>Every week(s)</i> - maintenance frequency (1 - (<i>default</i>) every week, 2 - every two weeks, etc.);</p> <p><i>Day of week</i> - on which day the maintenance should take place;</p> <p><i>At (hour:minute)</i> - time of the day when maintenance starts;</p> <p><i>Maintenance period length</i> - for how long the maintenance will be active.</p> <p>When <i>Every week(s)</i> parameter is greater than "1", the starting week is the week that the <i>Active since</i> time falls on. For examples, see parameter <i>Daily</i> description above.</p> |
| <i>Monthly</i> | <p>Configure a monthly maintenance period:</p> <p><i>Month</i> - select all months during which the regular maintenance is carried out;</p> <p><i>Date: Day of month</i> - select this option if the maintenance should take place on the same date each month (for example, every 1st day of the month), and then select the required day in the field <i>Day of month</i> that appears;</p> <p><i>Date: Day of week</i> - select this option if the maintenance should take place only on certain days (for example, every first Monday of the month), then select (in the drop-down) the required week of the month (first, second, third, fourth, or last), and then mark the checkboxes for maintenance day(s);</p> <p><i>At (hour:minute)</i> - time of the day when maintenance starts;</p> <p><i>Maintenance period length</i> - for how long the maintenance will be active.</p> |

Attention:

When creating a maintenance period, the **time zone** of the user who creates it is used. However, when recurring maintenance periods (*Daily*, *Weekly*, *Monthly*) are scheduled, the time zone of the Zabbix server is used. To ensure predictable behavior of recurring maintenance periods, it is required to use a common time zone for all parts of Zabbix.

When done, press *Add* to add the maintenance period to the *Periods* block.

Note that Daylight Saving Time (DST) changes do not affect how long the maintenance will be. For example, let's say that we have a two-hour maintenance configured that usually starts at 01:00 and finishes at 03:00:

- if after one hour of maintenance (at 02:00) a DST change happens and current time changes from 02:00 to 03:00, the maintenance will continue for one more hour (till 04:00);
- if after two hours of maintenance (at 03:00) a DST change happens and current time changes from 03:00 to 02:00, the maintenance will stop, because two hours have passed;
- if a maintenance period starts during the hour that is skipped by a DST change, then the maintenance will not start.

If a maintenance period is set to "1 day" (the actual period of the maintenance is 24 hours, since Zabbix calculates days in hours), starts at 00:00 and finishes at 00:00 the next day:

- the maintenance will stop at 01:00 the next day if current time changes forward one hour;
- the maintenance will stop at 23:00 that day if current time changes back one hour.

Display Displaying hosts in maintenance

An orange wrench icon  next to the host name indicates that this host is in maintenance in:

- *Dashboards*
- *Monitoring → Problems*
- *Inventory → Hosts → Host inventory details*
- *Data collection → Hosts* (See 'Status' column)

Maintenance details are displayed when the mouse pointer is positioned over the icon.

Additionally, hosts in maintenance get an orange background in *Monitoring → Maps*.

Displaying suppressed problems

Normally problems for hosts in maintenance are suppressed, i.e. not displayed in the frontend. However, it is also possible to configure that suppressed problems are shown, by selecting the *Show suppressed problems* option in these locations:

- *Dashboards* (in *Problem hosts*, *Problems*, *Problems by severity*, *Trigger overview* widget configuration)
- *Monitoring → Problems* (in the filter)
- *Monitoring → Maps* (in map configuration)
- Global **notifications** (in user profile configuration)

When suppressed problems are displayed, the following icon is displayed: . Rolling a mouse over the icon displays more details.

Calculation of queues during maintenance Queues displayed in the Zabbix frontend (*Administration > Queue*) are calculated by the Zabbix server. They do not include items under maintenance with no data collection—queue length is always zero for these items even when their values are delayed. Delayed items in maintenance with data collection are still counted in the queue.

The Zabbix **proxy** is not aware of maintenance periods because there is no synchronization of maintenance configuration between the Zabbix server and proxy. Internal checks calculated on Zabbix proxies (for example, `zabbix[queue,,]` and `zabbix[stats,,queue,,]`) report delayed items regardless of the maintenance status on the Zabbix server.

As a result, different queue lengths may be reported for the same items in maintenance with no data collection by the Zabbix frontend and by internal checks on Zabbix proxies.

12 Regular expressions

Overview [Perl Compatible Regular Expressions](#) (PCRE, PCRE2) are supported in Zabbix.

There are two ways of using regular expressions in Zabbix:

- manually entering a regular expression
- using a global regular expression created in Zabbix

Regular expressions You may manually enter a regular expression in supported places. Note that the expression may not start with `@` because that symbol is used in Zabbix for referencing global regular expressions.

Warning:

It's possible to run out of stack when using regular expressions. See the [pcrestack man page](#) for more information.

Note that in multiline matching, the ^ and \$ anchors match at the beginning/end of each line respectively, instead of the beginning/end of the entire string.

See also examples for **correct escaping** in various contexts.

Global regular expressions There is an advanced editor for creating and testing complex regular expressions in Zabbix frontend.

Once a regular expression has been created this way, it can be used in several places in the frontend by referring to its name, prefixed with @, for example, @mycustomregexp.

To create a global regular expression:

- Go to: Administration → General
- Select Regular expressions from the dropdown
- Click on New regular expression

The **Expressions** tab allows to set the regular expression name and add subexpressions.

ExpressionsTest

* Name

Network interfaces for discovery

* Expressions

| Expression type | Expression | Delimiter | Case s |
|-----------------|--------------------------------|-----------|-------------------------------------|
| Result is FALSE | ^Software Loopback Interface | | <input checked="" type="checkbox"/> |
| Result is FALSE | ^(In)?[Ll]oop[Bb]ack[0-9._]*\$ | | <input checked="" type="checkbox"/> |
| Result is FALSE | ^NULL[0-9.]*\$ | | <input checked="" type="checkbox"/> |
| Result is FALSE | ^[Ll]o[0-9.]*\$ | | <input checked="" type="checkbox"/> |
| Result is FALSE | ^[Ss]ystem\$ | | <input checked="" type="checkbox"/> |
| Result is FALSE | ^Nu[0-9.]*\$ | | <input checked="" type="checkbox"/> |

Add

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|-----------------|---|
| Name | Set the regular expression name. Any Unicode characters are allowed. |
| Expressions | Click on Add in the Expressions block to add a new subexpression. |
| Expression type | Select expression type: Character string included - match the substring Any character string included - match any substring from a delimited list. The delimited list includes a comma (,), a dot (.) or a forward slash (/). Character string not included - match any string except the substring Result is TRUE - match the regular expression Result is FALSE - do not match the regular expression |
| Expression | Enter substring/regular expression. |
| Delimiter | A comma (,), a dot (.) or a forward slash (/) to separate text strings in a regular expression. This parameter is active only when "Any character string included" expression type is selected. |
| Case sensitive | A checkbox to specify whether a regular expression is sensitive to capitalization of letters. |

A forward slash (/) in the expression is treated literally, rather than a delimiter. This way it is possible to save expressions containing a slash, without errors.

Attention:

A custom regular expression name in Zabbix may contain commas, spaces, etc. In those cases where that may lead to misinterpretation when referencing (for example, a comma in the parameter of an item key) the whole reference may be put in quotes like this: `"@My custom regexp for purpose1, purpose2"`.

Regular expression names must not be quoted in other locations (for example, in LLD rule properties).

In the **Test** tab the regular expression and its subexpressions can be tested by providing a test string.

ExpressionsTest

Test string

lo

Test expressions

Result

| Expression type | Expression | Result |
|-----------------|---|--------|
| Result is FALSE | <code>^Software Loopback Interface</code> | TRUE |
| Result is FALSE | <code>^(In)?[Ll]oop[Bb]ack[0-9._]*\$</code> | TRUE |
| Result is FALSE | <code>^NULL[0-9.]*\$</code> | TRUE |
| Result is FALSE | <code>^[Ll]o[0-9.]*\$</code> | FALSE |
| Result is FALSE | <code>^[Ss]ystem\$</code> | TRUE |
| Result is FALSE | <code>^Nu[0-9.]*\$</code> | TRUE |
| Combined result | | FALSE |

Results show the status of each subexpression and total custom expression status.

Total custom expression status is defined as *Combined result*. If several sub expressions are defined Zabbix uses AND logical operator to calculate *Combined result*. It means that if at least one Result is False *Combined result* has also False status.

Default global regular expressions Zabbix comes with several global regular expression in its default dataset.

| Name | Expression | Matches |
|----------------------------------|--|---|
| File systems for discovery | <code>^(btrfs ext2 ext3 ext4 jfs reiser xfs ffs ufs jfs2 vxfs hfs refs apfs ntfs fat32 zfs)\$</code> | Strings starting with "btrfs" or "ext2" or "ext3" or "ext4" or "jfs" or "reiser" or "xfs" or "ffs" or "ufs" or "jfs" or "jfs2" or "vxfs" or "hfs" or "refs" or "apfs" or "ntfs" or "fat32" or "zfs" |
| Network interfaces for discovery | <code>^Software Loopback Interface</code> | Strings starting with "Software Loopback Interface". |
| | <code>^lo\$</code> | "lo" |
| | <code>^(In)?[Ll]oop[Bb]ack[0-9._]*\$</code> | Strings that optionally start with "In", then have "L" or "l", then "oop", then "B" or "b", then "ack", which can be optionally followed by any number of digits, dots or underscores. |
| | <code>^NULL[0-9.]*\$</code> | Strings starting with "NULL" optionally followed by any number of digits or dots. |
| | <code>^[Ll]o[0-9.]*\$</code> | Strings starting with "Lo" or "lo" and optionally followed by any number of digits or dots. |
| | <code>^[Ss]ystem\$</code> | "System" or "system" |

| Name | Expression | Matches |
|---|--|--|
| | <code>^Nu[0-9.]*\$</code> | Strings starting with "Nu" optionally followed by any number of digits or dots. |
| <i>Storage devices for SNMP discovery</i> | <code>^(Physical memory Virtual memory Memory buffers Cached memory Swap space)\$</code> | "Physical memory" or "Virtual memory" or "Memory buffers" or "Cached memory" or "Swap space" |
| <i>Windows service names for discovery</i> | <code>^(MMCSS gupdate SysmonLog clr_optimization_v2.0.50727_32 CLR_SysmonLog CLR_SysmonLog_v4.0.30319_32)\$</code> | Strings like "CLR_SysmonLog_v4.0.30319_32" where instead of dots you can put any character except newline. |
| <i>Windows service startup states for discovery</i> | <code>^(automatic automatic delayed)\$</code> | "automatic" or "automatic delayed" |

Examples Example 1

Use of the following expression in low-level discovery to discover databases except a database with a specific name:

`^TESTDATABASE$`

Test string

TESTDATABASE

Test expressions

Result

Expression type

Result is FALSE

Combined result

Expression

`^TESTDATABASE`

Result

FALSE

FALSE

Chosen *Expression type*: "Result is FALSE". Doesn't match name, containing string "TESTDATABASE".

Example with an inline regex modifier

Use of the following regular expression including an inline modifier (?i) to match the characters "error":

`(?i)error`

Test string

Sometexthere1345Error1357

Test expressions

Result

Expression type

Result is TRUE

Combined result

Expression

`(?i)error`

Result

TRUE

TRUE

Chosen Expression type: "Result is TRUE". Characters "error" are matched.

Another example with an inline regex modifier

Use of the following regular expression including multiple inline modifiers to match the characters after a specific line:

(?<=match (?i)everything(?-i) after this line\n)(?sx).*# we add s modifier to allow . match newline character

Test string

Some text here for your consideration
1235kfd345
match eveRything after this line
Continuation

Test expressions

Result

| Expression type | Expression | Result |
|-----------------|--|--------|
| Result is TRUE | (?<=match (?i)everything(?-i) after this line\n)(?sx).*# we add s modifier to allow . match newline characters | TRUE |
| Combined result | | TRUE |

Chosen Expression type: "Result is TRUE". Characters after a specific line are matched.

Attention:

g modifier can't be specified in line. The list of available modifiers can be found in [pcre syntax man page](#). For more information about PCRE syntax please refer to [PCRE HTML documentation](#).

Regular expression support by location

| Location | Regular expression | Global regular expression | Multiline matching | Comments |
|--------------------------|--------------------|---------------------------|--------------------|--|
| Agent items | | | | |
| eventlog[] | Yes | Yes | Yes | regex, severity, source, eventid parameters |
| eventlog.count[] | | | | regex, severity, source, eventid parameters |
| log[] | | | | regex parameter |
| log.count[] | | | | |
| logrt[] | | Yes/No | | regex parameter supports both, file_regex parameter supports non-global expressions only |
| logrt.count[] | | | | |
| proc.cpu.util[] | | No | No | cmdline parameter |
| proc.get[] | | | | |
| proc.mem[] | | | | |
| proc.num[] | | | | |
| sensor[] | | | | device and sensor parameters on Linux 2.4 |
| system.hw.macaddr[] | | | | interface parameter |
| system.sw.packages[] | | | | regex parameter |
| system.sw.packages.get[] | | | | regex parameter |
| vfs.dir.count[] | | | | regex_incl, regex_excl, regex_excl_dir parameters |
| vfs.dir.get[] | | | | regex_incl, regex_excl, regex_excl_dir parameters |
| vfs.dir.size[] | | | | regex_incl, regex_excl, regex_excl_dir parameters |
| vfs.file.regex[] | | | Yes | regex parameter |
| vfs.file.regmatch[] | | | | |
| web.page.regex[] | | | | |

SNMP traps

| Location | Regular expression | Global regular expression | Multiline matching | Comments |
|--|--------------------|---------------------------|--------------------|--|
| snmptrap[] | Yes | Yes | No | regexp parameter |
| Item value pre-processing Functions for triggers/calculated items | Yes | No | No | pattern parameter |
| count() | Yes | Yes | Yes | pattern parameter if operator parameter is <i>regexp</i> or <i>iregexp</i> |
| countunique() | Yes | Yes | | |
| find() | Yes | Yes | | |
| logeventid() | Yes | Yes | No | pattern parameter |
| logsource() | | | | |
| Low-level discovery | | | | |
| Filters | Yes | Yes | No | <i>Regular expression</i> field |
| Overrides | Yes | No | | In <i>matches</i> , does not match options for <i>Operation</i> conditions |
| Action conditions | Yes | No | No | In <i>matches</i> , does not match options for <i>Host name</i> and <i>Host metadata</i> autoregistration conditions |
| Scripts | Yes | Yes | No | <i>Input validation rule</i> field |
| Web monitoring | Yes | No | Yes | Variables with a regex: prefix <i>Required string</i> field |
| User macro context Macro functions | Yes | No | No | In macro context with a regex: prefix |
| regsub() | Yes | No | No | pattern parameter |
| iregsub() | | | | |
| Icon mapping | Yes | Yes | No | <i>Expression</i> field |
| Value mapping | Yes | No | No | <i>Value</i> field if mapping type is <i>regexp</i> |

13 Problem acknowledgment

Overview Problem events in Zabbix can be acknowledged by users.

If a user gets notified about a problem event, they can go to Zabbix frontend, open the problem update popup window of that problem using one of the ways listed below and acknowledge the problem. When acknowledging, they can enter their comment

for it, saying that they are working on it or whatever else they may feel like saying about it.

This way, if another system user spots the same problem, they immediately see if it has been acknowledged and the comments so far.

This way the workflow of resolving problems with more than one system user can take place in a coordinated way.

Acknowledgment status is also used when defining **action operations**. You can define, for example, that a notification is sent to a higher level manager only if an event is not acknowledged for some time.

To acknowledge events and comment on them, a user must have at least read permissions to the corresponding triggers. To change problem severity or close problem, a user must have read-write permissions to the corresponding triggers.

There are **several** ways to access the problem update popup window, which allows acknowledging a problem.

- You may select problems in *Monitoring → Problems* and then click on *Mass update* below the list
- You can click on *Update* in the *Update* column of a problem in:
 - *Dashboards (Problems and Problems by severity* widgets)
 - *Monitoring → Problems*
 - *Monitoring → Problems → Event details*
- You can click on an unresolved problem cell in:
 - *Dashboards (Trigger overview* widget)

The popup menu contains an *Update* option that will take you to the problem update window.

Updating problems The problem update popup allows to:

- comment on the problem
- view comments and actions so far
- change problem severity
- suppress/unsuppress problem
- acknowledge/unacknowledge problem
- change symptom problem to cause problem
- manually close problem

Update problem?×

Problem */*: Disk space is critically low (used > 90%)

Update

Cancel

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|------------------------|---|
| <i>Problem</i> | If only one problem is selected, the problem name is displayed. If several problems are selected, <i>N problems selected</i> is displayed. |
| <i>Message</i> | Enter text to comment on the problem (maximum 2048 characters). |
| <i>History</i> | Previous activities and comments on the problem are listed, along with the time and user details. For the meaning of icons used to denote user actions see the event detail page. Note that history is displayed if only one problem is selected for the update. |
| <i>Scope</i> | Define the scope of such actions as changing severity, acknowledging or manually closing problems: Only selected problem - will affect this event only Selected and all other problems of related triggers - in case of acknowledgment/closing problem, will affect this event and all other problems that are not acknowledged/closed so far. If the scope contains problems already acknowledged or closed, these problems will not be acknowledged/closed repeatedly. On the other hand, the number of message and severity change operations are not limited. |
| <i>Change severity</i> | Mark the checkbox and click on the severity button to update problem severity. The checkbox for changing severity is available if read-write permissions exist for at least one of the selected problems. Only those problems that are read-writable will be updated when clicking on <i>Update</i> . If read-write permissions exist for none of the selected triggers, the checkbox is disabled. |

| Parameter | Description |
|-------------------------|---|
| <i>Suppress</i> | <p>Mark the checkbox to suppress the problem:</p> <p>Indefinitely - suppress indefinitely</p> <p>Until - suppress until a given time. Both absolute and relative time formats are supported, for example:</p> <p><code>now+1d</code> - for one day from now (default)</p> <p><code>now/w</code> - until the end of the current week</p> <p><code>2022-05-28 12:00:00</code> - until absolute date/time</p> <p>Note that a simple period (e. g., <code>1d</code>, <code>1w</code>) is not supported.</p> <p>Availability of this option depends on the "Suppress problems" user role settings.</p> <p>See also: Problem suppression</p> |
| <i>Unsuppress</i> | <p>Mark the checkbox to unsuppress the problem. This checkbox is active only if at least one of the selected problems is suppressed.</p> <p>Availability of this option depends on the "Suppress problems" user role settings.</p> |
| <i>Acknowledge</i> | <p>Mark the checkbox to acknowledge the problem.</p> <p>This checkbox is available if there is at least one unacknowledged problem among the selected. It is not possible to add another acknowledgment for an already acknowledged problem (it is possible to add another comment though).</p> |
| <i>Unacknowledge</i> | <p>Mark the checkbox to unacknowledge the problem.</p> <p>This checkbox is available if there is at least one acknowledged problem among the selected.</p> |
| <i>Convert to cause</i> | <p>Mark the checkbox to convert the symptom problem(s) to cause problem(s).</p> |
| <i>Close problem</i> | <p>Mark the checkbox to manually close the selected problem(s).</p> <p>The checkbox for closing a problem is available if the <i>Allow manual close</i> option is checked in trigger configuration for at least one of the selected problems. Only those problems will be closed that are allowed to be closed when clicking on <i>Update</i>.</p> <p>If no problem is manually closeable, the checkbox is disabled.</p> <p>Already closed problems will not be closed repeatedly.</p> |

Display Based on acknowledgment information it is possible to configure how the problem count is displayed in the dashboard or maps. To do that, you have to make selections in the *Problem display* option, available in both **map configuration** and the *Problems by severity dashboard widget*. It is possible to display all problem count, unacknowledged problem count as separated from the total or unacknowledged problem count only.

Based on problem update information (acknowledgment, etc.), it is possible to configure update operations - send a message or execute remote commands.

1 Problem suppression

Overview

Problem suppression offers a way of temporarily hiding a problem that can be dealt with later. This is useful for cleaning up the problem list in order to give the highest priority to the most urgent issues. For example, sometimes an issue may arise on the weekend that is not urgent enough to be dealt with immediately, so it can be "snoozed" until Monday morning.

Problem suppression allows to hide a *single* problem, in contrast to problem suppression through host maintenance when all problems of the maintenance host are hidden.

Operations for trigger actions will be paused for suppressed problems the same way as it is done with **host maintenance**.

Configuration

A problem can be suppressed through the **problem update** window, where suppression is one of the problem update options along with commenting, changing severity, acknowledging, etc.

A problem may also be unsuppressed through the same problem update window.

Display

Once suppressed the problem is marked by a blinking  suppression icon in the *Info* column, before being hidden.

The suppression icon is blinking while the suppression task is in the waiting list. Once the task manager has suppressed the problem, the icon will stop blinking. If the suppression icon keeps blinking for a long time, this may indicate a server problem, for example, if the server is down and the task manager cannot complete the task. The same logic applies to unsuppression. In the short period after the task is submitted and the server has not completed it, the unsuppression icon is blinking.

A suppressed problem may be both hidden or shown, depending on the problem filter/widget settings.

When shown in the problem list, a suppressed problem is marked by the suppression icon and suppression details are shown on mouseover:

| Current problems | | | | | | |
|---------------------|---|--------|--|-------------|-----|---|
| Time ▼ | Info | Host | Problem • Severity | Duration | Ack | Action |
| 2022-06-09 13:11:16 |  | Zabbix | /: Disk space is critically low (used > 90%) | 22h 38m 14s | No |  |
| 2022-06-09 11:56:31 | Suppressed till: 12:04 Manually by: Admin (Zabbix Administrator) | | | 23h 52m 59s | No | |

Suppression details are also displayed in a popup when positioning the mouse on the suppression icon in the *Actions* column.

14 Configuration export/import

Overview Zabbix export/import functionality makes it possible to exchange various configuration entities between one Zabbix system and another.

Typical use cases for this functionality:

- share templates or network maps - Zabbix users may share their configuration parameters
- upload a template to [Zabbix Community templates](#). Then others can download the template and import the file into Zabbix.
- integrate with third-party tools - universal YAML, XML and JSON formats make integration and data import/export possible with third-party tools and applications

What can be exported/imported

Objects that can be exported/imported are:

- **Host groups** (through Zabbix API only)
- **Template groups** (through Zabbix API only)
- **Templates**
- **Hosts**
- **Network maps**
- **Media types**
- **Images**

Export format

Data can be exported using the Zabbix web frontend or [Zabbix API](#). Supported export formats are YAML, XML and JSON.

Details about export

- All supported elements are exported in one file.
- Host and template entities (items, triggers, graphs, discovery rules) that are inherited from linked templates are not exported. Any changes made to those entities on a host level (such as changed item interval, modified regular expression or added prototypes to the low-level discovery rule) will be lost when exporting; when importing, all entities from linked templates are re-created as on the original linked template.
- Entities created by low-level discovery and any entities depending on them are not exported. For example, a trigger created for an LLD-rule generated item will not be exported.
- When the exported host/template contains entities supporting timeouts, the timeout values will be exported if these entities have their own timeouts configured.

Details about import

- Import stops at the first error.
- When updating existing images during image import, "imagetype" field is ignored, i.e., it is impossible to change image type via import.

- When importing hosts/templates using the "Delete missing" option, host/template macros not present in the import file will be deleted from the host/template after the import.
- Empty tags for items, triggers, graphs, discoveryRules, itemPrototypes, triggerPrototypes, graphPrototypes are meaningless, i.e., it's the same as if it was missing.
- If entities of the imported host/template have their own timeouts configured, they will be applied; otherwise, proxy/global timeouts will be applied.
- Import supports YAML, XML and JSON, the import file must have a correct file extension: .yaml and .yml for YAML, .xml for XML and .json for JSON. See [compatibility information](#) about supported XML versions.
- Import supports configuration files only in UTF-8 encoding (with or without [BOM](#)); other encodings (UTF16LE, UTF16BE, UTF32LE, UTF32BE, etc.) will result in an import conversion error.

YAML base format The YAML export format contains the following nodes:

- Root node for Zabbix YAML export
- Export version

```
zabbix_export:
  version: '7.2'
```

Other nodes are dependent on exported objects.

XML format The XML export format contains the following tags:

- Default header for XML documents
- Root tag for Zabbix XML export
- Export version

```
<?xml version="1.0" encoding="UTF-8"?>
<zabbix_export>
  <version>7.2</version>
</zabbix_export>
```

Other tags are dependent on exported objects.

JSON format The JSON export format contains the following objects:

- Root object for Zabbix JSON export
- Export version

```
{
  "zabbix_export": {
    "version": "7.2"
  }
}
```

Other objects are dependent on exported objects.

1 Template groups

Overview

In the frontend, template groups can be **exported** only with template export. When a template is exported, all groups it belongs to are exported with it automatically.

API allows exporting template groups independently of templates.

Export format

```
template_groups:
- uuid: 36bff6c29af64692839d077febf7079
  name: 'Network devices'
```

Exported elements

| Element | Type | Description |
|---------|--------|--|
| uuid | string | Unique identifier for this template group. |
| name | string | Group name. |

2 Host groups

Overview

In the frontend, host groups can be **exported** only with host export. When a host is exported, all groups it belongs to are exported with it automatically.

API allows exporting host groups independently of hosts.

Export format

```
host_groups:
- uuid: 6f6799aa69e844b4b3918f779f2abf08
  name: 'Zabbix servers'
```

Exported elements

| Element | Type | Description |
|---------|--------|--|
| uuid | string | Unique identifier for this host group. |
| name | string | Group name. |

3 Templates

Overview

Templates are **exported** with many related objects and object relations.

Template export contains:

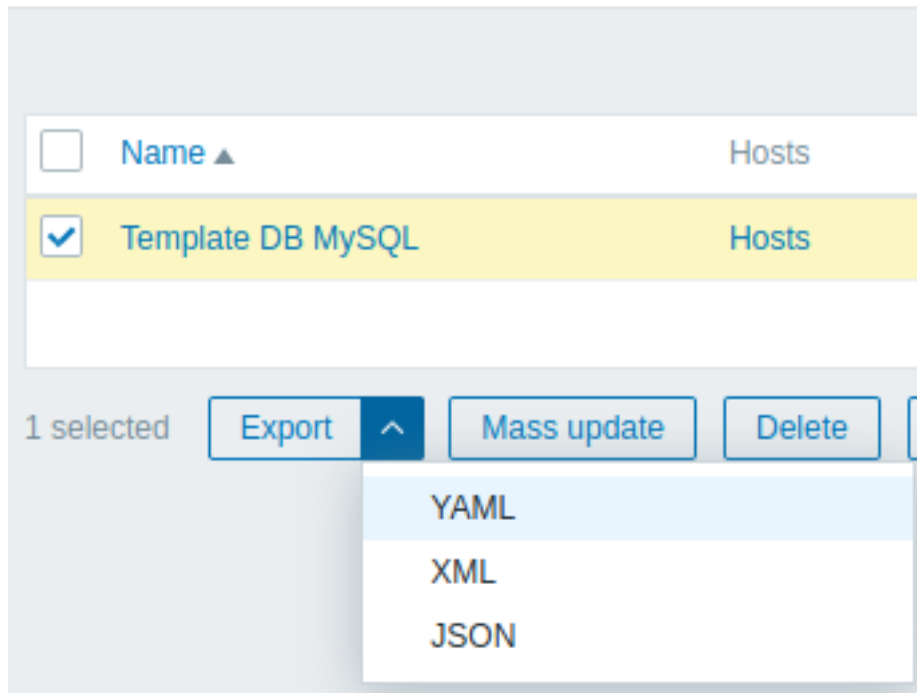

- Linked template groups
- Linked host groups (if used in **host prototype** configuration)
- Template data
- Linkage to other templates
- Linkage to template groups
- Directly linked items
- Directly linked triggers
- Directly linked graphs
- Directly linked dashboards
- Directly linked discovery rules with all prototypes
- Directly linked web scenarios
- Value maps

Exporting

To export templates, do the following:

1. Go to *Data collection* → *Templates*.
2. Mark the checkboxes of the templates to export.
3. Click *Export* below the list.

≡ Templates

Depending on the selected format, templates are exported to a local file with a default name:

- `zabbix_export_templates.yaml` - in YAML export (default option for export);
- `zabbix_export_templates.xml` - in XML export;
- `zabbix_export_templates.json` - in JSON export.

Importing

To import templates, do the following:

1. Go to *Data collection* → *Templates*.
2. Click *Import* in the top right corner.
3. Select the import file.
4. Click *Import* in the bottom right corner of the configuration form.

Import

* Import file

| Triggers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Graphs | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Web scenarios | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

Import

Cancel

If you mark the *Advanced options* checkbox, a detailed list of all importable elements will be displayed - mark or unmark each import rule as required.

If you click the checkbox in the *All* row, all elements below it will be marked/unmarked.

Import rules:

| Rule | Description |
|------------------------|--|
| <i>Update existing</i> | Existing elements will be updated using data from the import file. Otherwise, they will not be updated. |
| <i>Create new</i> | New elements will be created using data from the import file. Otherwise, they will not be created. |
| <i>Delete missing</i> | Existing elements not present in the import file will be removed. Otherwise, they will not be removed. If <i>Delete missing</i> is marked for <i>Template linkage</i> , current template linkage not present in the import file will be unlinked. Entities (items, triggers, graphs, etc.) inherited from the unlinked templates will not be removed (unless the <i>Delete missing</i> option is selected for each entity as well). |

On the next screen, you will be able to view the content of a template being imported. If this is a new template, all elements will be listed in green. If updating an existing template, new template elements will be highlighted in green; removed template elements will be highlighted in red; elements that have not changed will be listed on a gray background.

```

The menu on the left can be used to navigate through the list of changes. The *Updated* section highlights all changes made to existing template elements. The *Added* section lists new template elements. The elements in each section are grouped by element type; click the gray arrow to expand or collapse the group of elements.

Exported elements Exported elements are explained in the tables below.

| Element | Type | Description |
|-----------------|--------|---|
| template_groups | | (required) Root element for template groups. |
| uuid | string | (required) Unique identifier for this template group. |
| name | string | (required) Template group name. |
| host_groups | | (required) Root element for host groups that are used by host prototypes. |
| uuid | string | (required) Unique identifier for this host group. |
| name | string | (required) Host group name. |
| templates | | Root element for templates . |

Templates

| Element | Type | Description |
|-------------|--------|---|
| uuid | string | (required) Unique identifier for this template. |
| template | string | (required) Unique template name. |
| name | string | Visible template name. |
| description | text | Template description. |
| vendor | | Root element for template vendor (present if the exported template contains vendor data). |
| name | string | (required) Template vendor name. |

| Element | Type | Description |
|-----------------|--------|---|
| version | string | (required) Template version. For out-of-the-box templates , version is displayed as follows: major version of Zabbix, delimiter ("-"), revision number (increased with each new version of the template, and reset with each major version of Zabbix). For example, 7.0-0, 7.0-3, 7.2-0, 7.2-3. |
| templates | | Root element for linked templates. |
| name | string | (required) Template name. |
| groups | | Root element for template groups. |
| name | string | (required) Template group name. |
| items | | Root element for template items . |
| discovery_rules | | Root element for template low-level discovery rules . |
| httptests | | Root element for template web scenarios . |
| tags | | Root element for template tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |
| macros | | Root element for template user macros. |
| macro | string | (required) User macro name. |
| type | string | User macro type. Possible values: ¹ TEXT (0, default), SECRET_TEXT (1), VAULT (2). See also: User macro object (type). |
| value | string | User macro value. |
| description | string | User macro description. |
| dashboards | | Root element for template dashboards . |
| valuemaps | | Root element for template value maps . |

Template items

| Element | Type | Description |
|---------------|--------|---|
| uuid | string | (required) Unique identifier for this item. |
| name | string | (required) Item name. |
| type | string | Item type. Possible values: ¹ ZABBIX_PASSIVE (0, default), TRAP (2), SIMPLE (3), INTERNAL (5), ZABBIX_ACTIVE (7), EXTERNAL (10), ODBC (11), IPMI (12), SSH (13), TELNET (14), CALCULATED (15), JMX (16), SNMP_TRAP (17), DEPENDENT (18), HTTP_AGENT (19), SNMP_AGENT (20), ITEM_TYPE_SCRIPT (21), ITEM_TYPE_BROWSER (22). |
| snmp_oid | string | (required for SNMP_AGENT items) SNMP object ID. |
| key | string | (required) Item key. |
| delay | string | Update interval of the item. Default: 1m. The value will always be 0 for TRAP items. |
| history | string | Time period (using time suffix , user macro or LLD macro) of how long the history data should be stored. Default: 31d. |
| trends | string | Time period (using time suffix , user macro or LLD macro) of how long the trends data should be stored. Default: 365d. |
| status | string | Item status. Possible values: ¹ ENABLED (0, default), DISABLED (1). |
| value_type | string | Received value type. Possible values: ¹ FLOAT (0), CHAR (1), LOG (2), UNSIGNED (3, default), TEXT (4), BINARY (5). |
| allowed_hosts | string | List of comma-delimited IP addresses of hosts allowed to send data for the item. Supported for TRAP and HTTP_AGENT items. |
| units | string | Received value units (bps, B, etc.). |
| params | text | Additional parameters depending on the type of the item (executed script for SSH and TELNET items; SQL query for ODBC items; formula for CALCULATED items; the script for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items). |
| ipmi_sensor | string | IPMI sensor. Supported for IPMI items. |

| Element | Type | Description |
|------------------|--------|---|
| authtype | string | Authentication type. Supported for SSH and HTTP_AGENT items. Possible values for SSH items: ¹ PASSWORD (0, default), PUBLIC_KEY (1). Possible values for HTTP_AGENT items: ¹ NONE (0, default), BASIC (1), NTLM (2). |
| username | string | (required for SSH and TELNET items) Username for authentication. Supported for SIMPLE, ODBC, JMX and HTTP_AGENT items. When used for JMX items, password (see below) should also be specified or both elements should be left blank. |
| password | string | (required for SSH and TELNET items) Password for authentication. Supported for SIMPLE, ODBC, JMX and HTTP_AGENT items. When used for JMX items, username (see above) should also be specified or both elements should be left blank. |
| publickey | string | (required for SSH items) Name of the public key file. |
| privatekey | string | (required for SSH items) Name of the private key file. |
| description | text | Item description. |
| inventory_link | string | Host inventory field that is populated by the item. Possible values: ¹ NONE (0), ALIAS (4), etc. (see Host inventory for supported fields). |
| valuemap | | Root element for item value maps. |
| name | string | (required) Name of the value map to use for the item. |
| logtimefmt | string | Format of the time in log entries. Supported for items of LOG value type. |
| preprocessing | | Root element for item value preprocessing. |
| step | | Root element for template item value preprocessing steps . |
| jmx_endpoint | string | JMX endpoint. Supported for JMX items. |
| master_item | | (required for DEPENDENT items) Root element for dependent item's master item. |
| key | string | (required) Dependent item's master item key. |
| timeout | string | Item data polling request timeout. Supported for Timeouts list of item types. |
| url | string | (required for HTTP_AGENT items) URL string. |
| query_fields | | Root element for query parameters. Supported for HTTP_AGENT items. |
| name | string | (required for HTTP_AGENT items) Query parameter name. |
| value | string | Query parameter value. Supported for HTTP_AGENT items. |
| parameters | | Root element for user-defined parameters. Supported for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items. |
| name | string | (required for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items) User-defined parameter name. |
| value | string | User-defined parameter value. Supported for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items. |
| posts | string | HTTP(S) request body data. Supported for HTTP_AGENT items. |
| status_codes | string | Ranges of required HTTP status codes, separated by commas. Supported for HTTP_AGENT items. |
| follow_redirects | string | Follow response redirects while polling data. Supported for HTTP_AGENT items. Possible values: ¹ NO (0), YES (1, default). |
| post_type | string | Type of post data body. Supported for HTTP_AGENT items. Possible values: ¹ RAW (0, default), JSON (2), XML (3). |
| http_proxy | string | HTTP(S) proxy connection string. Supported for HTTP_AGENT items. |
| headers | | Root element for HTTP(S) request headers. Supported for HTTP_AGENT items. |
| name | string | (required for HTTP_AGENT items) Header name. |
| value | string | (required for HTTP_AGENT items) Header value. |
| retrieve_mode | string | What part of response should be stored. Supported for HTTP_AGENT items. Possible values: ¹ BODY (0, default), HEADERS (1), BOTH (2). |

| Element | Type | Description |
|------------------|--------|--|
| request_method | string | Request method type. Supported for HTTP_AGENT items. Possible values: ¹ GET (0, default), POST (1), PUT (2), HEAD (3). |
| output_format | string | How to process response. Supported for HTTP_AGENT items. Possible values: ¹ RAW (0, default), JSON (1). |
| allow_traps | string | Allow to populate value similarly to the trapper item. Supported for HTTP_AGENT items. Possible values: ¹ NO (0, default), YES (1). |
| ssl_cert_file | string | Public SSL Key file path. Supported for HTTP_AGENT items. |
| ssl_key_file | string | Private SSL Key file path. Supported for HTTP_AGENT items. |
| ssl_key_password | string | Password for SSL Key file. Supported for HTTP_AGENT items. |
| verify_peer | string | Whether to validate that the host's certificate is authentic. Supported for HTTP_AGENT items. Possible values: ¹ NO (0, default), YES (1). |
| verify_host | string | Whether to validate that the host name for the connection matches the one in the host's certificate. Supported for HTTP_AGENT items. Possible values: ¹ NO (0, default), YES (1). |
| tags | | Root element for item tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |
| triggers | | Root element for template item triggers . |

Note:

See also: **Item object** (refer to the relevant property with a matching name).

Template item value preprocessing steps

| Element | Type | Description |
|----------------------|--------|---|
| type | string | (required) The item value preprocessing step type. Possible values: ¹ MULTIPLIER (1), RTRIM (2), LTRIM (3), TRIM (4), REGEX (5), BOOL_TO_DECIMAL (6), OCTAL_TO_DECIMAL (7), HEX_TO_DECIMAL (8), SIMPLE_CHANGE (9, calculated: received value - previous value), CHANGE_PER_SECOND (10, calculated: (received value - previous value)/(time now - time of last check)), XMLPATH (11), JSONPATH (12), IN_RANGE (13), MATCHES_REGEX (14), NOT_MATCHES_REGEX (15), CHECK_JSON_ERROR (16), CHECK_XML_ERROR (17), CHECK_REGEX_ERROR (18), DISCARD_UNCHANGED (19), DISCARD_UNCHANGED_HEARTBEAT (20), JAVASCRIPT (21), PROMETHEUS_PATTERN (22), PROMETHEUS_TO_JSON (23), CSV_TO_JSON (24), STR_REPLACE (25), CHECK_NOT_SUPPORTED (26), XML_TO_JSON (27), SNMP_WALK_VALUE (28), SNMP_WALK_TO_JSON (29), SNMP_GET_VALUE (30). |
| parameters | | (required) Root element for parameters of the item value preprocessing step. |
| parameter | string | Individual parameter of the item value preprocessing step. |
| error_handler | string | Action type used in case of preprocessing step failure. Possible values: ¹ ORIGINAL_ERROR (0, default), DISCARD_VALUE (1), CUSTOM_VALUE (2), CUSTOM_ERROR (3). |
| error_handler_params | string | Error handler parameters. |

Note:

See also: **Item preprocessing object** (refer to the relevant property with a matching name).

Template item triggers

| Element | Type | Description |
|---------------------|--------|--|
| uuid | string | (required) Unique identifier for this trigger. |
| expression | string | (required) Trigger expression. |
| recovery_mode | string | Basis for generating OK events. Possible values: ¹ EXPRESSION (0, default), RECOVERY_EXPRESSION (1), NONE (2). |
| recovery_expression | string | Trigger recovery expression. |
| correlation_mode | string | Correlation mode (no event correlation or event correlation by tag). Possible values: ¹ DISABLED (0, default), TAG_VALUE (1). |
| correlation_tag | string | The tag name to be used for event correlation. |
| name | string | (required) Trigger name. |
| event_name | string | Event name. |
| opdata | string | Operational data. |
| url_name | string | Label for the URL associated with the trigger. |
| url | string | URL associated with the trigger. |
| status | string | Trigger status. Possible values: ¹ ENABLED (0, default), DISABLED (1). |
| priority | string | Trigger severity. Possible values: ¹ NOT_CLASSIFIED (0, default), INFO (1), WARNING (2), AVERAGE (3), HIGH (4), DISASTER (5). |
| description | text | Trigger description. |
| type | string | Event generation type (single problem event or multiple problem events). Possible values: ¹ SINGLE (0, default), MULTIPLE (1). |
| manual_close | string | Manual closing of problem events. Possible values: ¹ NO (0, default), YES (1). |
| dependencies | | Root element for dependencies. |
| name | string | (required) Dependency trigger name. |
| expression | string | (required) Dependency trigger expression. |
| recovery_expression | string | Dependency trigger recovery expression. |
| tags | | Root element for trigger tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |

Note:

See also: **Trigger object** (refer to the relevant property with a matching name).

Template low-level discovery rules

Attention:

Most template low-level discovery rule elements are the same as for **template items**. The table below describes those elements that differ from template items.

| Element | Type | Description |
|-----------------------|--------|--|
| type | string | Item type. Possible values: ¹ ZABBIX_PASSIVE (0, default), TRAP (2), SIMPLE (3), INTERNAL (5), ZABBIX_ACTIVE (7), EXTERNAL (10), ODBC (11), IPMI (12), SSH (13), TELNET (14), JMX (16), DEPENDENT (18), HTTP_AGENT (19), SNMP_AGENT (20), ITEM_TYPE_SCRIPT (21), ITEM_TYPE_BROWSER (22). |
| key | string | (required) The low-level discovery rule key. |
| filter | | Root element for template low-level discovery rule filters . |
| lifetime | string | Time period (using seconds, time suffix , or user macro), after which no longer discovered resources will be deleted. Default: 7d. |
| lifetime_type | string | Scenario for deleting lost LLD resources. Possible values: DELETE_NEVER, DELETE_IMMEDIATELY, DELETE_AFTER. |
| enabled_lifetime | string | Time period (using seconds, time suffix , or user macro), after which no longer discovered resources will be disabled. |
| enabled_lifetime_type | string | Scenario for disabling lost LLD resources. Possible values: DISABLE_NEVER, DISABLE_IMMEDIATELY, DISABLE_AFTER. |
| item_prototypes | | Root element for template item prototype elements, which are the same as for template items . |

| Element | Type | Description |
|--------------------|--------|---|
| trigger_prototypes | | Root element for template trigger prototype elements, which are the same as for template item triggers . |
| graph_prototypes | | Root element for template graph prototype elements, which are the same as for host graphs . |
| host_prototypes | | Root element for template host prototype elements, which are the same as for hosts . |
| master_item | string | (required for DEPENDENT rules) Root element for the dependent rule's master item. |
| lld_macro_paths | | Root element for low-level discovery rule macro paths. |
| lld_macro | string | (required) Low-level discovery rule macro name. |
| path | string | (required) Selector for value, which will be assigned to the corresponding macro. |
| preprocessing | | Root element for low-level discovery rule value preprocessing. |
| step | | Root element for low-level discovery rule value preprocessing step elements, which are the same as for template item value preprocessing steps , except with fewer possible values. See also: LLD rule preprocessing object . |
| overrides | | Root element for low-level discovery rule override rules. |
| name | string | (required) Unique override name. |
| step | string | (required) Unique order number of the override. |
| stop | string | Stop processing next overrides if matches. |
| filter | | Root element for template low-level discovery rule override rule filter elements, which are the same as for template low-level discovery rule filters . |
| operations | | Root element for template low-level discovery rule override operations . |

Note:

See also: **LLD rule object** (refer to the relevant property with a matching name).

Template low-level discovery rule filters

| Element | Type | Description |
|------------|--------|---|
| evaltype | string | Override filter condition evaluation method. Possible values: ¹ AND_OR (0, default), AND (1), OR (2), FORMULA (3). |
| formula | string | Custom calculation formula for filter conditions. |
| conditions | | Root element for filter conditions. |
| macro | string | (required) The name of the low-level discovery macro to perform the check on. |
| value | string | Value to compare with. |
| operator | string | Condition operator. Possible values: ¹ MATCHES_REGEX (8, default), NOT_MATCHES_REGEX (9). |
| formulaid | string | (required) Arbitrary unique ID that is used to reference a condition from the custom expression. Can only contain capital-case letters. The ID must be defined by the user when modifying filter conditions, but will be generated anew when requesting them afterward. |

Note:

See also: **LLD rule filter object** (refer to the relevant property with a matching name).

Template low-level discovery rule override operations

| Element | Type | Description |
|-----------------|--------|--|
| operationobject | string | Object to which the operation is applied. Possible values: ¹ ITEM_PROTOTYPE (0), TRIGGER_PROTOTYPE (1), GRAPH_PROTOTYPE (2), HOST_PROTOTYPE (3). |
| operator | string | Override condition operator. Possible values: ¹ EQUAL (1), NOT_EQUAL (2), LIKE (3), NOT_LIKE (4), REGEXP (5), NOT_REGEXP (6). |
| value | string | A regular expression or a string for the override condition operator. |
| status | string | Status of the object upon the override operation. |
| discover | string | Whether the object is added as a result of the discovery. |
| delay | string | Update interval set for the item prototype upon the override operation. |
| history | string | History storage period set for the item prototype upon the override operation. |

| Element | Type | Description |
|----------------|--------|--|
| trends | string | Trend storage period set for the item prototype upon the override operation. |
| severity | string | Trigger prototype severity set upon the override operation. |
| tags | | Root element for the tags set for the object upon the override operation. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |
| templates | | Root element for the templates linked to the host prototype upon the override operation. |
| name | string | (required) Template name. |
| inventory_mode | string | Host prototype inventory mode set upon the override operation. |

Note:

See also: **LLD rule override operation object** (refer to the relevant property with a matching name).

Template web scenarios

| Element | Type | Description |
|------------------|---------|---|
| uuid | string | (required) Unique identifier for this web scenario. |
| name | string | (required) Web scenario name. |
| delay | string | Frequency (using seconds, time suffix , or user macro) of executing web scenario. Default: 1m. |
| attempts | integer | The number of attempts for executing web scenario steps. Possible values: ¹ 1-10 (default: 1). |
| agent | string | Client agent. Zabbix will pretend to be the selected browser. This is useful when a website returns different content for different browsers. Default: Zabbix. |
| http_proxy | string | Proxy that will be used by the web scenario given as: <code>http://[username[:password]@]proxy.example.com[:port]</code> |
| variables | | Root element for web scenario variables that may be used in scenario steps. |
| name | string | (required) Variable name. |
| value | text | (required) Variable value. |
| headers | | Root element for HTTP headers to be sent when performing a request. Headers should be listed using the same syntax as they would appear in the HTTP protocol. |
| name | string | (required) Header name. |
| value | text | (required) Header value. |
| status | string | Web scenario status. Possible values: ¹ ENABLED (0, default), DISABLED (1). |
| authentication | string | Authentication method. Possible values: ¹ NONE (0, default), BASIC (1), NTLM (2). |
| http_user | string | User name used for BASIC (HTTP) or NTLM authentication. |
| http_password | string | Password used for BASIC (HTTP) or NTLM authentication. |
| verify_peer | string | Verify the SSL certificate of the web server. Possible values: ¹ NO (0, default), YES (1). |
| verify_host | string | Verify that the <i>Common Name</i> field or the <i>Subject Alternate Name</i> field of the web server certificate matches. Possible values: ¹ NO (0, default), YES (1). |
| ssl_cert_file | string | Name of the SSL certificate file used for client authentication (must be in PEM format). |
| ssl_key_file | string | Name of the SSL private key file used for client authentication (must be in PEM format). |
| ssl_key_password | string | SSL private key file password. |
| steps | | (required) Root element for template web scenario steps . |
| tags | | Root element for web scenario tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |

Note:

See also: **Web scenario object** (refer to the relevant property with a matching name).

Template web scenario steps

| Element | Type | Description |
|------------------|--------|--|
| name | string | (required) Web scenario step name. |
| url | string | (required) URL for monitoring. |
| query_fields | | Root element for query parameters (an array of HTTP fields to be added to the URL when performing a request). |
| name | string | (required) Query parameter name. |
| value | string | Query parameter value. |
| posts | | Root element for HTTP POST variables (a string (raw post data) or an array of HTTP fields (form field data)). |
| name | string | (required) Post field name. |
| value | string | (required) Post field value. |
| variables | | Root element of step-level variables (macros) that should be applied after this step. If the variable value has a 'regex:' prefix, then its value is extracted from the data returned by this step according to the regular expression pattern following the 'regex:' prefix |
| name | string | (required) Variable name. |
| value | text | (required) Variable value. |
| headers | | Root element for HTTP headers to be sent when performing a request. |
| name | string | (required) Header name. |
| value | text | (required) Header value. |
| follow_redirects | string | Follow HTTP redirects. Possible values: ¹ NO (0), YES (1, default). |
| retrieve_mode | string | HTTP response retrieve mode. Possible values: ¹ BODY (0, default), HEADERS (1), BOTH (2). |
| timeout | string | Timeout (using seconds, time suffix , or user macro) of step execution. Default: 15s. |
| required | string | Text that must be present in the response (ignored if empty). |
| status_codes | string | A comma-delimited list of accepted HTTP status codes (e.g., 200–201, 210–299; ignored if empty). |

Note:

See also: **Web scenario step object** (refer to the relevant property with a matching name).

Template dashboards

| Element | Type | Description |
|------------|---------|--|
| uuid | string | (required) Unique identifier for this dashboard. |
| name | string | (required) Template dashboard name. |
| display | integer | Display period of dashboard pages. |
| period | | |
| auto_start | string | Slideshow auto start. Possible values: ¹ NO (0), YES (1, default). |
| pages | | Root element for template dashboard pages. |
| name | string | Page name. |
| display | integer | Page display period. |
| period | | |
| sortorder | integer | Page sorting order. |
| widgets | | Root element for template dashboard widgets . |

Note:

See also: **Template dashboard object** (refer to the relevant property with a matching name).

Template dashboard widgets

| Element | Type | Description |
|---------|--------|-------------------------|
| type | string | (required) Widget type. |
| name | string | Widget name. |

| Element | Type | Description |
|-------------|---------|--|
| x | integer | Horizontal position from the left side of the template dashboard. Possible values: ¹ 0-71. |
| y | integer | Vertical position from the top of the template dashboard. Possible values: ¹ 0-63. |
| width | integer | Widget width. Possible values: ¹ 1-72. |
| height | integer | Widget height. Possible values: ¹ 1-64. |
| hide_header | string | Hide widget header. Possible values: ¹ NO (0, default), YES (1). |
| fields | | Root element for the template dashboard widget fields. |
| type | string | (required) Widget field type. Possible values: ¹ INTEGER (0), STRING (1), ITEM (4), ITEM_PROTOTYPE (5), GRAPH (6), GRAPH_PROTOTYPE (7), MAP (8), SERVICE (9), SLA (10), USER (11), ACTION (12), MEDIA_TYPE (13). |
| name | string | (required) Widget field name. |
| value | mixed | (required) Widget field value, depending on the field type. |

Note:

See also: [Template dashboard widget object](#) (refer to the relevant property with a matching name).

Template value maps

| Element | Type | Description |
|----------|--------|--|
| uuid | string | (required) Unique identifier for this value map. |
| name | string | (required) Value map name. |
| mapping | | Root element for mappings. |
| type | string | Mapping match type. Possible values: ¹ EQUAL (0, default), GREATER_OR_EQUAL (2), LESS_OR_EQUAL (3), IN_RANGE (4), REGEXP (5), DEFAULT (6). |
| value | string | Original value. |
| newvalue | string | (required) Value to which the original value is mapped to. |

Note:

See also: [Value map object](#) (refer to the relevant property with a matching name).

Footnotes ¹ API integer values in brackets, for example, ENABLED (0), are mentioned only for reference. For more information, see the linked API object page in the table entry or at the end of each section.

4 Hosts

Overview

Hosts are [exported](#) with many related objects and object relations.

Host export contains:

- Linked [host groups](#)
- Host data
- Template linkage
- Host group linkage
- Host interfaces
- Directly linked items
- Directly linked triggers
- Directly linked discovery rules with all prototypes
- Directly linked web scenarios

- Host macros
- Host inventory data
- Value maps
- Linked **graphs**

Exporting

To export hosts, do the following:

1. Go to *Data collection* → *Hosts*.
2. Mark the checkboxes of the hosts to export.
3. Click *Export* below the list.

≡ Hosts

| <input type="checkbox"/> | Name ▲ | Items | Triggers | Graphs | Discovery | Web |
|-------------------------------------|---------|-------|----------|--------|-----------|-----|
| <input checked="" type="checkbox"/> | Server1 | Items | Triggers | Graphs | Discovery | Web |

1 selected

Enable
Disable
Export

YAML
XML
JSON

Mass update
Delete

Depending on the selected format, hosts are exported to a local file with a default name:

- `zabbix_export_hosts.yaml` - in YAML export (default option for export);
- `zabbix_export_hosts.xml` - in XML export;
- `zabbix_export_hosts.json` - in JSON export.

Importing

To import hosts, do the following:

1. Go to *Data collection* → *Hosts*.
2. Click *Import* in the top right corner.
3. Select the import file.
4. Click *Import* in the bottom right corner of the configuration form.

Import

* Import file

Browse...

zbx_export_hosts.yaml

Advanced options

☒

| Rules | Update existing | Create new | Delete missing |
|------------------|-------------------------------------|-------------------------------------|-------------------------------------|
| All | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Host groups | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | |
| Hosts | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | |
| Value mappings | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Template linkage | | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Items | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Discovery rules | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Triggers | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Graphs | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |
| Web scenarios | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> |

Import

Cancel

If you mark the *Advanced options* checkbox, a detailed list of all importable elements will be displayed - mark or unmark each import rule as required.

If you click the checkbox in the *All* row, all elements below it will be marked/unmarked.

Import rules:

| Rule | Description |
|------------------------|--|
| <i>Update existing</i> | Existing elements will be updated using data from the import file. Otherwise, they will not be updated. |
| <i>Create new</i> | New elements will be created using data from the import file. Otherwise, they will not be created. |
| <i>Delete missing</i> | Existing elements not present in the import file will be removed. Otherwise, they will not be removed. If <i>Delete missing</i> is marked for <i>Template linkage</i> , current template linkage not present in the import file will be unlinked. Entities (items, triggers, graphs, etc.) inherited from the unlinked templates will not be removed (unless the <i>Delete missing</i> option is selected for each entity as well). |

A success or failure message of the import will be displayed in the frontend.

Export format

Export format in YAML:

```
zabbix_export:
  version: '7.2'
  host_groups:
    - uuid: f2481361f99448eea617b7b1d4765566

Exported elements Exported elements are explained in the tables below.

| Element | Type | Description |
|-------------|--------|---|
| version | string | (required) Zabbix version. |
| host_groups | | (required) Root element for host groups. |
| | uuid | (required) Unique identifier for this host group. |
| | name | (required) Host group name. |
| hosts | | Root element for hosts . |

Hosts

| Element | Type | Description |
|----------------|--------|---|
| host | string | (required) Unique host name. |
| name | string | Visible host name. |
| description | text | Host description. |
| monitored_by | string | Host is monitored by: SERVER, PROXY, or PROXY_GROUP. |
| proxy | | Root element for proxy. |
| | name | (required) Name of the proxy (if any) that monitors the host. |
| proxy_group | | Root element for proxy group. |
| | name | (required) Name of the proxy group (if any) that is used to monitor the host. |
| status | string | Host status. Possible values: ¹ ENABLED (0, default), DISABLED (1). |
| ipmi_authtype | string | IPMI session authentication type. Possible values: ¹ DEFAULT (-1, default), NONE (0), MD2 (1), MD5 (2), STRAIGHT (4), OEM (5), RMCP_PLUS (6). |
| ipmi_privilege | string | IPMI session privilege level. Possible values: ¹ CALLBACK (1), USER (2, default), OPERATOR (3), ADMIN (4), OEM (5). |

| Element | Type | Description |
|----------------------|--------|---|
| ipmi_username | string | Username for IPMI checks. |
| ipmi_password | string | Password for IPMI checks. |
| templates | | Root element for linked templates. |
| name | string | (required) Template name. |
| groups | | Root element for host groups to which the host belongs. |
| name | string | (required) Host group name. |
| interfaces | | Root element for host interfaces . |
| items | | Root element for host items . |
| discovery_rules | | Root element for host low-level discovery rules . |
| http_tests | | Root element for host web scenarios . |
| tags | | Root element for host tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |
| macros | | Root element for host macros. |
| macro | string | (required) User macro name. |
| type | string | User macro type. Possible values: ¹ TEXT (0, default), SECRET_TEXT (1), VAULT (2). |
| value | string | User macro value. |
| description | string | User macro description. |
| inventory | | Root element for host inventory. |
| <inventory_property> | string | Inventory property. All properties have their respective element (type, name, os, etc.; for example, see Export format). |
| inventory_mode | string | Inventory mode. Possible values: ¹ DISABLED (-1), MANUAL (0, default), AUTOMATIC (1). |
| valuemaps | | Root element for host value maps . |

Note:

See also: [Host object](#) (refer to the relevant property with a matching name).

Host interfaces

| Element | Type | Description |
|-----------------|--------|---|
| default | string | Whether this is the primary host interface. Note that there can be only one primary interface of one type on a host. Possible values: ¹ NO (0), YES (1, default). |
| type | string | Interface type. Possible values: ¹ ZABBIX (1, default), SNMP (2), IPMI (3), JMX (4). |
| useip | string | Whether to use IP as the interface for connecting to the host (otherwise, DNS will be used). Possible values: ¹ NO (0), YES (1, default). |
| ip | string | (required for IP connections) IP address (IPv4 or IPv6). |
| dns | string | (required for DNS connections) DNS name. |
| port | string | Port number. |
| details | | Root element for interface details. |
| version | string | Use this SNMP version. Possible values: ¹ SNMPV1 (1), SNMP_V2C (2, default), SNMP_V3 (3). |
| community | string | (required for SNMPv1 and SNMPv2 items) SNMP community. |
| max_repetitions | string | Max repetition value for native SNMP bulk requests (GetBulkRequest-PDUs). Supported for SNMPv2 and SNMPv3 items (discovery[] and walk[] items). Default: 10. |
| contextname | string | SNMPv3 context name. Supported for SNMPv3 items. |
| securityname | string | SNMPv3 security name. Supported for SNMPv3 items. |
| securitylevel | string | SNMPv3 security level. Supported for SNMPv3 items. Possible values: ¹ NOAUTHNOPRIV (0, default), AUTHNOPRIV (1), AUTHPRIV (2). |

| Element | Type | Description |
|----------------|--------|---|
| authprotocol | string | SNMPv3 authentication protocol. Supported for SNMPv3 items. Possible values: ¹ MD5 (0, default), SHA1 (1), SHA224 (2), SHA256 (3), SHA384 (4), SHA512 (5). |
| authpassphrase | string | SNMPv3 authentication passphrase. Supported for SNMPv3 items. |
| privprotocol | string | SNMPv3 privacy protocol. Supported for SNMPv3 items. Possible values: ¹ DES (0, default), AES128 (1), AES192 (2), AES256 (3), AES192C (4), AES256C (5). |
| privpassphrase | string | SNMPv3 privacy passphrase. Supported for SNMPv3 items. |
| bulk | string | Use bulk requests for SNMP. Possible values: ¹ NO (0), YES (1, default). |
| interface_ref | string | Interface reference name to be used in items (format: if<N>). |

Note:

See also: [Host interface object](#) (refer to the relevant property with a matching name).

Host items

| Element | Type | Description |
|---------------|--------|---|
| name | string | (required) Item name. |
| type | string | Item type. Possible values: ¹ ZABBIX_PASSIVE (0, default), TRAP (2), SIMPLE (3), INTERNAL (5), ZABBIX_ACTIVE (7), EXTERNAL (10), ODBC (11), IPMI (12), SSH (13), TELNET (14), CALCULATED (15), JMX (16), SNMP_TRAP (17), DEPENDENT (18), HTTP_AGENT (19), SNMP_AGENT (20), ITEM_TYPE_SCRIPT (21), ITEM_TYPE_BROWSER (22). |
| snmp_oid | string | (required for SNMP_AGENT items) SNMP object ID. |
| key | string | (required) Item key. |
| delay | string | Update interval of the item. Default: 1m. The value will always be 0 for TRAP items. |
| history | string | Time period (using time suffix , user macro or LLD macro) of how long the history data should be stored. Default: 31d. |
| trends | string | Time period (using time suffix , user macro or LLD macro) of how long the trends data should be stored. Default: 365d. |
| status | string | Item status. Possible values: ¹ ENABLED (0, default), DISABLED (1). |
| value_type | string | Received value type. Possible values: ¹ FLOAT (0), CHAR (1), LOG (2), UNSIGNED (3, default), TEXT (4), BINARY (5). |
| allowed_hosts | string | List of comma-delimited IP addresses of hosts allowed to send data for the item. Supported for TRAP and HTTP_AGENT items. |
| units | string | Received value units (bps, B, etc.). |
| params | text | Additional parameters depending on the type of the item (executed script for SSH and TELNET items; SQL query for ODBC items; formula for CALCULATED items; the script for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items). |
| ipmi_sensor | string | IPMI sensor. Supported for IPMI items. |
| authtype | string | Authentication type. Supported for SSH and HTTP_AGENT items. Possible values for SSH items: ¹ PASSWORD (0, default), PUBLIC_KEY (1). Possible values for HTTP_AGENT items: ¹ NONE (0, default), BASIC (1), NTLM (2). |
| username | string | (required for SSH and TELNET items) Username for authentication. Supported for SIMPLE, ODBC, JMX and HTTP_AGENT items. When used for JMX items, password (see below) should also be specified or both elements should be left blank. |

| Element | Type | Description |
|------------------|--------|--|
| password | string | (required for SSH and TELNET items) Password for authentication. Supported for SIMPLE, ODBC, JMX and HTTP_AGENT items. When used for JMX items, username (see above) should also be specified or both elements should be left blank. |
| publickey | string | (required for SSH items) Name of the public key file. |
| privatekey | string | (required for SSH items) Name of the private key file. |
| description | text | Item description. |
| inventory_link | string | Host inventory field that is populated by the item. Possible values: ¹ NONE (0), ALIAS (4), etc. (see Host inventory for supported fields). |
| valuemap | | Root element for item value maps. |
| name | string | (required) Name of the value map to use for the item. |
| logtimefmt | string | Format of the time in log entries. Supported for items of LOG value type. |
| preprocessing | | Root element for item value preprocessing. |
| step | | Root element for host item value preprocessing steps . |
| interface_ref | string | Reference to the host interface (format: <code>if<N></code>). |
| jmx_endpoint | string | JMX endpoint. Supported for JMX items. |
| master_item | | (required for DEPENDENT items) Root element for dependent item's master item. |
| key | string | (required) Dependent item's master item key. |
| timeout | string | Item data polling request timeout. Supported for the Timeouts list of item types. |
| url | string | (required for HTTP_AGENT items) URL string. |
| query_fields | | Root element for query parameters. Supported for HTTP_AGENT items. |
| name | string | (required for HTTP_AGENT items) Query parameter name. |
| value | string | Query parameter value. Supported for HTTP_AGENT items. |
| parameters | | Root element for user-defined parameters. Supported for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items. |
| name | string | (required for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items) User-defined parameter name. |
| value | string | User-defined parameter value. Supported for ITEM_TYPE_SCRIPT and ITEM_TYPE_BROWSER items. |
| posts | string | HTTP(S) request body data. Supported for HTTP_AGENT items. |
| status_codes | string | Ranges of required HTTP status codes, separated by commas. Supported for HTTP_AGENT items. |
| follow_redirects | string | Follow response redirects while polling data. Supported for HTTP_AGENT items. Possible values: ¹ NO (0), YES (1, default). |
| post_type | string | Type of post data body. Supported for HTTP_AGENT items. Possible values: ¹ RAW (0, default), JSON (2), XML (3). |
| http_proxy | string | HTTP(S) proxy connection string. Supported for HTTP_AGENT items. |
| headers | | Root element for HTTP(S) request headers. Supported for HTTP_AGENT items. |
| name | string | (required for HTTP_AGENT items) Header name. |
| value | string | (required for HTTP_AGENT items) Header value. |
| retrieve_mode | string | What part of response should be stored. Supported for HTTP_AGENT items. Possible values: ¹ BODY (0, default), HEADERS (1), BOTH (2). |
| request_method | string | Request method type. Supported for HTTP_AGENT items. Possible values: ¹ GET (0, default), POST (1), PUT (2), HEAD (3). |
| output_format | string | How to process response. Supported for HTTP_AGENT items. Possible values: ¹ RAW (0, default), JSON (1). |
| allow_traps | string | Allow to populate value similarly to the trapper item. Supported for HTTP_AGENT items. Possible values: ¹ NO (0, default), YES (1). |

| Element | Type | Description |
|------------------|--------|--|
| ssl_cert_file | string | Public SSL Key file path. Supported for HTTP_AGENT items. |
| ssl_key_file | string | Private SSL Key file path. Supported for HTTP_AGENT items. |
| ssl_key_password | string | Password for SSL Key file. Supported for HTTP_AGENT items. |
| verify_peer | string | Whether to validate that the host's certificate is authentic. Supported for HTTP_AGENT items. |
| verify_host | string | Whether to validate that the host name for the connection matches the one in the host's certificate. Supported for HTTP_AGENT items. Possible values: ¹ NO (0, default), YES (1). |
| tags | | Root element for item tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |
| triggers | | Root element for host item triggers . |

Note:

See also: **Item object** (refer to the relevant property with a matching name).

Host item value preprocessing steps

| Element | Type | Description |
|----------------------|--------|---|
| type | string | (required) The item value preprocessing step type. Possible values: ¹ MULTIPLIER (1), RTRIM (2), LTRIM (3), TRIM (4), REGEX (5), BOOL_TO_DECIMAL (6), OCTAL_TO_DECIMAL (7), HEX_TO_DECIMAL (8), SIMPLE_CHANGE (9, calculated: received value - previous value), CHANGE_PER_SECOND (10, calculated: (received value - previous value)/(time now - time of last check)), XMLPATH (11), JSONPATH (12), IN_RANGE (13), MATCHES_REGEX (14), NOT_MATCHES_REGEX (15), CHECK_JSON_ERROR (16), CHECK_XML_ERROR (17), CHECK_REGEX_ERROR (18), DISCARD_UNCHANGED (19), DISCARD_UNCHANGED_HEARTBEAT (20), JAVASCRIPT (21), PROMETHEUS_PATTERN (22), PROMETHEUS_TO_JSON (23), CSV_TO_JSON (24), STR_REPLACE (25), CHECK_NOT_SUPPORTED (26), XML_TO_JSON (27), SNMP_WALK_VALUE (28), SNMP_WALK_TO_JSON (29), SNMP_GET_VALUE (30). |
| parameters | | (required) Root element for parameters of the item value preprocessing step. |
| parameter | string | Individual parameter of the item value preprocessing step. |
| error_handler | string | Action type used in case of preprocessing step failure. Possible values: ¹ ORIGINAL_ERROR (0, default), DISCARD_VALUE (1), CUSTOM_VALUE (2), CUSTOM_ERROR (3). |
| error_handler_params | string | Error handler parameters. |

Note:

See also: **Item preprocessing object** (refer to the relevant property with a matching name).

Host item triggers

| Element | Type | Description |
|---------------------|--------|---|
| uuid | string | (required) Unique identifier for this trigger. |
| expression | string | (required) Trigger expression. |
| recovery_mode | string | Basis for generating OK events. Possible values: ¹ EXPRESSION (0, default), RECOVERY_EXPRESSION (1), NONE (2). |
| recovery_expression | string | Trigger recovery expression. |
| correlation_mode | string | Correlation mode (no event correlation or event correlation by tag). Possible values: ¹ DISABLED (0, default), TAG_VALUE (1). |
| correlation_tag | string | The tag name to be used for event correlation. |
| name | string | (required) Trigger name. |

| Element | Type | Description |
|---------------------|--------|--|
| event_name | string | Event name. |
| opdata | string | Operational data. |
| url_name | string | Label for the URL associated with the trigger. |
| url | string | URL associated with the trigger. |
| status | string | Trigger status. |
| priority | string | Possible values: ¹ ENABLED (0, default), DISABLED (1). Trigger severity. Possible values: ¹ NOT_CLASSIFIED (0, default), INFO (1), WARNING (2), AVERAGE (3), HIGH (4), DISASTER (5). |
| description | text | Trigger description. |
| type | string | Event generation type (single problem event or multiple problem events). Possible values: ¹ SINGLE (0, default), MULTIPLE (1). |
| manual_close | string | Manual closing of problem events. Possible values: ¹ NO (0, default), YES (1). |
| dependencies | | Root element for dependencies. |
| name | string | (required) Dependency trigger name. |
| expression | string | (required) Dependency trigger expression. |
| recovery_expression | string | Dependency trigger recovery expression. |
| tags | | Root element for trigger tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |

Note:

See also: **Trigger object** (refer to the relevant property with a matching name).

Host low-level discovery rules

Attention:

Most host low-level discovery rule elements are the same as for **host items**. The table below describes those elements that differ from host items.

| Element | Type | Description |
|-----------------------|--------|--|
| type | string | Item type. Possible values: ¹ ZABBIX_PASSIVE (0, default), TRAP (2), SIMPLE (3), INTERNAL (5), ZABBIX_ACTIVE (7), EXTERNAL (10), ODBC (11), IPMI (12), SSH (13), TELNET (14), JMX (16), DEPENDENT (18), HTTP_AGENT (19), SNMP_AGENT (20), ITEM_TYPE_SCRIPT (21), ITEM_TYPE_BROWSER (22). |
| key | string | (required) The low-level discovery rule key. |
| filter | | Root element for host low-level discovery rule filters . |
| lifetime | string | Time period (using seconds, time suffix , or user macro), after which no longer discovered resources will be deleted. Default: 7d. |
| lifetime_type | string | Scenario for deleting lost LLD resources. Possible values: DELETE_NEVER, DELETE_IMMEDIATELY, DELETE_AFTER. |
| enabled_lifetime | string | Time period (using seconds, time suffix , or user macro), after which no longer discovered resources will be disabled. |
| enabled_lifetime_type | string | Scenario for disabling lost LLD resources. Possible values: DISABLE_NEVER, DISABLE_IMMEDIATELY, DISABLE_AFTER. |
| item_prototypes | | Root element for host item prototype elements, which are the same as for host items . |
| trigger_prototypes | | Root element for host trigger prototype elements, which are the same as for host item triggers . |
| graph_prototypes | | Root element for host graph prototypes, which are the same as for host graphs . |
| host_prototypes | | Root element for host prototypes, which are the same as for hosts . |
| master_item | string | (required for DEPENDENT rules) Root element for the dependent rule's master item. |
| lld_macro_paths | | Root element for low-level discovery rule macro paths. |
| lld_macro | string | (required) Low-level discovery rule macro name. |
| path | string | (required) Selector for value, which will be assigned to the corresponding macro. |
| preprocessing | | Root element for low-level discovery rule value preprocessing. |

| Element | Type | Description |
|------------|--------|---|
| step | | Root element for low-level discovery rule value preprocessing step elements, which are the same as for host item value preprocessing steps , except with fewer possible values. See also: LLD rule preprocessing object . |
| overrides | | Root element for low-level discovery rule override rules. |
| name | string | (required) Unique override name. |
| step | string | (required) Unique order number of the override. |
| stop | string | Stop processing next overrides if matches. |
| filter | | Root element for low-level discovery rule override rule filter elements, which are the same as for host low-level discovery rule filters . |
| operations | | Root element for host low-level discovery rule override operations . |

Note:

See also: [LLD rule object](#) (refer to the relevant property with a matching name).

Host low-level discovery rule filters

| Element | Type | Description |
|------------|--------|---|
| evaltype | string | Override filter condition evaluation method. Possible values: ¹ AND_OR (0, default), AND (1), OR (2), FORMULA (3). |
| formula | string | Custom calculation formula for filter conditions. |
| conditions | | Root element for filter conditions. |
| macro | string | (required) The name of the low-level discovery macro to perform the check on. |
| value | string | Value to compare with. |
| operator | string | Condition operator. Possible values: ¹ MATCHES_REGEX (8, default), NOT_MATCHES_REGEX (9). |
| formulaid | string | (required) Arbitrary unique ID that is used to reference a condition from the custom expression. Can only contain capital-case letters. The ID must be defined by the user when modifying filter conditions, but will be generated anew when requesting them afterward. |

Note:

See also: [LLD rule filter object](#) (refer to the relevant property with a matching name).

Host low-level discovery rule override operations

| Element | Type | Description |
|-----------------|--------|--|
| operationobject | string | Object to which the operation is applied. Possible values: ¹ ITEM_PROTOTYPE (0), TRIGGER_PROTOTYPE (1), GRAPH_PROTOTYPE (2), HOST_PROTOTYPE (3). |
| operator | string | Override condition operator. Possible values: ¹ EQUAL (1), NOT_EQUAL (2), LIKE (3), NOT_LIKE (4), REGEXP (5), NOT_REGEXP (6). |
| value | string | A regular expression or a string for the override condition operator. |
| status | string | Status of the object upon the override operation. |
| discover | string | Whether the object is added as a result of the discovery. |
| delay | string | Update interval set for the item prototype upon the override operation. |
| history | string | History storage period set for the item prototype upon the override operation. |
| trends | string | Trend storage period set for the item prototype upon the override operation. |
| severity | string | Trigger prototype severity set upon the override operation. |
| tags | | Root element for the tags set for the object upon the override operation. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |
| templates | | Root element for the templates linked to the host prototype upon the override operation. |
| name | string | (required) Template name. |
| inventory_mode | string | Host prototype inventory mode set upon the override operation. |

Note:

See also: **LLD rule override operation object** (refer to the relevant property with a matching name).

Host web scenarios

| Element | Type | Description |
|------------------|---------|---|
| uuid | string | (required) Unique identifier for this web scenario. |
| name | string | (required) Web scenario name. |
| delay | string | Frequency (using seconds, time suffix , or user macro) of executing web scenario. Default: 1m. |
| attempts | integer | The number of attempts for executing web scenario steps. Possible values: 1-10 (default: 1). |
| agent | string | Client agent. Zabbix will pretend to be the selected browser. This is useful when a website returns different content for different browsers. Default: Zabbix. |
| http_proxy | string | Proxy that will be used by the web scenario given as: <code>http://[username[:password]@]proxy.example.com[:port]</code> |
| variables | | Root element for web scenario variables that may be used in scenario steps. |
| name | string | (required) Variable name. |
| value | text | (required) Variable value. |
| headers | | Root element for HTTP headers to be sent when performing a request. Headers should be listed using the same syntax as they would appear in the HTTP protocol. |
| name | string | (required) Header name. |
| value | text | (required) Header value. |
| status | string | Web scenario status. Possible values: ¹ ENABLED (0, default), DISABLED (1). |
| authentication | string | Authentication method. Possible values: ¹ NONE (0, default), BASIC (1), NTLM (2). |
| http_user | string | User name used for BASIC (HTTP) or NTLM authentication. |
| http_password | string | Password used for BASIC (HTTP) or NTLM authentication. |
| verify_peer | string | Verify the SSL certificate of the web server. Possible values: ¹ NO (0, default), YES (1). |
| verify_host | string | Verify that the <i>Common Name</i> field or the <i>Subject Alternate Name</i> field of the web server certificate matches. Possible values: ¹ NO (0, default), YES (1). |
| ssl_cert_file | string | Name of the SSL certificate file used for client authentication (must be in PEM format). |
| ssl_key_file | string | Name of the SSL private key file used for client authentication (must be in PEM format). |
| ssl_key_password | string | SSL private key file password. |
| steps | | (required) Root element for host web scenario steps . |
| tags | | Root element for web scenario tags. |
| tag | string | (required) Tag name. |
| value | string | Tag value. |

Note:

See also: **Web scenario object** (refer to the relevant property with a matching name).

Host web scenario steps

| Element | Type | Description |
|--------------|--------|---|
| name | string | (required) Web scenario step name. |
| url | string | (required) URL for monitoring. |
| query_fields | | Root element for query parameters (an array of HTTP fields to be added to the URL when performing a request). |
| name | string | (required) Query parameter name. |
| value | string | Query parameter value. |
| posts | | Root element for HTTP POST variables (a string (raw post data) or an array of HTTP fields (form field data)). |
| name | string | (required) Post field name. |
| value | string | (required) Post field value. |

| Element | Type | Description |
|------------------|--------|---|
| variables | | Root element of step-level variables (macros) that should be applied after this step. If the variable value has a 'regex:' prefix, then its value is extracted from the data returned by this step according to the regular expression pattern following the 'regex:' prefix |
| name | string | (required) Variable name. |
| value | text | (required) Variable value. |
| headers | | Root element for HTTP headers to be sent when performing a request. |
| name | string | (required) Header name. |
| value | text | (required) Header value. |
| follow_redirects | string | Follow HTTP redirects. Possible values: ¹ NO (0), YES (1, default). |
| retrieve_mode | string | HTTP response retrieve mode. Possible values: ¹ BODY (0, default), HEADERS (1), BOTH (2). |
| timeout | string | Timeout (using seconds, time suffix , or user macro) of step execution. Default: 15s. |
| required | string | Text that must be present in the response (ignored if empty). |
| status_codes | string | A comma-delimited list of accepted HTTP status codes (e.g., 200–201, 210–299; ignored if empty). |

Note:

See also: **Web scenario step object** (refer to the relevant property with a matching name).

Host graphs

| Element | Type | Description |
|------------------|---------|---|
| uuid | string | Unique identifier of the graph. |
| name | string | (required) Graph name. |
| width | integer | Graph width, in pixels. Used for preview and for pie/exploded graphs. Possible values: ¹ 20-65535 (default: 900). |
| height | integer | Graph height, in pixels. Used for preview and for pie/exploded graphs. Possible values: ¹ 20-65535 (default: 900). |
| yaxismin | double | Value of Y axis minimum. Supported for FIXED minimum value of Y axis. Default: 0. |
| yaxismax | double | Value of Y axis maximum. Supported for FIXED minimum value of X axis. Default: 0. |
| show_work_period | string | Highlight non-working hours. Supported for NORMAL and STACKED graphs. Possible values: ¹ NO (0), YES (1, default). |
| show_triggers | string | Display simple trigger values as a line. Supported for NORMAL and STACKED graphs. Possible values: ¹ NO (0), YES (1, default). |
| type | string | Graph type. Possible values: ¹ NORMAL (0, default), STACKED (1), PIE (2), EXPLODED (3). |
| show_legend | string | Display graph legend. Possible values: ¹ NO (0), YES (1, default). |
| show_3d | string | Enable 3D style. Supported for NORMAL and STACKED graphs. Possible values: ¹ NO (0, default), YES (1). |
| percent_left | double | Show the percentile line for left axis. Supported for NORMAL graphs. Default: 0. |
| percent_right | double | Show the percentile line for right axis. Supported for NORMAL graphs. Default: 0. |

| Element | Type | Description |
|-------------|--------|---|
| ymin_type_1 | string | Minimum value of Y axis. Supported for NORMAL and STACKED graphs. Possible values: ¹ CALCULATED (0, default), FIXED (1), ITEM (2). |
| ymin_item_1 | | (required if ymin_type_1 is set to ITEM) Root element for individual item details. |
| host | string | (required) Item host. |
| key | string | (required) Item key. |
| ymax_type_1 | string | Maximum value of Y axis. Supported for NORMAL and STACKED graphs. Possible values: ¹ CALCULATED (0, default), FIXED (1), ITEM (2). |
| ymax_item_1 | | (required if ymax_type_1 is set to ITEM) Root element for individual item details. |
| host | string | (required) Item host. |
| key | string | (required) Item key. |
| graph_items | | (required) Root element for host graph items . |

Note:

See also: **Graph object** (refer to the relevant property with a matching name).

Host graph items

| Element | Type | Description |
|-----------|---------|--|
| sortorder | integer | Draw order. The smaller value is drawn first. Can be used to draw lines or regions behind (or in front of) another. |
| drawtype | string | Draw style of the graph item. Supported for NORMAL graphs. Possible values: ¹ SINGLE_LINE (0, default), FILLED_REGION (1), BOLD_LINE (2), DOTTED_LINE (3), DASHED_LINE (4), GRADIENT_LINE (5). |
| color | string | Element color (6 symbols, hex). |
| yaxisside | string | Side of the graph where the graph item's Y scale will be drawn. Supported for NORMAL and STACKED graphs. |
| calc_fnc | string | Data to draw if more than one value exists for an item. Possible values: ¹ MIN (1), AVG (2, default), MAX (4), ALL (7; minimum, average, and maximum; supported for simple graphs), LAST (9, supported for pie/exploded graphs). |
| type | string | Graph item type. Possible values: ¹ SIMPLE (0, default), GRAPH_SUM (2; value of the item represents the whole pie; supported for pie/exploded graphs). |
| item | | (required) Individual item. |
| host | string | (required) Item host. |
| key | string | (required) Item key. |

Note:

See also: **Graph item object** (refer to the relevant property with a matching name).

Host value maps

| Element | Type | Description |
|----------|--------|--|
| uuid | string | (required) Unique identifier for this value map. |
| name | string | (required) Value map name. |
| mapping | | Root element for mappings. |
| type | string | Mapping match type. Possible values: ¹ EQUAL (0, default), GREATER_OR_EQUAL (2), LESS_OR_EQUAL (3), IN_RANGE (4), REGEXP (5), DEFAULT (6). |
| value | string | Original value. |
| newvalue | string | (required) Value to which the original value is mapped to. |

Note:

See also: **Value map object** (refer to the relevant property with a matching name).

Footnotes ¹ API integer values in brackets, for example, ENABLED (0), are mentioned only for reference. For more information, see the linked API object page in the table entry or at the end of each section.

5 Network maps

Overview

Network map **export** contains:

- All related images
- Map structure (all map settings, all contained elements with their settings, map links and map link status indicators)

Warning:

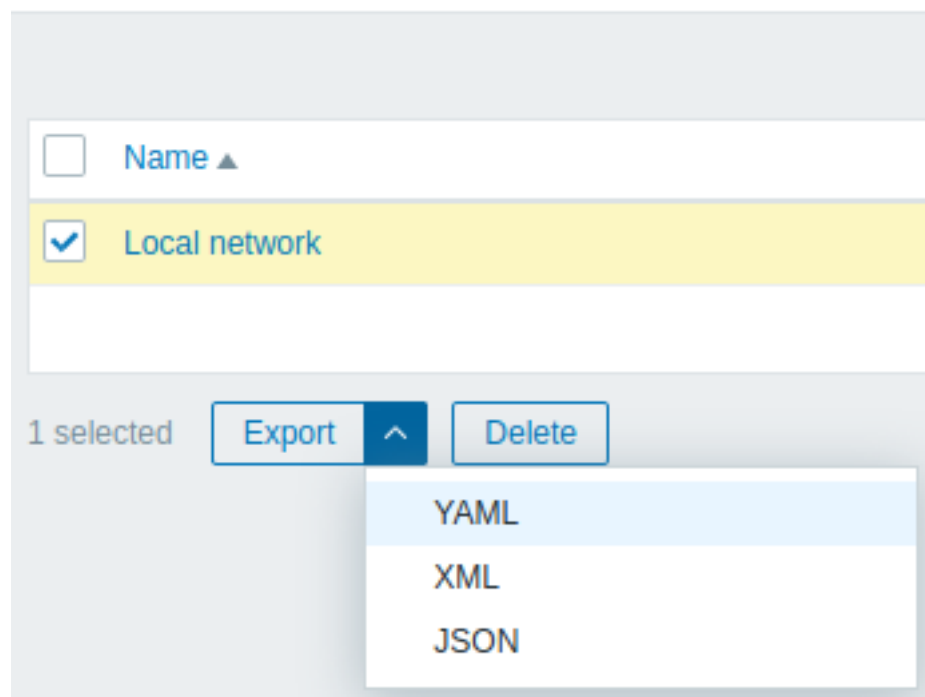

Any host groups, hosts, triggers, other maps or other elements that may be related to the exported map are not exported. Thus, if at least one of the elements the map refers to is missing, importing it will fail.

Exporting

To export network maps, do the following:

1. Go to *Monitoring* → *Maps*.
2. Mark the checkboxes of the network maps to export.
3. Click *Export* below the list.

≡ Maps

Depending on the selected format, maps are exported to a local file with a default name:

- `zabbix_export_maps.yaml` - in YAML export (default option for export);
- `zabbix_export_maps.xml` - in XML export;
- `zabbix_export_maps.json` - in JSON export.

Importing

To import network maps, do the following:

1. Go to *Monitoring* → *Maps*.
2. Click *Import* in the top right corner.
3. Select the import file.
4. Mark the required options in import rules.
5. Click *Import* in the bottom right corner of the configuration form.

Import

* Import file

Maps

☒

☒

Images

☐

☒

Import

Cancel

Import rules:

| Rule | Description |
|------------------------|---|
| <i>Update existing</i> | Existing maps will be updated using data from the import file. Otherwise, they will not be updated. |
| <i>Create new</i> | New maps will be created using data from the import file. Otherwise, they will not be created. |

If you uncheck both map options and check the respective options for images, images only will be imported. Image importing is only available to *Super admin* users.

A success or failure message of the import will be displayed in the frontend.

Warning:

If replacing an existing image, it will affect all maps that are using this image.

Export format

Export to YAML:

```
zabbix_export:
  version: '7.2'
  images:
    - name: Zabbix_server_3D_(128)

```

Exported elements Exported elements are explained in the table below.

| Element | Type | Description |
|--------------------|---------|--|
| images | | Root element for images. |
| name | string | Unique image name. |
| imagetype | integer | Image type. Possible values: 1 - Image; 2 - Background. |
| encodedImagestring | | Base64 encoded image. |
| maps | | Root element for maps . |

Maps

| Element | Type | Description |
|-----------------|---------|--|
| name | string | Unique map name. |
| width | integer | Map width, in pixels. |
| height | integer | Map height, in pixels. |
| label_type | integer | Map element label type. Possible values: 0 - Label; 1 - Host IP address; 2 - Element name; 3 - Status only; 4 - Nothing. |
| label_location | integer | Map element label location by default. Possible values: 0 - Bottom; 1 - Left; 2 - Right; 3 - Top. |
| highlight | integer | Enable icon highlighting for active triggers and host statuses. Possible values: 0 - No; 1 - Yes. |
| expandproblem | integer | Display problem trigger for elements with a single problem. Possible values: 0 - No; 1 - Yes. |
| markelements | integer | Highlight map elements that have recently changed their status. Possible values: 0 - No; 1 - Yes. |
| show_unack | integer | Problem display. Possible values: 0 - Count of all problems; 1 - Count of unacknowledged problems; 2 - Count of acknowledged and unacknowledged problems separately. |
| severity_min | integer | Minimum trigger severity to show on the map by default. Possible values: 0 - Not classified; 1 - Information; 2 - Warning; 3 - Average; 4 - High; 5 - Disaster. |
| show_suppressed | integer | Display problems, which would otherwise be suppressed (not shown) because of host maintenance. Possible values: 0 - No; 1 - Yes. |
| grid_size | integer | Cell size of a map grid in pixels. Supported if <code>grid_show</code> is set to 0. Possible values: 20, 40, 50, 75 or 100. |
| grid_show | integer | Display a grid in map configuration. Possible values: 0 - Yes; 1 - No. |
| grid_align | integer | Automatically align icons in map configuration. Possible values: 0 - Yes; 1 - No. |

| Element | Type | Description |
|------------------------|---------|--|
| label_format | integer | Use advanced label configuration. Possible values: 0 - No; 1 - Yes. |
| label_type_host | integer | Display label as host label. Supported if label_format is set to 1. Possible values: 0 - Label; 1 - Host IP address; 2 - Element name; 3 - Status only; 4 - Nothing; 5 - Custom label. |
| label_type_hostgroup | integer | Display label as host group label. Supported if label_format is set to 1. Possible values: 0 - Label; 2 - Element name; 3 - Status only; 4 - Nothing; 5 - Custom label. |
| label_type_trigger | integer | Display label as trigger label. Supported if label_format is set to 1. Possible values: 0 - Label; 2 - Element name; 3 - Status only; 4 - Nothing; 5 - Custom label. |
| label_type_map | integer | Display label as map label. Supported if label_format is set to 1. Possible values: 0 - Label; 2 - Element name; 3 - Status only; 4 - Nothing; 5 - Custom label. |
| label_type_image | integer | Display label as image label. Supported if label_format is set to 1. Possible values: 0 - Label; 2 - Element name; 4 - Nothing; 5 - Custom label. |
| label_string_host | string | Custom label for host elements. Supported if label_type_host is set to 5. |
| label_string_hostgroup | string | Custom label for host group elements. Supported if label_type_hostgroup is set to 5. |
| label_string_trigger | string | Custom label for trigger elements. Supported if label_type_trigger is set to 5. |
| label_string_map | string | Custom label for map elements. Supported if label_type_map is set to 5. |
| label_string_image | string | Custom label for image elements. Supported if label_type_image is set to 5. |
| expand_macros | integer | Expand macros in labels in map configuration. Possible values: 0 - No; 1 - Yes. |
| background | | Root element for background image (if any). Supported if imagetype is set to 2. |
| name | string | Background image name. |

| Element | Type | Description |
|------------------|---------|--|
| iconmap | | Root element for icon mapping (if any). |
| name | string | Icon mapping name. |
| urls | | Root element for URLs used by maps or each map element. |
| name | string | Link name. |
| url | string | Link URL. |
| elementtype | integer | Map item type the link belongs to. Possible values: 0 - Host; 1 - Map; 2 - Trigger; 3 - Host group; 4 - Image. |
| selements | | Root element for map selements . |
| shapes | | Root element for map shapes. |
| type | integer | Shape type. Possible values: 0 - Rectangle; 1 - Ellipse. |
| x | integer | X coordinates of the shape in pixels. |
| y | integer | Y coordinates of the shape in pixels. |
| width | integer | Shape width. |
| height | integer | Shape height. |
| text | string | Text inside of shape. |
| font | integer | Text font style. Possible values: 0 - Georgia, serif; 1 - "Palatino Linotype", "Book Antiqua", Palatino, serif; 2 - "Times New Roman", Times, serif; 3 - Arial, Helvetica, sans-serif; 4 - "Arial Black", Gadget, sans-serif; 5 - "Comic Sans MS", cursive, sans-serif; 6 - Impact, Charcoal, sans-serif; 7 - "Lucida Sans Unicode", "Lucida Grande", sans-serif; 8 - Tahoma, Geneva, sans-serif; 9 - "Trebuchet MS", Helvetica, sans-serif; 10 - Verdana, Geneva, sans-serif; 11 - "Courier New", Courier, monospace; 12 - "Lucida Console", Monaco, monospace. |
| font_size | integer | Font size in pixels. |
| font_color | string | Font color represented in hexadecimal code. |
| text_halign | integer | Horizontal alignment of text. Possible values: 0 - Center; 1 - Left; 2 - Right. |
| text_valign | integer | Vertical alignment of text. Possible values: 0 - Middle; 1 - Top; 2 - Bottom. |
| border_type | integer | Type of the border for the shape. Possible values: 0 - None; 1 - Bold line; 2 - Dotted line; 3 - Dashed line. |
| border_width | integer | Width of the border in pixels. |
| border_color | string | Border color represented in hexadecimal code. |
| background_color | string | Background (fill) color represented in hexadecimal code. |
| zindex | integer | Value for ordering all shapes and lines (z-index). |
| lines | | Root element for map lines. |

| Element | Type | Description |
|--------------|---------|--|
| x1 | integer | X coordinates of the line point 1 in pixels. |
| y1 | integer | Y coordinates of the line point 1 in pixels. |
| x2 | integer | X coordinates of the line point 2 in pixels. |
| y2 | integer | Y coordinates of the line point 2 in pixels. |
| line_type | integer | Line type. Possible values: 0 - None; 1 - Bold line; 2 - Dotted line; 3 - Dashed line. |
| line_width | integer | Line width in pixels. |
| line_color | string | Line color represented in hexadecimal code. |
| zindex | integer | Value for ordering all shapes and lines (z-index). |
| links | | Root element for links between map elements. |
| drawtype | integer | Link style. Possible values: 0 - Line; 2 - Bold line; 3 - Dotted line; 4 - Dashed line. |
| color | string | Link color (6 symbols, hex). |
| label | string | Link label. |
| selementid1 | id | ID of one element to connect. |
| selementid2 | id | ID of the other element to connect. |
| linktriggers | | Root element for link status indicators . |

Note:

See also: **Map object** (refer to the relevant property with a matching name).

Map selements

| Element | Type | Description |
|----------------|---------|--|
| elementtype | integer | Map element type. Possible values: 0 - Host; 1 - Map; 2 - Trigger; 3 - Host group; 4 - Image. |
| elements | | Root element for Zabbix entities (host, host group, map, etc.) that are represented on the map. All entities have their respective element (host, etc.; see, for example, Export format). |
| label | string | Icon label. |
| label_location | integer | Label location. Possible values: -1 - Use map default; 0 - Bottom; 1 - Left; 2 - Right; 3 - Top. |
| x | integer | Location on the X axis. |
| y | integer | Location on the Y axis. |
| elementsubtype | integer | Element subtype. Supported if <code>elementtype</code> is set to 3. Possible values: 0 - Single host group; 1 - All host groups. |

| Element | Type | Description |
|------------------|---------|---|
| areatype | integer | Area size. Supported if <code>elementtype</code> is set to 1. Possible values: 0 - Same as whole map; 1 - Custom size. |
| width | integer | Width of area. Supported if <code>areatype</code> is set to 1. |
| height | integer | Height of area. Supported if <code>areatype</code> is set to 1. |
| viewtype | integer | Area placement algorithm. Supported if <code>elementsubtype</code> is set to 1. Possible values: 0 - Place evenly in the area. |
| use_iconmap | integer | Use icon mapping for this element. Relevant only if icon mapping is activated on map level. Possible values: 0 - No; 1 - Yes. |
| selementid | id | Unique element record ID. |
| icon_off | | Root element for image to use when element is in 'OK' status. |
| name | string | Unique image name. |
| icon_on | | Root element for image to use when element is in 'Problem' status. |
| name | string | Unique image name. |
| icon_disabled | | Root element for image to use when element is disabled. |
| name | string | Unique image name. |
| icon_maintenance | | Root element for image to use when element is in maintenance. |
| name | string | Unique image name. |
| urls | | Root element for URLs used by maps or each map element. |
| name | string | Link name. |
| url | string | Link URL. |
| evaltype | integer | Evaluation type for tags. |
| tags | | Root element for problem tags (for host and host group elements). If tags are given, only problems with these tags will be displayed on the map. |
| tag | string | Tag name. |
| value | string | Tag value. |
| operator | integer | Operator. |

Note:

See also: [Map element object](#) (refer to the relevant property with a matching name).

Map link status indicators

| Element | Type | Description |
|---------------------|---------|---|
| drawtype | integer | Link style when trigger is in the 'Problem' state. Possible values: 0 - Line; 2 - Bold line; 3 - Dotted line; 4 - Dashed line. |
| color | string | Link color (6 symbols, hex) when trigger is in the 'Problem' state. |
| trigger | | Root element for trigger used to indicate link status. |
| description | string | Trigger name. |
| expression | string | Trigger expression. |
| recovery_expression | string | Trigger recovery expression. |

Note:

See also: [Map link trigger object](#) (refer to the relevant property with a matching name).

6 Media types

Overview

Media types are **exported** with all related objects and object relations.

Exporting

To export media types, do the following:

1. Go to *Alerts* → *Media types*.
2. Mark the checkboxes of the media types to export.
3. Click *Export* below the list.

Media types

The screenshot shows the 'Media types' interface. At the top, there is a table with two columns: 'Name' and 'Type'. The first row is 'Helpdesk' with type 'Webhook'. Below the table, there are buttons: 'Enable', 'Disable', 'Export', and 'Delete'. The 'Export' button is highlighted, and a dropdown menu is open showing three options: 'YAML', 'XML', and 'JSON'.

Depending on the selected format, media types are exported to a local file with a default name:

- `zabbix_export_mediatypes.yaml` - in YAML export (default option for export);
- `zabbix_export_mediatypes.xml` - in XML export;
- `zabbix_export_mediatypes.json` - in JSON export.

Importing

To import media types, do the following:

1. Go to *Alerts* → *Media types*.
2. Click *Import* in the top right corner.
3. Select the import file.
4. Mark the required options in import rules.
5. Click *Import* in the bottom right corner of the configuration form.

The screenshot shows the 'Import' dialog box. It has a title bar with a question mark and a close button. The main content area has a section for 'Import file' with a 'Browse...' button and a text field containing 'zbx_export_mediatypes.yaml'. Below this, there is a section for 'Rules' with two options: 'Update existing' and 'Create new'. Under 'Media types', there are two checkboxes: 'Update existing' (unchecked) and 'Create new' (checked). At the bottom right, there are two buttons: 'Import' and 'Cancel'.

Import rules:

| Rule | Description |
|------------------------|---|
| <i>Update existing</i> | Existing elements will be updated using data from the import file. Otherwise, they will not be updated. |
| <i>Create new</i> | New elements will be created using data from the import file. Otherwise, they will not be created. |

A success or failure message of the import will be displayed in the frontend.

Export format

Export to YAML:

```
zabbix_export:
  version: '7.2'
  media_types:
    - name: Pushover
      type: WEBHOOK
      parameters:
        - name: endpoint
          value: 'https://api.pushover.net/1/messages.json'
        - name: eventid
          value: '{EVENT.ID}'
        - name: event_nseverity
          value: '{EVENT.NSEVERITY}'
        - name: event_source
          value: '{EVENT.SOURCE}'
        - name: event_value
          value: '{EVENT.VALUE}'
        - name: expire
          value: '1200'
        - name: message
          value: '{ALERT.MESSAGE}'
        - name: priority_average
          value: '0'
        - name: priority_default
          value: '0'
        - name: priority_disaster
          value: '0'
        - name: priority_high
          value: '0'
        - name: priority_information
          value: '0'
        - name: priority_not_classified
          value: '0'
        - name: priority_warning
          value: '0'
        - name: retry
          value: '60'
        - name: title
          value: '{ALERT.SUBJECT}'
        - name: token
          value: '<PUSHOVER TOKEN HERE>'
        - name: triggerid
          value: '{TRIGGER.ID}'
        - name: url
          value: '{$ZABBIX.URL}'
        - name: url_title
          value: Zabbix
        - name: user
          value: '{ALERT.SENDTO}'
      status: DISABLED
```

```

Exported elements

Exported elements are explained in the table below.

| Element | Type | Description |
|---------|--------|--|
| name | string | (required) Media type name. |
| type | string | (required) Transport used by the media type. Possible values: ¹ EMAIL (0), SMS (1), SCRIPT (2), WEBHOOK (4). |
| status | string | Whether the media type is enabled. Possible values: ¹ ENABLED (0, default), DISABLED (1) |

| Element | Type | Description |
|-------------------|---------|---|
| max_sessions | integer | The maximum number of alerts that can be processed in parallel. Possible values for SMS: ¹ 1 (default). Possible values for other media types: ¹ 0-100 (where 0 - unlimited). |
| attempts | integer | The maximum number of attempts to send an alert. Possible values: ¹ 1-10 (default: 3). |
| attempt_interval | string | The interval (using seconds or time suffix) between retry attempts. Possible values: ¹ 0-60s (default: 10s). |
| description | string | Media type description. |
| message_templates | | Root element for media type message templates. |
| event_source | string | (required) Event source. Possible values: ¹ TRIGGERS (0), DISCOVERY (1), AUTOREGISTRATION (2), INTERNAL (3), SERVICE (4). |
| operation_mode | string | Operation mode. Possible values: ¹ PROBLEM (0), RECOVERY (1), UPDATE (2). |
| subject | string | Message subject. |
| message | string | Message body. |

Note:

See also: **Media type object** (refer to the relevant property with a matching name).

Email

The following additional elements are exported only for the *Email* media type.

| Element | Type | Description |
|---------------------|---------|--|
| provider | string | Email provider. |
| smtp_server | string | SMTP server. |
| smtp_port | integer | SMTP server port to connect to. Default: 25. |
| smtp_helo | string | SMTP helo. |
| smtp_email | string | Email address from which notifications will be sent. |
| smtp_security | string | SMTP connection security level to use. Possible values: ¹ NONE (0, default), STARTTLS (1), SSL_OR_TLS (2). |
| smtp_verify_host | string | SSL verify host for SMTP. Possible values: ¹ NO (0, default), YES (1). |
| smtp_verify_peer | string | SSL verify peer for SMTP. Possible values: ¹ NO (0, default), YES (1). |
| smtp_authentication | string | SMTP authentication method to use. Possible values: ¹ NONE (0, default), PASSWORD (1). |
| username | string | Username. |
| password | string | Authentication password. |
| message_format | string | Message format. Possible values: ¹ TEXT (0), HTML (1, default). |

Note:

See also: **Media type object** (refer to the relevant property with a matching name).

SMS

The following additional elements are exported only for the *SMS* media type.

| Element | Type | Description |
|-----------|--------|---|
| gsm_modem | string | (required) Serial device name of the GSM modem. |

Note:

See also: **Media type object** (refer to the relevant property with a matching name).

Script

The following additional elements are exported only for the *Script* media type.

| Element | Type | Description |
|-------------|--------|---|
| script name | string | (required) Script name. |
| parameters | | Root element for script parameters. |
| sortorder | string | (required) Order of the script parameters passed to the script as command-line arguments. |
| value | string | Script parameter value. |

Note:

See also: **Media type object** (refer to the relevant property with a matching name).

Webhook

The following additional elements are exported only for the *Webhook* media type.

| Element | Type | Description |
|-----------------|--------|---|
| script | string | Script. |
| timeout | string | Javascript script HTTP request timeout interval. Possible values: ¹ 1-60s (default: 30s). |
| process_tags | string | Whether to process returned tags. Possible values: ¹ NO (0, default), YES (1). |
| show_event_menu | string | Indicates the presence of an entry in the event menu if the {EVENT.TAGS.*} macro was successfully resolved in event_menu_url and event_menu_name fields. Possible values: ¹ NO (0, default), YES (1). |
| event_menu_url | string | URL of the event menu entry. Supports {EVENT.TAGS.*} macro. |
| event_menu_name | string | Name of the event menu entry. Supports {EVENT.TAGS.*} macro. |
| parameters | | Root element for webhook media type parameters. |
| name | string | (required) Webhook parameter name. |
| value | string | Webhook parameter value. |

Note:

See also: **Media type object** (refer to the relevant property with a matching name).

Footnotes

¹ API integer values in brackets, for example, ENABLED (0), are mentioned only for reference. For more information, see the linked API object page in the table entry or at the end of each section.

15 Discovery

Please use the sidebar to access content in the Discovery section.

1 Network discovery

Overview

Zabbix offers automatic network discovery functionality that is effective and very flexible.

With network discovery properly set up you can:

- speed up Zabbix deployment
- simplify administration
- use Zabbix in rapidly changing environments without excessive administration

Zabbix network discovery is based on the following information:

- IP ranges
- Availability of external services (FTP, SSH, WEB, POP3, IMAP, TCP, etc)
- Information received from Zabbix agent (only unencrypted mode is supported)
- Information received from SNMP agent

It does NOT provide:

- Discovery of network topology

Network discovery basically consists of two phases: discovery and actions.

Discovery

Zabbix periodically scans the IP ranges defined in **network discovery rules**. The frequency of the check is configurable for each rule individually.

Each rule has a set of service checks defined to be performed for the IP range.

Discovery rules are processed by the discovery manager. The discovery manager creates a job per each rule with a list of tasks (network checks). Network checks are performed in parallel by the available discovery workers (the number is configurable in the frontend per each rule). Only checks with the same IP and port are scheduled sequentially because some devices will not accept parallel connections on the same port.

The queue size of network checks is limited to 2000000 or 4 GB of memory approximately. If the queue becomes full then the discovery rule will be skipped and a warning message will be printed in the log. You may use the `zabbix[discovery_queue]` internal item to monitor the number of discovery checks in the queue.

Discovery checks are processed independently from the other checks. If any checks do not find a service (or fail), other checks will still be processed.

Note:

If a discovery rule is changed during execution, then the current discovery execution will be aborted.

Every check of a service and a host (IP) performed by the network discovery module generates a discovery event.

| Event | Check of service result |
|---------------------------|---|
| <i>Service Discovered</i> | The service is 'up' after it was 'down' or when discovered for the first time. |
| <i>Service Up</i> | The service is 'up', after it was already 'up'. |
| <i>Service Lost</i> | The service is 'down' after it was 'up'. |
| <i>Service Down</i> | The service is 'down', after it was already 'down'. |
| <i>Host Discovered</i> | At least one service of a host is 'up' after all services of that host were 'down' or a service is discovered which belongs to a not registered host. |
| <i>Host Up</i> | At least one service of a host is 'up', after at least one service was already 'up'. |
| <i>Host Lost</i> | All services of a host are 'down' after at least one was 'up'. |
| <i>Host Down</i> | All services of a host are 'down', after they were already 'down'. |

Actions

Discovery events can be the basis of relevant **actions**, such as:

- Sending notifications
- Adding/removing hosts
- Enabling/disabling hosts
- Adding hosts to a group
- Removing hosts from a group
- Adding tags to a host
- Removing tags from a host
- Linking a template to hosts/unlinking a template from hosts
- Executing remote scripts

These actions can be configured with respect to the device type, IP, status, uptime/downtime, etc. For full details on configuring actions for network-discovery based events, see action **operation** and **conditions** pages.

Since network discovery actions are event-based, they will be triggered both when a discovered host is online and when it is offline. It is highly recommended to add an action **condition** *Discovery status: up* to avoid such actions as *Add host* being triggered upon

Service Lost/Service Down events. Otherwise, if a discovered host is manually removed, it will still generate *Service Lost/Service Down* events and will be recreated during the next discovery cycle.

Note:

Linking templates to a discovered host will fail collectively if any of the linkable templates has a unique entity (e.g. item key) that is the same as a unique entity (e.g. item key) already existing on the host or on another of the linkable templates.

Host creation

A host is added if the *Add host* operation is selected. A host is also added, even if the *Add host* operation is missing, if you select operations resulting in actions on a host. Such operations are:

- enable host
- disable host
- add host to a host group
- link template to a host

Created hosts are added to the *Discovered hosts* group (by default, configurable in *Administration* → *General* → *Other*). If you wish hosts to be added to another group, add a *Remove from host groups* operation (specifying "Discovered hosts") and also add an *Add to host groups* operation (specifying another host group), because a host must belong to a host group.

The IP address of the discovered device is the criterion for finding a host in the system. If a host with that IP address and interface type already exists, that host will be the target for performing operations.

If the IP address of the discovered host is changed or the interface is deleted, a new host will be created upon the next discovery.

Host naming

When adding hosts, a host name is the result of reverse DNS lookup or IP address if reverse lookup fails. Lookup is performed from the Zabbix server or Zabbix proxy, depending on which is doing the discovery. If lookup fails on the proxy, it is not retried on the server. If the host with such a name already exists, the next host would get **_2** appended to the name, then **_3** and so on.

It is also possible to override DNS/IP lookup and instead use an item value for host name, for example:

- You may discover multiple servers with Zabbix agent running using a Zabbix agent item for discovery and assign proper names to them automatically, based on the string value returned by this item
- You may discover multiple SNMP network devices using an SNMP agent item for discovery and assign proper names to them automatically, based on the string value returned by this item

If the host name has been set using an item value, it is not updated during the following discovery checks. If it is not possible to set host name using an item value, default value (DNS name) is used.

If a host already exists with the discovered IP address, a new host is not created. However, if the discovery action contains operations (link template, add to host group, etc), they are performed on the existing host.

Host removal

Hosts discovered by a network discovery rule are removed automatically from *Monitoring* → *Discovery* if a discovered entity is not in the rule's IP range any more. Hosts are removed immediately.

Interface creation when adding hosts

When hosts are added as a result of network discovery, they get interfaces created according to these rules:

- the services detected - for example, if an SNMP check succeeded, an SNMP interface will be created
- if a host responded both to Zabbix agent and SNMP requests, both types of interfaces will be created
- if uniqueness criteria are Zabbix agent or SNMP-returned data, the first interface found for a host will be created as the default one. Other IP addresses will be added as additional interfaces. Action's conditions (such as Host IP) do not impact adding interfaces. *Note* that this will work if all interfaces are discovered by the same discovery rule. If a different discovery rule discovers a different interface of the same host, an additional host will be added.
- if a host responded to agent checks only, it will be created with an agent interface only. If it would start responding to SNMP later, additional SNMP interfaces would be added.
- if 3 separate hosts were initially created, having been discovered by the "IP" uniqueness criteria, and then the discovery rule is modified so that hosts A, B and C have identical uniqueness criteria result, B and C are created as additional interfaces for A, the first host. The individual hosts B and C remain. In *Monitoring* → *Discovery* the added interfaces will be displayed in the "Discovered device" column, in black font and indented, but the "Monitored host" column will only display A, the first created host. "Uptime/Downtime" is not measured for IPs that are considered to be additional interfaces.

Changing proxy setting

The hosts discovered by different proxies are always treated as different hosts. While this allows to perform discovery on matching IP ranges used by different subnets, changing proxy for an already monitored subnet is complicated because the proxy changes must be also applied to all discovered hosts.

For example the steps to replace proxy in a discovery rule:

1. disable discovery rule
2. sync proxy configuration
3. replace the proxy in the discovery rule
4. replace the proxy for all hosts discovered by this rule
5. enable discovery rule

1 Configuring a network discovery rule

Overview

To configure a network discovery rule used by Zabbix to discover hosts and services:

- Go to *Data collection* → *Discovery*
- Click on *Create discovery rule* (or on the rule name to edit an existing one)
- Edit the discovery rule attributes

Rule attributes

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|---------------------|--|
| <i>Name</i> | Unique name of the rule. For example, "Local network". |
| <i>Discovery by</i> | Discovery is performed by: Server - by Zabbix server Proxy - by Zabbix proxy (selected in the proxy name field) |
| <i>IP range</i> | The range of IP addresses for discovery. It may have the following formats: Single IP: 192.168.1.33 Range of IP addresses: 192.168.1-10.1-255. The range is limited by the total number of covered addresses (less than 64K). IP mask: 192.168.4.0/24 supported IP masks: /16 - /30 for IPv4 addresses /112 - /128 for IPv6 addresses List: 192.168.1.1-255, 192.168.2.1-100, 192.168.2.200, 192.168.4.0/24 This field supports spaces, tabulation and multiple lines. |

| Parameter | Description |
|---|--|
| <i>Update interval</i> | <p>This parameter defines how often Zabbix will execute the rule.</p> <p>The interval is measured after the execution of previous discovery instance ends so there is no overlap.</p> <p>Time suffixes are supported, e.g. 30s, 1m, 2h, 1d.</p> <p>User macros are supported.</p> <p><i>Note</i> that if a user macro is used and its value is changed (e.g. 1w → 1h), the next check will be executed according to the previous value (far in the future with the example values).</p> |
| <i>Maximum concurrent checks per type</i> | <p>Set the maximum number of discovery threads (workers) per service check for parallel processing of discovery checks:</p> <p>One - one thread</p> <p>Unlimited - unlimited number of threads (but no more than in the StartDiscoverers parameter)</p> <p>Custom - set a custom number of threads (0-999)</p> <p><i>Note</i> that all discovery rules with SNMPv3 asynchronous service checks are processed by one worker due to the peculiarities of libsnmp implementation, i.e. increasing the number of workers will not increase the discovery speed.</p> |
| <i>Checks</i> | <p>Zabbix will use this list of checks for discovery. Click on Add to configure a new check in a popup window.</p> <p>Supported checks: SSH, LDAP, SMTP, FTP, HTTP, HTTPS, POP, NNTP, IMAP, TCP, Telnet, Zabbix agent, SNMPv1 agent, SNMPv2 agent, SNMPv3 agent, ICMP ping.</p> <p>A protocol-based discovery uses the net.tcp.service[] functionality to test each host, except for SNMP which queries an SNMP OID. Zabbix agent is tested by querying an item in unencrypted mode. Please see agent items for more details.</p> <p>The 'Ports' parameter may be one of following:</p> <p>Single port: 22</p> <p>Range of ports: 22-45</p> <p>List: 22-45,55,60-70</p> <p>Since Zabbix 7.0. all service checks are performed asynchronously, except for LDAP checks. Since Zabbix 7.0 HTTP/HTTPS checking is done via libcurl. If Zabbix server/proxy is compiled without libcurl, then HTTP checks will work like in previous versions (i.e. as TCP checks), but HTTPS checks will not work.</p> |
| <i>Device uniqueness criteria</i> | <p>Uniqueness criteria may be:</p> <p>IP address - do not process multiple single-IP devices. If a device with the same IP already exists it will be considered already discovered and a new host will not be added.</p> <p><discovery check> - either Zabbix agent or SNMP agent check.</p> <p><i>Note</i> that uniqueness criteria used during discovery is not the same as host identification in the system when performing actions. Uniqueness criteria during discovery define whether two or more discovered devices are the same (or different), whereas only the IP address is the criterion for host identification in Zabbix (see Host creation).</p> |
| <i>Host name</i> | <p>Set the technical host name of a created host using:</p> <p>DNS name - DNS name (default)</p> <p>IP address - IP address</p> <p><discovery check> - received string value of the discovery check (e.g. Zabbix agent, SNMP agent check)</p> <p>See also: Host naming.</p> |
| <i>Visible name</i> | <p>Set the visible host name of a created host using:</p> <p>Host name - technical host name (default)</p> <p>DNS name - DNS name</p> <p>IP address - IP address</p> <p><discovery check> - received string value of the discovery check (e.g. Zabbix agent, SNMP agent check)</p> <p>See also: Host naming.</p> |
| <i>Enabled</i> | <p>With the check-box marked the rule is active and will be executed by Zabbix server.</p> <p>If unmarked, the rule is not active. It won't be executed.</p> |

Exceeding file descriptor limit

In case of large number of concurrent checks, it is possible to exhaust the file descriptor limit for the **discovery manager**.

The number of file descriptors required for detection equates to the number of discovery workers * 1000. By default, there are 5 **discovery workers**, while the soft limit of the system is approximately 1024.

If this limit is approached, Zabbix will reduce the default number of concurrent checks per type for each worker and write a warning

to the log file. But, if the user has set a higher value for *Maximum concurrent checks per type* than the value calculated by Zabbix, Zabbix will use the user-defined value for one worker.

A real life scenario

In this example, we would like to set up network discovery for the local network having an IP range of 192.168.1.1-192.168.1.254.

In our scenario we want to:

- discover those hosts that have Zabbix agent running
- run discovery every 10 minutes
- add a host to monitoring if the host uptime is more than 1 hour
- remove hosts if the host downtime is more than 24 hours
- add Linux hosts to the "Linux servers" group
- add Windows hosts to the "Windows servers" group
- use the template *Linux* for Linux hosts
- use the template *Windows* for Windows hosts

Step 1

Defining a network discovery rule for our IP range.

New discovery rule

* Name

Local network

Discovery by

ServerProxy

* IP range

192.168.1.1-254

* Update interval

☒ Zabbix agent "system.uname"

Visible name

☒ Host name

☐ DNS name

☐ IP address

☐ Zabbix agent "system.uname"

Enabled

☒

Zabbix will try to discover hosts in the IP range of 192.168.1.1-192.168.1.254 by connecting to Zabbix agents and getting the value from the **system.uname** key. The value received from the agent can be used to name the hosts and also to apply different actions for different operating systems. For example, link Windows servers to the template *Windows*, Linux servers to the template *Linux*.

The rule will be executed every 10 minutes.

When this rule is added, Zabbix will automatically start the discovery and generation of the discovery-based events for further processing.

Step 2

Defining a discovery **action** for adding the discovered Linux servers to the respective group/template.

| Action | Operations | | | | | | | | | | |
|---------------------|---|-------|------|---|--------------------------------------|---|-----------------------------------|---|---|---|--|
| * Name | Add discovered Linux servers | | | | | | | | | | |
| Type of calculation | And A and B and C and D | | | | | | | | | | |
| Conditions | <table><thead><tr><th>Label</th><th>Name</th></tr></thead><tbody><tr><td>A</td><td>Received value contains <i>Linux</i></td></tr><tr><td>B</td><td>Discovery status equals <i>Up</i></td></tr><tr><td>C</td><td>Service type equals <i>Zabbix agent</i></td></tr><tr><td>D</td><td>Uptime/Downtime is greater than or equals 3600</td></tr></tbody></table> Add | Label | Name | A | Received value contains <i>Linux</i> | B | Discovery status equals <i>Up</i> | C | Service type equals <i>Zabbix agent</i> | D | Uptime/Downtime is greater than or equals 3600 |
| Label | Name | | | | | | | | | | |
| A | Received value contains <i>Linux</i> | | | | | | | | | | |
| B | Discovery status equals <i>Up</i> | | | | | | | | | | |
| C | Service type equals <i>Zabbix agent</i> | | | | | | | | | | |
| D | Uptime/Downtime is greater than or equals 3600 | | | | | | | | | | |

The action will be activated if:

- the "Zabbix agent" service is "up"
- the value of system.uname (the Zabbix agent key we used in rule definition) contains "Linux"
- Uptime is 1 hour (3600 seconds) or more

| | |
|-----------------|---|
| Action | Operations |
| Default subject | Discovery: {DISCOVERY.DEVICE.STATUS}, {DISCOVERY.DEVICE.IPADDRESS} |
| Default message | Discovery rule: {DISCOVERY.RULE.NAME} Device IP: {DISCOVERY.DEVICE.IPADDRESS} Device DNS: {DISCOVERY.DEVICE.DNS} Device status: {DISCOVERY.DEVICE.STATUS} Device uptime: {DISCOVERY.DEVICE.UPTIME} Device service name: {DISCOVERY.SERVICE.NAME} |
| Operations | Details Add to host groups: Linux servers Link to templates: Linux Add |

The action will execute the following operations:

- add the discovered host to the "Linux servers" group (and also add host if it wasn't added previously)
- link host to the *Linux* template. Zabbix will automatically start monitoring the host using items and triggers from the "Linux" template.

Step 3

Defining a discovery action for adding the discovered Windows servers to the respective group/template.

| Action | Operations | | | | | | | | | | |
|---------------------|--|-------|------|---|--|---|-----------------------------------|---|---|---|--|
| * Name | Add discovered Windows servers | | | | | | | | | | |
| Type of calculation | <div>And</div> <div>A and B and C and D</div> | | | | | | | | | | |
| Conditions | <table border="1"> <thead> <tr> <th>Label</th> <th>Name</th> </tr> </thead> <tbody> <tr> <td>A</td> <td>Received value contains <i>Windows</i></td> </tr> <tr> <td>B</td> <td>Discovery status equals <i>Up</i></td> </tr> <tr> <td>C</td> <td>Service type equals <i>Zabbix agent</i></td> </tr> <tr> <td>D</td> <td>Uptime/Downtime is greater than or equals 3600</td> </tr> </tbody> </table> Add | Label | Name | A | Received value contains <i>Windows</i> | B | Discovery status equals <i>Up</i> | C | Service type equals <i>Zabbix agent</i> | D | Uptime/Downtime is greater than or equals 3600 |
| Label | Name | | | | | | | | | | |
| A | Received value contains <i>Windows</i> | | | | | | | | | | |
| B | Discovery status equals <i>Up</i> | | | | | | | | | | |
| C | Service type equals <i>Zabbix agent</i> | | | | | | | | | | |
| D | Uptime/Downtime is greater than or equals 3600 | | | | | | | | | | |

| Action | Operations |
|-----------------|---|
| Default subject | Discovery: {DISCOVERY.DEVICE.STATUS}, {DISCOVERY.DEVICE.IPADDRESS} |
| Default message | Discovery rule: {DISCOVERY.RULE.NAME} Device IP: {DISCOVERY.DEVICE.IPADDRESS} Device DNS: {DISCOVERY.DEVICE.DNS} Device status: {DISCOVERY.DEVICE.STATUS} Device uptime: {DISCOVERY.DEVICE.UPTIME} Device service name: {DISCOVERY.SERVICE.NAME} |
| Operations | Details Add to host groups: Windows servers Link to templates: Windows Add |

Step 4

Defining a discovery action for removing lost servers.

| Action | Operations | | | | | | | | |
|---------------------|---|-------|------|---|---|---|------------------------------|---|----------------------------------|
| * Name | Remove lost servers | | | | | | | | |
| Type of calculation | And ▼ A and B and C | | | | | | | | |
| Conditions | <table border="1"> <thead> <tr> <th>Label</th> <th>Name</th> </tr> </thead> <tbody> <tr> <td>A</td> <td>Uptime/Downtime is greater than or equals 86400</td> </tr> <tr> <td>B</td> <td>Discovery status equals Down</td> </tr> <tr> <td>C</td> <td>Service type equals Zabbix agent</td> </tr> </tbody> </table> Add | Label | Name | A | Uptime/Downtime is greater than or equals 86400 | B | Discovery status equals Down | C | Service type equals Zabbix agent |
| Label | Name | | | | | | | | |
| A | Uptime/Downtime is greater than or equals 86400 | | | | | | | | |
| B | Discovery status equals Down | | | | | | | | |
| C | Service type equals Zabbix agent | | | | | | | | |

| Action | Operations | | | | |
|-----------------|---|---------|--------|-------------|---|
| Default subject | Discovery: {DISCOVERY.DEVICE.STATUS}, {DISCOVERY.DEVICE.IPADDRESS} | | | | |
| Default message | Discovery rule: {DISCOVERY.RULE.NAME} Device IP: {DISCOVERY.DEVICE.IPADDRESS} Device DNS: {DISCOVERY.DEVICE.DNS} Device status: {DISCOVERY.DEVICE.STATUS} Device uptime: {DISCOVERY.DEVICE.UPTIME} Device service name: {DISCOVERY.SERVICE.NAME} | | | | |
| Operations | <table border="1"> <thead> <tr> <th>Details</th> <th>Action</th> </tr> </thead> <tbody> <tr> <td>Remove host</td> <td> Edit Remove </td> </tr> </tbody> </table> Add | Details | Action | Remove host | Edit Remove |
| Details | Action | | | | |
| Remove host | Edit Remove | | | | |

A server will be removed if "Zabbix agent" service is 'down' for more than 24 hours (86400 seconds).

2 Active agent autoregistration

Overview

It is possible to allow active Zabbix agent autoregistration, after which the server can start monitoring them. This way new hosts can be added for monitoring without configuring them manually on the server.

Autoregistration can happen when a previously unknown active agent asks for checks.

The feature might be very handy for automatic monitoring of new Cloud nodes. As soon as you have a new node in the Cloud Zabbix will automatically start the collection of performance and availability data of the host.

Active agent autoregistration also supports the monitoring of added hosts with passive checks. When the active agent asks for checks, providing it has the 'ListenIP' or 'ListenPort' configuration parameters defined in the configuration file, these are sent along to the server. (If multiple IP addresses are specified, the first one is sent to the server.)

Server, when adding the new autoregistered host, uses the received IP address and port to configure the agent. If no IP address value is received, the one used for the incoming connection is used. If no port value is received, 10050 is used.

It is possible to specify that the host should be autoregistered with a **DNS name** as the default agent interface.

Autoregistration is rerun:

- if host **metadata** information changes:
 - due to HostMetadata changed and agent restarted
 - due to value returned by HostMetadataItem changed
- for manually created hosts with metadata missing
- if a host is manually changed to be monitored by another Zabbix proxy
- if autoregistration for the same host comes from a new Zabbix proxy

The active agent autoregistration heartbeat for Zabbix server and Zabbix proxy is 120 seconds. So in case a discovered host is deleted, the autoregistration will be rerun in 120 seconds.

Configuration

Specify server

Make sure you have the Zabbix server identified in the agent **configuration file** - `zabbix_agentd.conf`

`ServerActive=10.0.0.1`

Unless you specifically define a *Hostname* in `zabbix_agentd.conf`, the system hostname of agent location will be used by server for naming the host. The system hostname in Linux can be obtained by running the 'hostname' command.

If *Hostname* is defined in Zabbix agent configuration as a comma-delimited list of hosts, hosts will be created for all listed hostnames.

Restart the agent after making any changes to the configuration file.

Action for active agent autoregistration

When server receives an autoregistration request from an agent it calls an **action**. An action of event source "Autoregistration" must be configured for agent autoregistration.

Note:

Setting up **network discovery** is not required to have active agents autoregister.

In the Zabbix frontend, go to *Alerts* → *Actions*, select *Autoregistration actions* and click on *Create action*:

- In the Action tab, give your action a name
- Optionally specify **conditions**. You can do a substring match or regular expression match in the conditions for host name/host metadata. If you are going to use the "Host metadata" condition, see the next section.
- In the Operations tab, add relevant operations, such as - 'Add host', 'Add to host group' (for example, *Discovered hosts*), 'Link templates', etc.

Note:

If the hosts that will be autoregistering are likely to be supported for active monitoring only (such as hosts that are firewalled from your Zabbix server) then you might want to create a specific template like *Template_Linux-active* to link to.

Created hosts are added to the *Discovered hosts* group (by default, configurable in *Administration* → *General* → **Other**). If you wish hosts to be added to another group, add a *Remove from host group* operation (specifying "Discovered hosts") and also add an *Add to host group* operation (specifying another host group), because a host must belong to a host group.

Secure autoregistration

A secure way of autoregistration is possible by configuring PSK-based authentication with encrypted connections.

The level of encryption is configured globally in *Administration* → *General* → **Autoregistration**. It is possible to select no encryption, TLS encryption with PSK authentication or both (so that some hosts may register without encryption while others through encryption).

Authentication by PSK is verified by Zabbix server before adding a host. If successful, the host is added and **Connections from/to host** are set to 'PSK' only with identity/pre-shared key the same as in the global autoregistration setting.

Attention:

To ensure security of autoregistration on installations using proxies, encryption between Zabbix server and proxy should be enabled.

Using DNS as default interface

HostInterface and HostInterfaceItem **configuration parameters** allow to specify a custom value for the host interface during autoregistration.

More specifically, they are useful if the host should be autoregistered with a DNS name as the default agent interface rather than its IP address. In that case the DNS name should be specified or returned as the value of either `HostInterface` or `HostInterfaceItem` parameters. Note that if the value of one of the two parameters changes, the autoregistered host interface is updated. So it is possible to update the default interface to another DNS name or update it to an IP address. For the changes to take effect though, the agent has to be restarted.

Note:

If `HostInterface` or `HostInterfaceItem` parameters are not configured, the `listen_dns` parameter is resolved from the IP address. If such resolving is configured incorrectly, it may break autoregistration because of invalid hostname.

Using host metadata

When agent is sending an autoregistration request to the server it sends its hostname. In some cases (for example, Amazon cloud nodes) a hostname is not enough for Zabbix server to differentiate discovered hosts. Host metadata can be optionally used to send other information from an agent to the server.

Host metadata is configured in the agent **configuration file** - `zabbix_agentd.conf`. There are 2 ways of specifying host metadata in the configuration file:

`HostMetadata`

`HostMetadataItem`

See the description of the options in the link above.

The `HostMetadataItem` parameter may return up to 65535 UTF-8 code points. A longer value will be truncated.

Note that on MySQL, the effective maximum length in characters will be less if the returned value contains multibyte characters. For example, a value containing 3-byte characters only will be limited to 21844 characters in total, while a value containing 4-byte characters only will be limited to 16383 symbols.

Attention:

An autoregistration attempt happens every time an active agent sends a request to refresh active checks to the server. The delay between requests is specified in the **RefreshActiveChecks** parameter of the agent. The first request is sent immediately after the agent is restarted.

Example 1

Using host metadata to distinguish between Linux and Windows hosts.

Say you would like the hosts to be autoregistered by the Zabbix server. You have active Zabbix agents (see "Configuration" section above) on your network. There are Windows hosts and Linux hosts on your network and you have "Linux by Zabbix agent" and "Windows by Zabbix agent" templates available in your Zabbix frontend. So at host registration, you would like the appropriate Linux/Windows template to be applied to the host being registered. By default, only the hostname is sent to the server at autoregistration, which might not be enough. In order to make sure the proper template is applied to the host you should use host metadata.

Frontend configuration

The first thing to do is to configure the frontend. Create 2 actions. The first action:

- Name: Linux host autoregistration
- Conditions: Host metadata contains *Linux*
- Operations: Link templates: Linux

Note:

You can skip an "Add host" operation in this case. Linking a template to a host requires adding the host first so the server will do that automatically.

The second action:

- Name: Windows host autoregistration
- Conditions: Host metadata contains *Windows*
- Operations: Link templates: Windows

Agent configuration

Now you need to configure the agents. Add the next line to the agent configuration files:

```
HostMetadataItem=system.uname
```

This way you make sure host metadata will contain "Linux" or "Windows" depending on the host an agent is running on. An example of host metadata in this case:

Linux: Linux server3 3.2.0-4-686-pae #1 SMP Debian 3.2.41-2 i686 GNU/Linux

Windows: Windows WIN-OPXGGSTYNH0 6.0.6001 Windows Server 2008 Service Pack 1 Intel IA-32

Do not forget to restart the agent after making any changes to the configuration file.

Example 2

Step 1

Using host metadata to allow some basic protection against unwanted hosts registering.

Frontend configuration

Create an action in the frontend, using some hard-to-guess secret code to disallow unwanted hosts:

- Name: Autoregistration action Linux
- Conditions:
 - Type of calculation: AND
 - Condition (A): Host metadata contains //Linux//
 - Condition (B): Host metadata contains //21df83bf21bf0be663090bb8d4128558ab9b95fba66a6dbf834f8b91ae5e08ae//
- Operations:
 - Send message to users: Admin via all media
 - Add to host groups: Linux servers
 - Link templates: Linux

Please note that this method alone does not provide strong protection because data is transmitted in plain text. Configuration cache reload is required for changes to have an immediate effect.

Agent configuration

Add the next line to the agent configuration file:

```
HostMetadata=Linux 21df83bf21bf0be663090bb8d4128558ab9b95fba66a6dbf834f8b91ae5e08ae
```

where "Linux" is a platform, and the rest of the string is the hard-to-guess secret text.

Do not forget to restart the agent after making any changes to the configuration file.

Step 2

It is possible to add additional monitoring for an already registered host.

Frontend configuration

Update the action in the frontend:

- Name: Autoregistration action Linux
- Conditions:
 - Type of calculation: AND
 - Condition (A): Host metadata contains Linux
 - Condition (B): Host metadata contains 21df83bf21bf0be663090bb8d4128558ab9b95fba66a6dbf834f8b91ae5e08ae
- Operations:
 - Send message to users: Admin via all media
 - Add to host groups: Linux servers
 - Link templates: Linux
 - Link templates: MySQL by Zabbix Agent

Agent configuration

Update the next line in the agent configuration file:

```
HostMetadata=MySQL on Linux 21df83bf21bf0be663090bb8d4128558ab9b95fba66a6dbf834f8b91ae5e08ae
```

Do not forget to restart the agent after making any changes to the configuration file.

3 Low-level discovery

Overview Low-level discovery provides a way to automatically create items, triggers, and graphs for different entities on a computer. For instance, Zabbix can automatically start monitoring file systems or network interfaces on your machine, without the need to create items for each file system or network interface manually. Additionally, it is possible to configure Zabbix to remove unneeded entities automatically based on the actual results of periodically performed discovery.

A user can define their own types of discovery, provided they follow a particular JSON protocol.

The general architecture of the discovery process is as follows.

First, a user creates a discovery rule in *Data collection* → *Templates*, in the *Discovery* column. A discovery rule consists of (1) an item that discovers the necessary entities (for instance, file systems or network interfaces) and (2) prototypes of items, triggers, and graphs that should be created based on the value of that item.

An item that discovers the necessary entities is like a regular item seen elsewhere: the server asks a Zabbix agent (or whatever the type of the item is set to) for a value of that item, the agent responds with a textual value. The difference is that the value the agent responds with should contain a list of discovered entities in a JSON format. While the details of this format are only important for implementers of custom discovery checks, it is necessary to know that the returned value contains a list of macro → value pairs. For instance, item "net.if.discovery" might return two pairs: "{#IFNAME}" → "lo" and "{#IFNAME}" → "eth0".

These macros are used in names, keys and other prototype fields where they are then substituted with the received values for creating real items, triggers, graphs or even hosts for each discovered entity. See the full list of [options](#) for using LLD macros.

When the server receives a value for a discovery item, it looks at the macro → value pairs and for each pair generates real items, triggers, and graphs, based on their prototypes. In the example with "net.if.discovery" above, the server would generate one set of items, triggers, and graphs for the loopback interface "lo", and another set for interface "eth0".

Note that since **Zabbix 4.2**, the format of the JSON returned by low-level discovery rules has been changed. It is no longer expected that the JSON will contain the "data" object. Low-level discovery will now accept a normal JSON containing an array, in order to support new features such as the item value preprocessing and custom paths to low-level discovery macro values in a JSON document.

Built-in discovery keys have been updated to return an array of LLD rows at the root of JSON document. Zabbix will automatically extract a macro and value if an array field uses the {#MACRO} syntax as a key. Any new native discovery checks will use the new syntax without the "data" elements. When processing a low-level discovery value first the root is located (array at \$. or \$.data).

While the "data" element has been removed from all native items related to discovery, for backward compatibility Zabbix will still accept the JSON notation with a "data" element, though its use is discouraged. If the JSON contains an object with only one "data" array element, then it will automatically extract the content of the element using JSONPath \$.data. Low-level discovery now accepts optional user-defined LLD macros with a custom path specified in JSONPath syntax.

Warning:

As a result of the changes above, newer agents no longer will be able to work with an older Zabbix server.

See also: [Discovered entities](#)

Configuring low-level discovery We will illustrate low-level discovery based on an example of file system discovery.

To configure the discovery, do the following:

- Go to: *Data collection* → *Templates* or *Hosts*
- Click on *Discovery* in the row of an appropriate template/host

Templates

| <input type="checkbox"/> | Name ▲ | Hosts | Items | Triggers | Graphs | Dashboards | Discovery |
|--------------------------|----------------|-------|----------|-------------|----------|--------------|-------------|
| <input type="checkbox"/> | Linux OS agent | Hosts | Items 43 | Triggers 15 | Graphs 8 | Dashboards 3 | Discovery 3 |

- Click on *Create discovery rule* in the upper right corner of the screen
- Fill in the discovery rule form with the required details

Discovery rule

The discovery rule form contains five tabs, representing, from left to right, the data flow during discovery:

- *Discovery rule* - specifies, most importantly, the built-in item or custom script to retrieve discovery data
- *Preprocessing* - applies some preprocessing to the discovered data
- *LLD macros* - allows to extract some macro values to use in discovered items, triggers, etc

- *Filters* - allows to filter the discovered values
- *Overrides* - allows to modify items, triggers, graphs or host prototypes when applying to specific discovered objects

The **Discovery rule** tab contains the item key to use for discovery (as well as some general discovery rule attributes):

Discovery rule

All mandatory input fields are marked with a red asterisk.

| Parameter | Description |
|------------------------|---|
| <i>Name</i> | Name of discovery rule. |
| <i>Type</i> | The type of check to perform discovery. In this example we are using a <i>Zabbix agent</i> item type. The discovery rule can also be a dependent item , depending on a regular item. It cannot depend on another discovery rule. For a dependent item, select the respective type (<i>Dependent item</i>) and specify the master item in the 'Master item' field. The master item must exist. |
| <i>Key</i> | Enter the discovery item key (up to 2048 characters). For example, you may use the built-in "vfs.fs.discovery" item key to return a JSON string with the list of file systems present on the computer, their types and mount options. Note that another option for filesystem discovery is using discovery results by the "vfs.fs.get" agent key (see example). |
| <i>Update interval</i> | This field specifies how often Zabbix performs discovery. In the beginning, when you are just setting up file system discovery, you might wish to set it to a small interval, but once you know it works you can set it to 30 minutes or more, because file systems usually do not change very often. Time suffixes are supported, e.g. 30s, 1m, 2h, 1d. User macros are supported. <i>Note:</i> The update interval can only be set to '0' if custom intervals exist with a non-zero value. If set to '0', and a custom interval (flexible or scheduled) exists with a non-zero value, the item will be polled during the custom interval duration. New discovery rules will be checked within 60 seconds of their creation, unless they have Scheduling or Flexible update interval and the <i>Update interval</i> is set to 0. <i>Note</i> that for an existing discovery rule the discovery can be performed immediately by pushing the <i>Execute now</i> button . |

| Parameter | Description |
|-------------------------------|--|
| <i>Custom intervals</i> | <p>You can create custom rules for checking the item:</p> <p>Flexible - create an exception to the <i>Update interval</i> (interval with different frequency)</p> <p>Scheduling - create a custom polling schedule.</p> <p>For detailed information see Custom intervals.</p> |
| <i>Timeout</i> | <p>Set the discovery check timeout. Select the timeout option:</p> <p>Global - proxy/global timeout is used (displayed in the grayed out <i>Timeout</i> field);</p> <p>Override - custom timeout is used (set in the <i>Timeout</i> field; allowed range: 1 - 600s). Time suffixes, e.g. 30s, 1m, and user macros are supported.</p> <p>Clicking the <i>Timeouts</i> link allows you to configure proxy timeouts or global timeouts (if a proxy is not used). Note that the <i>Timeouts</i> link is visible only to users of <i>Super admin</i> type with permissions to <i>Administration</i> → General or <i>Administration</i> → Proxies frontend sections.</p> |
| <i>Delete lost resources</i> | <p>Specify how soon the discovered entity will be deleted once its discovery status becomes "Not discovered anymore":</p> <p>Never - it will not be deleted;</p> <p>Immediately - it will be deleted immediately;</p> <p>After - it will be deleted after the specified time period. The value must be greater than <i>Disable lost resources</i> value.</p> <p>Time suffixes are supported, e.g. 2h, 1d.</p> <p>User macros are supported.</p> <p>Note: Using "Immediately" is not recommended, since just wrongly editing the filter may end up in the entity being deleted with all the historical data.</p> |
| <i>Disable lost resources</i> | <p>Note that manually disabled resources will not be deleted by low-level discovery.</p> <p>Specify how soon the discovered entity will be disabled once its discovery status becomes "Not discovered anymore":</p> <p>Never - it will not be disabled;</p> <p>Immediately - it will be disabled immediately;</p> <p>After - it will be disabled after the specified time period. The value should be greater than the discovery rule update interval.</p> <p>Note that automatically disabled resources will become enabled again, if re-discovered by low-level discovery. Manually disabled resources will not become enabled again if re-discovered.</p> <p>This field is not displayed if <i>Delete lost resources</i> is set to "Immediately".</p> <p>Time suffixes are supported, e.g. 2h, 1d.</p> <p>User macros are supported.</p> |
| <i>Description</i> | Enter a description. |
| <i>Enabled</i> | If checked, the rule will be processed. |

Note:

Discovery rule history is not preserved.

Preprocessing

The **Preprocessing** tab allows to define transformation rules to apply to the result of discovery. One or several transformations are possible in this step. Transformations are executed in the order in which they are defined. All preprocessing is done by Zabbix server.

- [Preprocessing details](#)
- [Preprocessing testing](#)

Preprocessing steps

Name

Parameters

1:

Regular expression

pattern

2:

JSONPath

\$.pool

Add

Type

Transformation

Description

Text

Regular expression

Match the received value to the `<pattern>` regular expression and replace value with the extracted `<output>`. The regular expression supports extraction of maximum 10 captured groups with the `\N` sequence.

Parameters:

pattern - regular expression

output - output formatting template. An `\N` (where `N=1...9`) escape sequence is replaced with the `N`th matched group. A `\0` escape sequence is replaced with the matched text.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.

Replace

Find the search string and replace it with another (or nothing). All occurrences of the search string will be replaced.

Parameters:

search string - the string to find and replace, case-sensitive (required)

replacement - the string to replace the search string with. The replacement string may also be empty effectively allowing to delete the search string when found.

It is possible to use escape sequences to search for or replace line breaks, carriage return, tabs and spaces `"\n \r \t \s"`; backslash can be escaped as `"\\"` and escape sequences can be escaped as `"\\n"`. Escaping of line breaks, carriage return, tabs is automatically done during low-level discovery.

Structured

data

JSONPath

Extract value or fragment from JSON data using [JSONPath functionality](#).

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.

XML XPath

Extract value or fragment from XML data using XPath functionality.

For this option to work, Zabbix server must be compiled with libxml support.

Examples:

`number(/document/item/value)` will extract 10 from

```
<document><item><value>10</value></item></document>
```

`number(/document/item/@attribute)` will extract 10 from `<document><item attribute="10"></item></document>`

`/document/item` will extract `<item><value>10</value></item>` from

```
<document><item><value>10</value></item></document>
```

Note that namespaces are not supported.

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.

CSV to JSON

Convert CSV file data into JSON format.

For more information, see: [CSV to JSON preprocessing](#).

XML to JSON

Convert data in XML format to JSON.

For more information, see: [Serialization rules](#).

If you mark the *Custom on fail* checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.

SNMP

| Type | |
|--|---|
| <i>SNMP walk value</i> | <p>Extract value by the specified OID/MIB name and apply formatting options:</p> <p>Unchanged - return Hex-STRING as unescaped hex string (<i>note</i> that display hints are still applied);</p> <p>UTF-8 from Hex-STRING - convert Hex-STRING to UTF-8 string;</p> <p>MAC from Hex-STRING - convert Hex-STRING to MAC address string (which will have ' ' replaced by ':');</p> <p>Integer from BITS - convert the first 8 bytes of a bit string expressed as a sequence of hex characters (e.g. "1A 2B 3C 4D") into a 64-bit unsigned integer. In bit strings longer than 8 bytes, consequent bytes will be ignored.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| <i>SNMP walk to JSON</i> | <p>Convert SNMP values to JSON. Specify a field name in the JSON and the corresponding SNMP OID path. Field values will be populated by values in the specified SNMP OID path.</p> <p>You may use this preprocessing step for SNMP OID discovery.</p> <p>Similar value formatting options as in the <i>SNMP walk value</i> step are available.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| <i>SNMP get value</i> | <p>Apply formatting options to the SNMP get value:</p> <p>UTF-8 from Hex-STRING - convert Hex-STRING to UTF-8 string;</p> <p>MAC from Hex-STRING - convert Hex-STRING to MAC address string (which will have ' ' replaced by ':');</p> <p>Integer from BITS - convert the first 8 bytes of a bit string expressed as a sequence of hex characters (e.g. "1A 2B 3C 4D") into a 64-bit unsigned integer. In bit strings longer than 8 bytes, consequent bytes will be ignored.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| Custom scripts | |
| <i>JavaScript</i> | <p>Enter JavaScript code in the modal editor that opens when clicking in the parameter field or on the pencil icon next to it.</p> <p>Note that available JavaScript length depends on the database used.</p> <p>For more information, see: Javascript preprocessing</p> |
| Validation | |
| <i>Does not match regular expression</i> | <p>Specify a regular expression that a value must not match.</p> <p>E.g. Error: (.*)\.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| <i>Check for error in JSON</i> | <p>Check for an application-level error message located at JSONPath. Stop processing if succeeded and message is not empty; otherwise continue processing with the value that was before this preprocessing step. Note that these external service errors are reported to user as is, without adding preprocessing step information.</p> <p>E.g. \$.errors. If a JSON like {"errors": "e1"} is received, the next preprocessing step will not be executed.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| <i>Check for error in XML</i> | <p>Check for an application-level error message located at Xpath. Stop processing if succeeded and message is not empty; otherwise continue processing with the value that was before this preprocessing step. Note that these external service errors are reported to user as is, without adding preprocessing step information.</p> <p>No error will be reported in case of failing to parse invalid XML.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| <i>Matches regular expression</i> | <p>Specify a regular expression that a value must match.</p> <p>If you mark the <i>Custom on fail</i> checkbox, it is possible to specify custom error-handling options: either to discard the value, set a specified value or set a specified error message.</p> |
| Throttling | |

| Type | |
|---|--|
| <i>Discard unchanged with heartbeat</i> | <p>Discard a value if it has not changed within the defined time period (in seconds). Positive integer values are supported to specify the seconds (minimum - 1 second). Time suffixes can be used in this field (e.g. 30s, 1m, 2h, 1d). User macros and low-level discovery macros can be used in this field.</p> <p>Only one throttling option can be specified for a discovery item.</p> <p>E.g. 1m. If identical text is passed into this rule twice within 60 seconds, it will be discarded.</p> <p><i>Note:</i> Changing item prototypes does not reset throttling. Throttling is reset only when preprocessing steps are changed.</p> |
| Prometheus | |
| <i>Prometheus to JSON</i> | <p>Convert required Prometheus metrics to JSON.</p> <p>See Prometheus checks for more details.</p> |

Note that if the discovery rule has been applied to the host via template then the content of this tab is read-only.

Custom macros

The **LLD macros** tab allows to specify custom low-level discovery macros.

Custom macros are useful in cases when the returned JSON does not have the required macros already defined. So, for example:

- The native `vfs.fs.discovery` key for filesystem discovery returns a JSON with some pre-defined LLD macros such as `{#FSNAME}`, `{#FSTYPE}`. These macros can be used in item, trigger prototypes (see subsequent sections of the page) directly; defining custom macros is not needed;
- The `vfs.fs.get` agent item also returns a JSON with [filesystem data](#), but without any pre-defined LLD macros. In this case you may define the macros yourself, and map them to the values in the JSON using JSONPath:

Discovery rule
Preprocessing
LLD macros 2
Filters
Overrides

LLD macros

| LLD macro | JSONPath |
|------------------------|------------------------|
| <code>{#FSNAME}</code> | <code>\$.fsname</code> |
| <code>{#FSTYPE}</code> | <code>\$.fstype</code> |

Add

The extracted values can be used in discovered items, triggers, etc. Note that values will be extracted from the result of discovery and any preprocessing steps so far.

| Parameter | Description |
|------------------|---|
| <i>LLD macro</i> | Name of the low-level discovery macro, using the following syntax: <code>{#MACRO}</code> . |
| <i>JSONPath</i> | <p>Path that is used to extract LLD macro value from an LLD row, using JSONPath syntax.</p> <p>The values extracted from the returned JSON are used to replace the LLD macros in item, trigger, etc. prototype fields.</p> <p>JSONPath can be specified using the dot notation or the bracket notation. Bracket notation should be used in case of any special characters and Unicode, like <code>\$['unicode + special chars #1']['unicode + special chars #2']</code>.</p> <p>For example, <code>\$.foo</code> will extract "bar" and "baz" from this JSON: <code>[{"foo": "bar"}, {"foo": "baz"}]</code></p> <p>Note that <code>\$.foo</code> will extract "bar" and "baz" also from this JSON: <code>{"data": [{"foo": "bar"}, {"foo": "baz"}]}</code> because a single "data" object is processed automatically (for backwards compatibility with the low-level discovery implementation in Zabbix versions before 4.2).</p> |

Filter

A filter can be used to generate real items, triggers, and graphs only for entities that match the criteria. The **Filters** tab contains discovery rule filter definitions allowing to filter discovery values:

Type of calculation And (A and B) and (C and D)

Filters

| Label | Macro | | Regular expression |
|-------|----------|----------------|-----------------------------|
| A | {FSNAME} | matches | {VFS.FS.FSNAME.MATCHES} |
| B | {FSNAME} | does not match | {VFS.FS.FSNAME.NOT_MATCHES} |
| C | {FSTYPE} | matches | {VFS.FS.FSTYPE.MATCHES} |
| D | {FSTYPE} | does not match | {VFS.FS.FSTYPE.NOT_MATCHES} |

Add

| Parameter | Description |
|---------------------|---|
| Type of calculation | <p>The following options for calculating filters are available:</p> <p>And - all filters must be passed;</p> <p>Or - enough if one filter is passed;</p> <p>And/Or - uses <i>And</i> with different macro names and <i>Or</i> with the same macro name;</p> <p>Custom expression - offers the possibility to define a custom calculation of filters. The formula must include all filters in the list. Limited to 255 symbols.</p> |
| Filters | <p>The following filter condition operators are available: <i>matches</i>, <i>does not match</i>, <i>exists</i>, <i>does not exist</i>.</p> <p><i>Matches</i> and <i>does not match</i> operators expect a Perl Compatible Regular Expression (PCRE). For instance, if you are only interested in C:, D:, and E: file systems, you could put {#FSNAME} into "Macro" and "^C ^D ^E" regular expression into "Regular expression" text fields. Filtering is also possible by file system types using {#FSTYPE} macro (e.g. "^ext ^reiserfs") and by drive types (supported only by Windows agent) using {#FSDRIVETYPE} macro (e.g., "fixed"). You can enter a regular expression or reference a global regular expression in "Regular expression" field.</p> <p>In order to test a regular expression you can use "grep -E", for example: <code>for f in ext2 nfs reiserfs smbfs; do echo \$f grep -E '^ext ^reiserfs' echo "SKIP: \$f"; done</code></p> <p><i>Exists</i> and <i>does not exist</i> operators allow to filter entities based on the presence or absence of the specified LLD macro in the response.</p> <p>Note that if a macro from the filter is missing in the response, the found entity will be ignored, unless a "does not exist" condition is specified for this macro.</p> <p>A warning will be displayed, if the absence of a macro affects the expression result. For example, if {#B} is missing in:</p> <p>{#A} matches 1 and {#B} matches 2 - will give a warning</p> <p>{#A} matches 1 or {#B} matches 2 - no warning</p> |

Warning:

A mistake or a typo in the regular expression used in the LLD rule (for example, an incorrect "File systems for discovery" regular expression) may cause deletion of thousands of configuration elements, historical values, and events for many hosts.

Attention:

Zabbix database in MySQL must be created as case-sensitive if file system names that differ only by case are to be discovered correctly.

Override

The **Override** tab allows setting rules to modify the list of item, trigger, graph and host prototypes or their attributes for discovered objects that meet given criteria.

Discovery rule
Preprocessing
LLD macros
Filters
Overrides 1

Overrides

| Name | Stop processing | Action |
|--------------------------------------|-----------------|------------------------|
| 1: Set trigger with threshold of 50% | Yes | Remove |

Add

Overrides (if any) are displayed in a reorderable drag-and-drop list and executed in the order in which they are defined. To configure details of a new override, click on [Add](#) in the *Overrides* block. To edit an existing override, click on the override name. A popup window will open allowing to edit the override rule details.

Override

* Name

Set trigger with threshold of 50%

If filter matches

Continue overrides

Stop processing

Filters

| Label | Macro | | Regular expression |
|-------|-----------|---------|--------------------|
| A | {#FSNAME} | matches | ^Vtmp\$ |

Add

Operations

Condition

Trigger prototype does not equal *Disk space is low (used > 50%)*

Add

All mandatory parameters are marked with red asterisks.

| Parameter | Description |
|--------------------------|--|
| <i>Name</i> | A unique (per LLD rule) override name. |
| <i>If filter matches</i> | Defines whether next overrides should be processed when filter conditions are met: Continue overrides - subsequent overrides will be processed. Stop processing - operations from preceding (if any) and this override will be executed, subsequent overrides will be ignored for matched LLD rows. |
| <i>Filters</i> | Determines to which discovered entities the override should be applied. Override filters are processed after discovery rule filters and have the same functionality. |
| <i>Operations</i> | Override operations are displayed with these details: Condition - an object type (item prototype/trigger prototype/graph prototype/host prototype) and a condition to be met (equals/does not equal/contains/does not contain/matches/does not match) Actions - links for editing and removing an operation are displayed. |

Configuring an operation

To configure details of a new operation, click on [Add](#) in the Operations block. To edit an existing operation, click on [Edit](#) next to the operation. A popup window where you can edit the operation details will open.

New operation

Object Trigger prototype

Condition does not equal Disk space is low (used > 50%)

Create enabled ☐ Original

Discover ☒ Yes No

Severity ☐ Original

Tags ☐ Original

Add

| Parameter | Description |
|---|---|
| <i>Object</i> | Four types of objects are available: Item prototype Trigger prototype Graph prototype Host prototype |
| <i>Condition</i> | Allows filtering entities to which the operation should be applied. |
| <i>Operator</i> | Supported operators: equals - apply to this prototype does not equal - apply to all prototypes, except this contains - apply, if prototype name contains this string does not contain - apply, if prototype name does not contain this string matches - apply, if prototype name matches regular expression does not match - apply, if prototype name does not match regular expression |
| <i>Pattern</i> | A regular expression or a string to search for. |
| <i>Object:</i> <i>Item</i> <i>pro-</i> <i>to-</i> <i>type</i> | |
| <i>Create enabled</i> | When the checkbox is marked, the buttons will appear, allowing to override original item prototype settings: <i>Yes</i> - the item will be added in an enabled state. <i>No</i> - the item will be added to a discovered entity but in a disabled state. |
| <i>Discover</i> | When the checkbox is marked, the buttons will appear, allowing to override original item prototype settings: <i>Yes</i> - the item will be added. <i>No</i> - the item will not be added. |
| <i>Update interval</i> | When the checkbox is marked, two options will appear, allowing to set different interval for the item: <i>Delay</i> - Item update interval. User macros and time suffixes (e.g. 30s, 1m, 2h, 1d) are supported. Should be set to 0 if <i>Custom interval</i> is used. <i>Custom interval</i> - click Add to specify flexible/scheduling intervals. For detailed information see Custom intervals . |
| <i>History</i> | When the checkbox is marked, the buttons will appear, allowing different history storage period to be set for the item: <i>Do not store</i> - if selected, the history will not be stored. <i>Store up to</i> - if selected, an input field for specifying storage period will appear to the right. User macros and LLD macros are supported. |

| Parameter | Description |
|-------------------------------------|--|
| <i>Trends</i> | When the checkbox is marked, the buttons will appear, allowing different trend storage period to be set for the item: <i>Do not store</i> - if selected, the trends will not be stored. <i>Store up to</i> - if selected, an input field for specifying storage period will appear to the right. User macros and LLD macros are supported. |
| <i>Tags</i> | When the checkbox is marked, a new block will appear, allowing to specify tag-value pairs. These tags will be appended to the tags specified in the item prototype, even if the tag names match. |
| Object: <i>Trigger prototype</i> | |
| <i>Create enabled</i> | When the checkbox is marked, the buttons will appear, allowing to override original trigger prototype settings: <i>Yes</i> - the trigger will be added in an enabled state. <i>No</i> - the trigger will be added to a discovered entity, but in a disabled state. |
| <i>Discover</i> | When the checkbox is marked, the buttons will appear, allowing to override original trigger prototype settings: <i>Yes</i> - the trigger will be added. <i>No</i> - the trigger will not be added. |
| <i>Severity</i> | When the checkbox is marked, trigger severity buttons will appear, allowing to modify trigger severity. |
| <i>Tags</i> | When the checkbox is marked, a new block will appear, allowing to specify tag-value pairs. These tags will be appended to the tags specified in the trigger prototype, even if the tag names match. |
| Object: <i>Graph prototype</i> | |
| <i>Discover</i> | When the checkbox is marked, the buttons will appear, allowing to override original graph prototype settings: <i>Yes</i> - the graph will be added. <i>No</i> - the graph will not be added. |
| Object: <i>Host prototype</i> | |
| <i>Create enabled</i> | When the checkbox is marked, the buttons will appear, allowing to override original host prototype settings: <i>Yes</i> - the host will be created in an enabled state. <i>No</i> - the host will be created in a disabled state. |
| <i>Discover</i> | When the checkbox is marked, the buttons will appear, allowing to override original host prototype settings: <i>Yes</i> - the host will be discovered. <i>No</i> - the host will not be discovered. |
| <i>Link templates</i> | When the checkbox is marked, an input field for specifying templates will appear. Start typing the template name or click on <i>Select</i> next to the field and select templates from the list in a popup window. All templates linked to a host prototype will be replaced by templates from this override. |
| <i>Tags</i> | When the checkbox is marked, a new block will appear, allowing to specify tag-value pairs. These tags will be appended to the tags specified in the host prototype, even if the tag names match. |

| Parameter | Description |
|-----------------------|--|
| <i>Host inventory</i> | When the checkbox is marked, the buttons will appear, allowing to select different inventory mode for the host prototype: <i>Disabled</i> - do not populate host inventory <i>Manual</i> - provide details manually <i>Automated</i> - auto-fill host inventory data based on collected metrics. |

Form buttons

Buttons at the bottom of the form allow to perform several operations.

| | |
|--------------------|---|
| Add | Add a discovery rule. This button is only available for new discovery rules. |
| Update | Update the properties of a discovery rule. This button is only available for existing discovery rules. |
| Clone | Create another discovery rule based on the properties of the current discovery rule. |
| Execute now | Perform discovery based on the discovery rule immediately. The discovery rule must already exist. See more details . Note that when performing discovery immediately, configuration cache is not updated, thus the result will not reflect very recent changes to discovery rule configuration. |
| Test | Test the discovery rule configuration. Use this button to verify the configuration settings (such as connectivity and parameter correctness) without permanently applying any changes. |
| Delete | Delete the discovery rule. |
| Cancel | Cancel the editing of discovery rule properties. |

Discovered entities The screenshots below illustrate how discovered items, triggers, and graphs look like in the host’s configuration. Discovered entities are prefixed with an orange link to a discovery rule they come from.

Items

| All hosts / Zabbix server Enabled ZBX SNMP IPMI JMX Items 140 Triggers 77 Graphs 14 Discovery rules 6 Web scenarios | | | | |
|---|---|------------|---------------------------------|----------|
| <input type="checkbox"/> | Name ▲ | Triggers | Key | Interval |
| <input type="checkbox"/> | ... Mounted filesystem discovery: Get filesystems : FS [/]: Get data | | vfs.fs.dependent[/,data] | |
| <input type="checkbox"/> | ... Mounted filesystem discovery: FS [/]: Get data : FS [/]: Inodes: Free, in % | Triggers 2 | vfs.fs.dependent.inode[/,pfree] | |
| <input type="checkbox"/> | ... Mounted filesystem discovery: FS [/]: Get data : FS [/]: Option: Read-only | Triggers 1 | vfs.fs.dependent[/,readonly] | |
| <input type="checkbox"/> | ... Mounted filesystem discovery: FS [/]: Get data : FS [/]: Space: Available | | vfs.fs.dependent.size[/,free] | |
| <input type="checkbox"/> | ... Mounted filesystem discovery: FS [/]: Get data : FS [/]: Space: Total | | vfs.fs.dependent.size[/,total] | |
| <input type="checkbox"/> | ... Mounted filesystem discovery: FS [/]: Get data : FS [/]: Space: Used | | vfs.fs.dependent.size[/,used] | |
| <input type="checkbox"/> | ... Mounted filesystem discovery: FS [/]: Get data : FS [/]: Space: Used, in % | Triggers 2 | vfs.fs.dependent.size[/,pused] | |

Note that discovered entities will not be created in case there are already existing entities with the same uniqueness criteria, for example, an item with the same key or graph with the same name. An error message is displayed in this case in the frontend that the low-level discovery rule could not create certain entities. The discovery rule itself, however, will not turn unsupported because some entity could not be created and had to be skipped. The discovery rule will go on creating/updating other entities.

If a discovered entity (host, file system, interface, etc) stops being discovered (or does not pass the filter anymore) the entities that were created based on it may be automatically disabled and eventually deleted.

Lost resources may be automatically disabled based on the value of the *Disable lost resources* parameter. This affects lost hosts, items and triggers.

Lost resources may be automatically deleted based on the value of the *Delete lost resources* parameter. This affects lost hosts, host groups, items, triggers, and graphs.

When discovered entities become 'Not discovered anymore', a lifetime indicator is displayed in the entity list. Move your mouse pointer over it and a message will be displayed indicating its status details.

If entities were marked for deletion, but were not deleted at the expected time (disabled discovery rule or item host), they will be deleted the next time the discovery rule is processed.

Entities containing other entities, which are marked for deletion, will not update if changed on the discovery rule level. For example, LLD-based triggers will not update if they contain items that are marked for deletion.

Triggers

| All hosts / Zabbix server | | Enabled | ZBX | SNMP | IPMI | JMX | Items 140 | Triggers 77 | Graphs 14 | Discovery rules 6 |
|---------------------------|----------|---------|---|------|--|-----|-----------|-------------|-----------|-------------------|
| <input type="checkbox"/> | Severity | Value | Name ▲ | | Operational data | | | | | |
| <input type="checkbox"/> | Warning | OK | Mounted filesystem discovery: Linux: FS [/]: Running out of free inodes | | Free inodes: {ITEM.LASTVALUE1} | | | | | |
| | | | Depends on: | | Zabbix server: Linux: FS [/]: Running out of free inodes | | | | | |

| <input type="checkbox"/> | Name ▲ | | | | | | | | | |
| <input type="checkbox"/> | Mounted filesystem discovery: FS [ext4(/)]: Space usage graph, in % (relative to max available) | | | | | | | | | |
| <input type="checkbox"/> | Mounted filesystem discovery: FS [ext4(/)]: Space utilization chart (relative to total) | | | | | | | | | |
| <input type="checkbox"/> | Mounted filesystem discovery: FS [ext4(/var/snap/firefox/common/host-hunspell)]: Space usage graph, in % (relative to max available) | | | | | | | | | |
| <input type="checkbox"/> | Mounted filesystem discovery: FS [ext4(/var/snap/firefox/common/host-hunspell)]: Space utilization chart (relative to total) | | | | | | | | | |

Other types of discovery More detail and how-tos on other types of out-of-the-box discovery is available in the following sections:

- discovery of **network interfaces**;
- discovery of **CPUs and CPU cores**;
- discovery of **SNMP OIDs**;
- discovery of **JMX objects**;
- discovery using **ODBC SQL queries**;
- discovery of **Windows services**;
- discovery of **host interfaces** in Zabbix.

For more detail on the JSON format for discovery items and an example of how to implement your own file system discoverer as a Perl script, see [creating custom LLD rules](#).

1 Item prototypes

Once a rule is created, go to the items for that rule and press "Create item prototype" to create an item prototype.

Note how the `{#FSNAME}` macro is used where a file system name is required. The use of a low-level discovery macro is mandatory in the item key to make sure that the discovery is processed correctly. When the discovery rule is processed, this macro will be substituted with the discovered file system.

Low-level discovery **macros** and user **macros** are supported in item prototype configuration and item value preprocessing **parameters**. Note that when used in update intervals, a single macro has to fill the whole field. Multiple macros in one field or macros mixed with text are not supported.

Note:

Context-specific escaping of low-level discovery macros is performed for safe use in regular expression and XPath preprocessing parameters.

Attributes that are specific for item prototypes:

| Parameter | Description |
|----------------|--|
| Create enabled | If checked the item will be added in an enabled state. If unchecked, the item will be added to a discovered entity, but in a disabled state. |
| Discover | If checked (default) the item will be added to a discovered entity. If unchecked, the item will not be added to a discovered entity, unless this setting is overridden in the discovery rule. |

We can create several item prototypes for each file system metric we are interested in:

≡ Item prototypes

All templates / Template Module Windows filesystem... Discovery list / Mounted filesystem discovery

Item prototypes 3 Trigger prototypes 2 Graph prototypes 1 Host prototypes

| <input type="checkbox"/> | Name ▲ | Key | Interval |
|--------------------------|--|------------------------------|----------|
| <input type="checkbox"/> | ... {#FSNAME}: Space utilization | vfs.fs.size[{#FSNAME},pused] | 1m |
| <input type="checkbox"/> | ... {#FSNAME}: Total space | vfs.fs.size[{#FSNAME},total] | 1m |
| <input type="checkbox"/> | ... {#FSNAME}: Used space | vfs.fs.size[{#FSNAME},used] | 1m |

0 selected

Click on the three-dot icon to open the menu for the specific item prototype with these options:

- *Create trigger prototype* - create a trigger prototype based on this item prototype
- *Trigger prototypes* - click to see a list with links to already-configured trigger prototypes of this item prototype
- *Create dependent item* - create a dependent item for this item prototype

Mass update option is available if you want to update properties of several item prototypes at once.

2 Trigger prototypes

We create trigger prototypes in a similar way as item prototypes:

Attributes that are specific for trigger prototypes:

| Parameter | Description |
|-----------------------|---|
| <i>Create enabled</i> | If checked the trigger will be added in an enabled state. |
| <i>Discover</i> | If unchecked, the trigger will be added to a discovered entity, but in a disabled state. |
| | If checked (default) the trigger will be added to a discovered entity. |
| | If unchecked, the trigger will not be added to a discovered entity, unless this setting is overridden in the discovery rule. |

When real triggers are created from the prototypes, there may be a need to be flexible as to what constant ('20' in our example) is used for comparison in the expression. See how **user macros with context** can be useful to accomplish such flexibility.

You can define **dependencies** between trigger prototypes. To do that, go to the *Dependencies* tab. A trigger prototype may depend on another trigger prototype from the same low-level discovery (LLD) rule or on a regular trigger. A trigger prototype may not depend on a trigger prototype from a different LLD rule or on a trigger created from trigger prototype. Host trigger prototype cannot depend on a trigger from a template.

4 Host prototypes

Host prototypes are blueprints for creating hosts through **low-level discovery** rules. Before being discovered as hosts, these prototypes cannot have items and triggers, except those linked from templates.

Configuration

Host prototypes are configured under **low-level discovery rules**.

To create a host prototype:

1. Go to **Data collection** → **Hosts**.
2. Click **Discovery** for the required host to navigate to the list of low-level discovery rules configured for that host.
3. Click **Host prototypes** for the required discovery rule.
4. Click the **Create host prototype** button in the upper right corner.

Host prototypes have the same parameters as regular **hosts**; however, the following parameters support different or additional configuration:

| Parameter | Description |
|---------------------|--|
| <i>Host name</i> | This parameter must contain at least one low-level discovery macro to ensure unique host names for created hosts. |
| <i>Visible name</i> | Low-level discovery macros are supported. |

| Parameter | Description |
|-------------------------|--|
| <i>Group prototypes</i> | Allows specifying host group prototypes by using low-level discovery macros . Based on the specified group prototypes, host groups will be discovered, created and linked to the created hosts; discovered groups that have already been created by other low-level discovery rules will also be linked to the created hosts. However, discovered host groups that match manually created host groups will not be linked to the created hosts. |
| <i>Interfaces</i> | Set whether discovered hosts inherit the IP from the host that the discovery rule belongs to (default), or get custom interfaces . Low-level discovery macros and user macros are supported. |
| <i>Create enabled</i> | Set the status of discovered hosts; if unchecked, hosts will be created as disabled. |
| <i>Discover</i> | Set whether hosts will be created from the host prototype; if unchecked, hosts will not be created from the host prototype (unless this setting is overridden in the low-level discovery rule). |

Note:

Low-level discovery macros are also supported for tag values and host prototype user macro values.
 Value maps are not supported for host prototypes.

For an example of how to configure a host prototype, see *Virtual machine monitoring*.

Host interfaces

To add custom interfaces, switch the *Interface* selector from "Inherit" to "Custom". Click [Add](#) and select the interface type - Zabbix agent, SNMP, JMX, IPMI.

Note:

If *Custom* is selected, but no interfaces have been set, the hosts will be created without interfaces.
 If *Inherit* is selected and the host prototype belongs to a template, all discovered hosts will inherit the host interface from the host to which the template is linked.

If multiple custom interfaces are specified, the primary interface can be set in the *Default* column.

For an example of how to configure a custom host interface, see *VMware monitoring setup example*.

Warning:

A host will only be created if a host interface contains correct data.

Discovered hosts

In the host list, discovered hosts are prefixed with the name of the discovery rule that created them.

Discovered hosts inherit most parameters from host prototypes as *read-only*. Only the following discovered host parameters can be configured:

- *Templates* - link new templates or unlink manually added ones. Templates inherited from a host prototype cannot be unlinked.
- *Description* - add or edit the host description.
- *Status* - enable or disable the host.
- *Tags* - add new tags or remove manually added ones. Tags inherited from a host prototype cannot be removed. Note that tags cannot have duplicates (tags with the same name and value). If a new tag is added to the host prototype and it matches a manually added tag on a discovered host, the manually added tag will be replaced with the inherited tag during discovery.
- *Macros* - add new host macros or remove manually added ones, as well as those inherited from a host prototype; change macro values and **types**.

Note:

Discovered hosts also inherit **user macros** from the host where the discovery rule is configured. These inherited macros can be removed, and their values and types can be changed.

Discovered hosts can be deleted manually. Note, however, that they will be discovered again if discovery is enabled for them.

Hosts that are no longer discovered may be:

- automatically disabled (based on the *Disable lost resources* value of the discovery rule)
- automatically deleted (based on the *Delete lost resources* value of the discovery rule).

Note:

Zabbix does not support nested host prototypes, that is, host prototypes on hosts discovered by low-level discovery rules.

5 Notes on low-level discovery

Using LLD macros in user macro contexts

LLD macros may be used inside user macro context, for example, [in trigger prototypes](#).

Multiple LLD rules for the same item

It is possible to define several low-level discovery rules with the same discovery item.

To do that you need to define the Alias agent [parameter](#), allowing to use altered discovery item keys in different discovery rules, for example `vfs.fs.discovery[foo]`, `vfs.fs.discovery[bar]`, etc.

Data limits for return values

There is no limit for low-level discovery rule JSON data if it is received directly by Zabbix server. This is because the return values are processed without being stored in a database.

There is also no limit for custom low-level discovery rules. However, if custom low-level discovery rule data is retrieved using a user parameter, the user parameter [return value limit](#) applies.

If data has to go through Zabbix proxy, it has to store this data in the database. In such a case, [database limits](#) apply.

6 Discovery rules

Please use the sidebar to see discovery rule configuration examples for various cases.

1 Discovery of mounted filesystems

Overview

It is possible to discover mounted filesystems and their properties:

- mountpoint name
- filesystem type
- filesystem size
- inode statistics
- mount options

To do that, you may use a combination of:

- the `vfs.fs.get` agent item as the master item
- dependent low-level discovery rule and item prototypes

Configuration

Master item

Create a Zabbix agent item using the following key:

```
vfs.fs.get
```

| Item | Tags | Preprocessing |
|---|------|---------------|
| <div> <div>* Name</div> <div>vfs.fs.get item</div> </div> | | |
| <div> <div>Type</div> <div>Zabbix agent</div> </div> | | |
| <div> <div>* Key</div> <div>vfs.fs.get</div> </div> | | |
| <div> <div>* Host interface</div> <div>127.0.0.1 : 10050</div> </div> | | |
| <div> <div>Type of information</div> <div>Text</div> </div> | | |

Set the type of information to "Text" for possibly big JSON data.

The data returned by this item will contain something like the following for a mounted filesystem:

```
[
  {
    "fsname": "/",
    "fstype": "ext4",
    "bytes": {
      "total": 249405239296,
      "free": 24069537792,
      "used": 212595294208,
      "pfree": 10.170306,
      "pused": 89.829694
    },
    "inodes": {
      "total": 15532032,
      "free": 12656665,
      "used": 2875367,
      "pfree": 81.487503,
      "pused": 18.512497
    },
    "options": "rw,noatime,errors=remount-ro"
  }
]
```

Dependent LLD rule

Create a low-level discovery rule as "Dependent item" type:

Discovery rule
Preprocessing
LLD macros
Filters
Overrides

* Name
Discovery rule for vfs.fs.get

Type
Dependent item

* Key
fs.mountpoint.discovery

* Master item
Zabbix server: vfs.fs.get item

* Keep lost resources period
30d

As master item select the `vfs.fs.get` item we created.

In the "LLD macros" tab define custom macros with the corresponding JSONPath:

Discovery rule
Preprocessing
LLD macros 3
Filters
Overrides

LLD macros

| LLD macro | JSONPath |
|--------------|------------|
| {#FSNAME} | \$.fsname |
| {#FSTYPE} | \$.fstype |
| {#FSOPTIONS} | \$.options |

Add

In the "Filters" tab you may add a regular expression that filters only **read-write** filesystems:

Discovery rule
Preprocessing
LLD macros 3
Filters 1
Overrides

Filters

| Label | Macro | | Regular expression |
|-------|--------------|---------|--------------------|
| E | {#FSOPTIONS} | matches | (.*)?rw(.*)? |

Add

Dependent item prototype

Create an item prototype with "Dependent item" type in this LLD rule. As master item for this prototype select the `vfs.fs.get` item we created.

Item prototype
Tags
Preprocessing

* Name

Free disk space on {#FSNAME}, type: {#FSTYPE}

Type

Dependent item

* Key

free[{#FSNAME}]

* Master item

Zabbix server: vfs.fs.get item

Type of information

Numeric (unsigned)

Note the use of custom macros in the item prototype name and key:

- *Name*: Free disk space on {#FSNAME}, type: {#FSTYPE}
- *Key*: Free[{#FSNAME}]

As type of information, use:

- *Numeric (unsigned)* for metrics like 'free', 'total', 'used'
- *Numeric (float)* for metrics like 'pfree', 'pused' (percentage)

In the item prototype "Preprocessing" tab select JSONPath and use the following JSONPath expression as parameter:

```
$. [?(@.fsname=='{#FSNAME}')].bytes.free.first()
```

Item prototype
Tags
Preprocessing 1

Preprocessing steps

Name

Parameters

1:

JSONPath

\$. [?(@.fsname=='{#FSNAME}')].bytes.free.first()

Add

When discovery starts, one item per each mountpoint will be created. This item will return the number of free bytes for the given mountpoint.

2 Discovery of network interfaces

In a similar way as **file systems** are discovered, it is possible to also discover network interfaces.

Item key

The item key to use in the **discovery rule** is

```
net.if.discovery
```

Supported macros

You may use the {#IFNAME} macro in the discovery rule **filter** and prototypes of items, triggers and graphs.

Examples of item prototypes that you might wish to create based on "net.if.discovery":

- "net.if.in[{#IFNAME},bytes]"
- "net.if.out[{#IFNAME},bytes]"

Note that on Windows {#IFGUID} is also returned.

3 Discovery of CPUs and CPU cores

In a similar way as [file systems](#) are discovered, it is possible to also discover CPUs and CPU cores.

Item key

The item key to use in the [discovery rule](#) is

`system.cpu.discovery`

Supported macros

This discovery key returns two macros - `{#CPU.NUMBER}` and `{#CPU.STATUS}` identifying the CPU order number and status respectively. It enumerates processors from 0 to N - 1, where N is total processor count.

```
[
  {
    "{#CPU.NUMBER}": 0,
    "{#CPU.STATUS}": "online"
  },
  {
    "{#CPU.NUMBER}": 1,
    "{#CPU.STATUS}": "offline"
  },
  {
    "{#CPU.NUMBER}": 2,
    "{#CPU.STATUS}": "unknown" /* "unknown" is only on Windows */
  },
  {
    "{#CPU.NUMBER}": 3,
    "{#CPU.STATUS}": "online"
  }
]
```

Note that a clear distinction cannot be made between actual, physical processors, cores and hyperthreads. `{#CPU.STATUS}` on Linux, UNIX and BSD systems returns the status of the processor, which can be either "online" or "offline". On Windows systems, this same macro may represent a third value - "unknown" - which indicates that a processor has been detected, but no information has been collected for it yet.

CPU discovery relies on the agent's collector process to remain consistent with the data provided by the collector and save resources on obtaining the data. This has the effect of this item key not working with the test (-t) command line flag of the agent binary, which will return a NOT_SUPPORTED status and an accompanying message indicating that the collector process has not been started.

Item prototypes that can be created based on CPU discovery include, for example:

- `system.cpu.util[{#CPU.NUMBER},<type>,<mode>]`
- `system.hw.cpu[{#CPU.NUMBER},<info>]`

For detailed item key description, see [Zabbix agent item keys](#).

Notes on discovered performance counter items on NUMA systems

Some [Windows performance counters](#) might be not available for some of the logical processors at NUMA systems.

For example, items discovered with an item prototype with the key below might work only for the first NUMA node. Items for the other NUMA nodes might be in unsupported state.

```
perf_counter[\Processor({#CPU.NUMBER})\% Processor Time,60]
```

Also, a discovery rule with key "system.cpu.discovery" does not provide any low-level discovery macro values to substitute into such performance counters as:

```
perf_counter["\Processor Information(<NUMA node index>,<CPU index in NUMA node>)\% Processor Time",60]
```

While [system.cpu.util](#) items rely on different performance counters to monitor CPU utilization percentage depending on the processor group count and processor count. Also, there is a rare bug related to [processor groups on Windows](#).

4 Discovery of SNMP OIDs

Overview

In this section we will perform an SNMP **discovery** on a switch.

This discovery method of SNMP OIDs has been supported since Zabbix server/proxy 6.4.

Item key

Create an SNMP item, using the following item key in the *SNMP OID* field:

`walk[1.3.6.1.2.1.2.2.1.2,1.3.6.1.2.1.2.2.1.3]`

The screenshot shows the 'Item' configuration tab in Zabbix. The form contains the following fields:

- Name:** SNMP walk interfaces
- Type:** SNMP agent
- Key:** walk.if
- Type of information:** Text
- Host interface:** 127.0.0.1:161
- SNMP OID:** walk[1.3.6.1.2.1.2.2.1.2,1.3.6.1.2.1.2.2.1.3]

This item will perform an snmpwalk for the OIDs specified in the parameters (1.3.6.1.2.1.2.2.1.2, 1.3.6.1.2.1.2.2.1.3), returning a concatenated list of values, e.g.:

```
.1.3.6.1.2.1.2.2.1.2.1 = STRING: "lo"
.1.3.6.1.2.1.2.2.1.2.2 = STRING: "ens33"
.1.3.6.1.2.1.2.2.1.2.3 = STRING: "ens37"
.1.3.6.1.2.1.2.2.1.3.1 = INTEGER: 24
.1.3.6.1.2.1.2.2.1.3.2 = INTEGER: 6
.1.3.6.1.2.1.2.2.1.3.3 = INTEGER: 6
```

Dependent discovery rule

Go to the discovery rules of your template/host. Click on *Create discovery rule* in the upper right corner of the screen.

Fill in the required details in the **Discovery rule** tab:

- Select *Dependent item* as item type
- Select the previously created SNMP walk item as the master item
- Fill the name and key with meaningful values

The screenshot shows the 'Discovery rule' configuration tab in Zabbix. The form contains the following fields:

- Name:** Network interfaces
- Type:** Dependent item
- Key:** net.if.discovery
- Master item:** SNMP host: SNMP walk item interfaces

In the **Preprocessing** tab, select the *SNMP walk to JSON* preprocessing step.

| Discovery rule | | | | |
|----------------------|--|--|---------------------|-----------|
| Preprocessing 1 | | | | |
| LLD macros | | | | |
| Filters | | | | |
| Overrides | | | | |
| Preprocessing steps | | Parameters | | |
| 1: SNMP walk to JSON | | Field name | OID prefix | Format |
| | | {#IFDESCR} | 1.3.6.1.2.1.2.2.1.2 | Unchanged |
| | | {#IFTYPE} | 1.3.6.1.2.1.2.2.1.3 | Unchanged |
| | | Add Remove | | |

In the field name specify a valid LLD macro name. Select the corresponding OID path to discover values from.

This rule will discover entities and set:

- {#IFDESCR} macros to lo, ens33, and ens37;
- {#IFTYPE} macros set to 24, 6, and 6.

A built-in macro {#SNMPINDEX} containing the index of the discovered OIDs is applied to discovered entities. The discovered entities are grouped by {#SNMPINDEX} macro value: **1**, **2** and **3**:

```
[
  {
    "{#SNMPINDEX}": "1",
    "{#IFDESCR}": "lo",
    "{#IFTYPE}": "24"
  },
  {
    "{#SNMPINDEX}": "2",
    "{#IFDESCR}": "ens33",
    "{#IFTYPE}": "6"
  },
  {
    "{#SNMPINDEX}": "3",
    "{#IFDESCR}": "ens37",
    "{#IFTYPE}": "6"
  }
]
```

If an entity does not have the specified OID, then the corresponding macro will be omitted for this entity.

Item, trigger, graph prototypes

Item prototypes must be created as **dependent** item prototypes, using macros from the discovery rule.

Dependent items will obtain their values from the walk[] master item. Thus it will not be necessary for each discovered item to query the SNMP device independently.

Trigger and graph prototypes may also be created also by using macros from the discovery rule.

Discovered entities

When server runs, it will create real dependent items, triggers and graphs based on the values the SNMP discovery rule returns.

5 Discovery of SNMP OIDs (legacy)

Overview

In this section we will perform an SNMP **discovery** on a switch.

Item key

Unlike with file system and network interface discovery, the item does not necessarily has to have an "snmp.discovery" key - item type of SNMP agent is sufficient.

To configure the discovery rule, do the following:

- Go to: *Data collection* → *Templates*
- Click on *Discovery* in the row of an appropriate template

Templates

- ☐ [Name ▲](#) [Hosts](#) [Items](#) [Triggers](#) [Graphs](#) [Dashboards](#) [Discovery](#)
- ☐ [Interfaces SNMP](#) [Hosts](#) [Items](#) [Triggers](#) [Graphs](#) [Dashboards 1](#) [Discovery 1](#)

- Click on *Create discovery rule* in the upper right corner of the screen
- Fill in the discovery rule form with the required details as in the screenshot below

Discovery rule

Preprocessing

LLD macros

Filters 12

Overrides

* Name

Network interfaces discovery

Type

SNMP agent

* Key

net.if.discovery

* SNMP OID

discovery[{#IFALIAS},1.3.6.1.2.1.31.1.1.1.18,{#IFNAME},1.3.6.1.2.1.31.1.1.1.1,{#IF

* Update interval

1h

All mandatory input fields are marked with a red asterisk.

The OIDs to discover are defined in SNMP OID field in the following format: `discovery[{#MACRO1}, oid1, {#MACRO2}, oid2, ...,]`

where `{#MACRO1}`, `{#MACRO2}` ... are valid lld macro names and `oid1`, `oid2`... are OIDs capable of generating meaningful values for these macros. A built-in macro `{#SNMPINDEX}` containing index of the discovered OID is applied to discovered entities. The discovered entities are grouped by `{#SNMPINDEX}` macro value.

To understand what we mean, let us perform few snmpwalks on our switch:

```
$ snmpwalk -v 2c -c public 192.168.1.1 IF-MIB::ifDescr
IF-MIB::ifDescr.1 = STRING: WAN
IF-MIB::ifDescr.2 = STRING: LAN1
IF-MIB::ifDescr.3 = STRING: LAN2
```

```
$ snmpwalk -v 2c -c public 192.168.1.1 IF-MIB::ifPhysAddress
IF-MIB::ifPhysAddress.1 = STRING: 8:0:27:90:7a:75
IF-MIB::ifPhysAddress.2 = STRING: 8:0:27:90:7a:76
IF-MIB::ifPhysAddress.3 = STRING: 8:0:27:2b:af:9e
```

And set SNMP OID to: `discovery[{#IFDESCR}, ifDescr, {#IFPHYSADDRESS}, ifPhysAddress]`

Now this rule will discover entities with `{#IFDESCR}` macros set to **WAN**, **LAN1** and **LAN2**, `{#IFPHYSADDRESS}` macros set to **8:0:27:90:7a:75**, **8:0:27:90:7a:76**, and **8:0:27:2b:af:9e**, `{#SNMPINDEX}` macros set to the discovered OIDs indexes **1**, **2** and **3**:

```
[
  {
    "{#SNMPINDEX}": "1",
    "{#IFDESCR}": "WAN",
    "{#IFPHYSADDRESS}": "8:0:27:90:7a:75"
  },
  {
    "{#SNMPINDEX}": "2",
    "{#IFDESCR}": "LAN1",
    "{#IFPHYSADDRESS}": "8:0:27:90:7a:76"
  },
  {
    "{#SNMPINDEX}": "3",
```

```

    "{#IFDESCR}": "LAN2",
    "{#IFPHYSADDRESS}": "8:0:27:2b:af:9e"
  }
]

```

If an entity does not have the specified OID, then the corresponding macro will be omitted for this entity. For example if we have the following data:

```

ifDescr.1 "Interface #1"
ifDescr.2 "Interface #2"
ifDescr.4 "Interface #4"

ifAlias.1 "eth0"
ifAlias.2 "eth1"
ifAlias.3 "eth2"
ifAlias.5 "eth4"

```

Then in this case SNMP discovery `discovery[{#IFDESCR}, ifDescr, {#IFALIAS}, ifAlias]` will return the following structure:

```

[
  {
    "{#SNMPINDEX}": 1,
    "{#IFDESCR}": "Interface #1",
    "{#IFALIAS}": "eth0"
  },
  {
    "{#SNMPINDEX}": 2,
    "{#IFDESCR}": "Interface #2",
    "{#IFALIAS}": "eth1"
  },
  {
    "{#SNMPINDEX}": 3,
    "{#IFALIAS}": "eth2"
  },
  {
    "{#SNMPINDEX}": 4,
    "{#IFDESCR}": "Interface #4"
  },
  {
    "{#SNMPINDEX}": 5,
    "{#IFALIAS}": "eth4"
  }
]

```

Item prototypes

The following screenshot illustrates how we can use these macros in item prototypes:

Item prototype Tags Preprocessing 2

* Name

Interface {#IFNAME}({#IFALIAS}): Bits received

Type

SNMP agent

* Key

net.if.in[ifHCInOctets.{#SNMPINDEX}]

Type of information

Numeric (unsigned)

* SNMP OID

6 Discovery of JMX objects

Overview

It is possible to **discover** all JMX MBeans or MBean attributes or to specify a pattern for the discovery of these objects.

It is mandatory to understand the difference between an MBean and MBean attributes for discovery rule configuration. An MBean is an object which can represent a device, an application, or any resource that needs to be managed.

For example, there is an MBean which represents a web server. Its attributes are connection count, thread count, request timeout, http file cache, memory usage, etc. Expressing this thought in human comprehensive language we can define a coffee machine as an MBean which has the following attributes to be monitored: water amount per cup, average consumption of water for a certain period of time, number of coffee beans required per cup, coffee beans and water refill time, etc.

Item key

In **discovery rule** configuration, select **JMX agent** in the *Type* field.

Two item keys are supported for JMX object discovery - `jmx.discovery[]` and `jmx.get[]`:

| Item key | | |
|--|--|--|
| Return value | Parameters | Comment |
| jmx.discovery [<discovery mode>,<object name>,<unique short de-scrip-tion>] | discovery mode - one of the following: <i>attributes</i> (retrieve JMX MBean attributes, default) or <i>beans</i> (retrieve JMX MBeans) object name - object name pattern (see documentation) identifying the MBean names to be retrieved (empty by default, retrieving all registered beans) unique short description - a unique description that allows multiple JMX items with the same discovery mode and object name on the host (optional) | Examples: → <code>jmx.discovery</code> - retrieve all JMX MBean attributes → <code>jmx.discovery[beans]</code> - retrieve all JMX MBeans → <code>jmx.discovery[attributes,"*:type=GarbageCollector,name=..."]</code> - retrieve all garbage collector attributes → <code>jmx.discovery[beans,"*:type=GarbageCollector,name=..."]</code> - retrieve all garbage collectors There are some limitations to what MBean properties this item can return based on limited characters that are supported in macro name generation (supported characters can be described by the following regular expression: <code>A-Z0-9_\. \</code>). So, for example, to discover MBean properties with a hyphenated word or non-ASCII characters, you need to use <code>jmx.get []</code> . |
| jmx.get [<discovery mode>,<object name>,<unique short de-scrip-tion>] | | |

| Item key | | |
|---|--|---|
| This item returns a JSON array with MBean objects or their attributes. | discovery mode - one of the following: <i>attributes</i> (retrieve JMX MBean attributes, default) or <i>beans</i> (retrieve JMX MBeans) | When using this item, it is needed to define custom low-level discovery macros, pointing to values extracted from the returned JSON using JSONPath. |
| Compared to <code>jmx.discovery[]</code> it does not define LLD macros. | object name - object name pattern (see documentation) identifying the MBean names to be retrieved (empty by default, retrieving all registered beans) unique short description - a unique description that allows multiple JMX items with the same discovery mode and object name on the host (optional) | |

Attention:

If no parameters are passed, all MBean attributes from JMX are requested. Not specifying parameters for JMX discovery or trying to receive all attributes for a wide range like `*:type=*,name=*` may lead to potential performance problems.

Using `jmx.discovery`

This item returns a JSON object with low-level discovery macros describing MBean objects or attributes. For example, in the discovery of MBean attributes (reformatted for clarity):

```
[
  {
    "{#JMXVALUE}": "0",
    "{#JMXTYPE}": "java.lang.Long",
    "{#JMXOBJ}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "{#JMXDESC}": "java.lang:type=GarbageCollector,name=PS Scavenge,CollectionCount",
    "{#JMXATTR}": "CollectionCount"
  },
  {
    "{#JMXVALUE}": "0",
    "{#JMXTYPE}": "java.lang.Long",
    "{#JMXOBJ}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "{#JMXDESC}": "java.lang:type=GarbageCollector,name=PS Scavenge,CollectionTime",
    "{#JMXATTR}": "CollectionTime"
  },
  {
    "{#JMXVALUE}": "true",
    "{#JMXTYPE}": "java.lang.Boolean",
    "{#JMXOBJ}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "{#JMXDESC}": "java.lang:type=GarbageCollector,name=PS Scavenge,Valid",
    "{#JMXATTR}": "Valid"
  },
  {
    "{#JMXVALUE}": "PS Scavenge",
    "{#JMXTYPE}": "java.lang.String",
    "{#JMXOBJ}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "{#JMXDESC}": "java.lang:type=GarbageCollector,name=PS Scavenge,Name",
    "{#JMXATTR}": "Name"
  },
  {
    "{#JMXVALUE}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "{#JMXTYPE}": "javax.management.ObjectName",
    "{#JMXOBJ}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "{#JMXDESC}": "java.lang:type=GarbageCollector,name=PS Scavenge,ObjectName",
    "{#JMXATTR}": "ObjectName"
  }
]
```

```
]
```

In the discovery of MBeans (reformatted for clarity):

```
[
  {
    "#{JMXDOMAIN}": "java.lang",
    "#{JMXTYPE}": "GarbageCollector",
    "#{JMXOBJ}": "java.lang:type=GarbageCollector,name=PS Scavenge",
    "#{JMXNAME}": "PS Scavenge"
  }
]
```

Supported macros

The following macros are supported for use in the discovery rule **filter** and prototypes of items, triggers and graphs:

| Macro | Description |
|-------------------------------|--|
| Discovery of MBean attributes | |
| {#JMXVALUE} | Attribute value. |
| {#JMXTYPE} | Attribute type. |
| {#JMXOBJ} | Object name. |
| {#JMXDESC} | Object name including attribute name. |
| {#JMXATTR} | Attribute name. |
| Discovery of MBeans | |
| {#JMXDOMAIN} | MBean domain. (<i>Zabbix reserved name</i>) |
| {#JMXOBJ} | Object name. (<i>Zabbix reserved name</i>) |
| {#JMX<key property>} | MBean properties (like {#JMXTYPE}, {#JMXNAME}) (see Limitations below). |

Limitations

There are some limitations associated with the algorithm of creating LLD macro names from MBean property names:

- attribute names are changed to uppercase
- attribute names are ignored (no LLD macros are generated) if they consist of unsupported characters for LLD macro names. Supported characters can be described by the following regular expression: A-Z0-9_\..
- if an attribute is called "obj" or "domain" they will be ignored because of the overlap with the values of the reserved Zabbix properties {#JMXOBJ} and {#JMXDOMAIN}

Please consider this jmx.discovery (with "beans" mode) example. MBean has the following properties defined (some of which will be ignored; see below):

```
name=test
=Type
attributes []=1,2,3
Name=NameOfTheTest
domAin=some
```

As a result of JMX discovery, the following LLD macros will be generated:

- {#JMXDOMAIN} - Zabbix internal, describing the domain of MBean
- {#JMXOBJ} - Zabbix internal, describing MBean object
- {#JMXNAME} - created from "name" property

Ignored properties are:

- тип : its name contains unsupported characters (non-ASCII)
- attributes[] : its name contains unsupported characters (square brackets are not supported)
- Name : it's already defined (name=test)
- domAin : it's a Zabbix reserved name

Examples

Let's review two more practical examples of an LLD rule creation with the use of MBean. To understand the difference between an LLD rule collecting MBeans and an LLD rule collecting MBean attributes better please take a look at following table:

| MBean1 | MBean2 | MBean3 |
|------------------|------------------|------------------|
| MBean1Attribute1 | MBean2Attribute1 | MBean3Attribute1 |

| | | |
|------------------|------------------|------------------|
| MBean1Attribute2 | MBean2Attribute2 | MBean3Attribute2 |
| MBean1Attribute3 | MBean2Attribute3 | MBean3Attribute3 |

Example 1: Discovering MBeans

This rule will return 3 objects: the top row of the column: MBean1, MBean2, MBean3.

For more information about objects please refer to [supported macros](#) table, *Discovery of MBeans* section.

Discovery rule configuration collecting MBeans (without the attributes) looks like the following:

Discovery rule

Preprocessing

LLD macros

Filters

Overrides

* Name

JMX garbage collectors

Type

JMX agent

* Key

jmx.discovery[beans,"*:type=GarbageCollector,name=*"]

* Host interface

127.0.0.1 : 12345

The key used here:

```
jmx.discovery[beans,"*:type=GarbageCollector,name=*"]
```

All the garbage collectors without attributes will be discovered. As Garbage collectors have the same attribute set, we can use desired attributes in item prototypes the following way:

Item prototypes

All hosts / JMX

Enabled

JMX

Discovery list / JMX garbage collectors

Item prototypes

Trigger p

| <input type="checkbox"/> Name ▲ | Key |
|--|--------------------------------|
| <input type="checkbox"/> GC {#JMXNAME} CollectionCount | jmx[{#JMXOBJ},CollectionCount] |
| <input type="checkbox"/> GC {#JMXNAME} CollectionTime | jmx[{#JMXOBJ},CollectionTime] |
| <input type="checkbox"/> GC {#JMXNAME} Valid | jmx[{#JMXOBJ},Valid] |

The keys used here:

```
jmx[{#JMXOBJ},CollectionCount]
```

```
jmx[{#JMXOBJ},CollectionTime]
```

```
jmx[{#JMXOBJ},Valid]
```

LLD discovery rule will result in something close to this (items are discovered for two Garbage collectors):

| | | | Filter ▼ |
|--------------------------|---|----------|--|
| <input type="checkbox"/> | Name ▲ | Triggers | Key |
| <input type="checkbox"/> | ... JMX garbage collectors: GC PS MarkSweep CollectionCount | | jmx["java.lang:type=GarbageCollector,name=PS MarkSweep",CollectionCount] |
| <input type="checkbox"/> | ... JMX garbage collectors: GC PS MarkSweep CollectionTime | | jmx["java.lang:type=GarbageCollector,name=PS MarkSweep",CollectionTime] |
| <input type="checkbox"/> | ... JMX garbage collectors: GC PS MarkSweep Valid | | jmx["java.lang:type=GarbageCollector,name=PS MarkSweep",Valid] |
| <input type="checkbox"/> | ... JMX garbage collectors: GC PS Scavenge CollectionCount | | jmx["java.lang:type=GarbageCollector,name=PS Scavenge",CollectionCount] |
| <input type="checkbox"/> | ... JMX garbage collectors: GC PS Scavenge CollectionTime | | jmx["java.lang:type=GarbageCollector,name=PS Scavenge",CollectionTime] |
| <input type="checkbox"/> | ... JMX garbage collectors: GC PS Scavenge Valid | | jmx["java.lang:type=GarbageCollector,name=PS Scavenge",Valid] |

Example 2: Discovering MBean attributes

This rule will return 9 objects with the following fields: MBean1Attribute1, MBean2Attribute1, MBean3Attribute1,MBean1Attribute2,MBean2Attribute2, MBean3Attribute2, MBean1Attribute3, MBean2Attribute3, MBean3Attribute3.

For more information about objects please refer to [supported macros](#) table, *Discovery of MBean attributes* section.

Discovery rule configuration collecting MBean attributes looks like the following:

Discovery rule
Preprocessing
LLD macros
Filters
Overrides

* Name

JMX garbage collectors

Type

JMX agent

* Key

jmx.discovery[attributes,"*:type=GarbageCollector,name=*"]

* Host interface

127.0.0.1 : 12345

The key used here:

```
jmx.discovery[attributes,"*:type=GarbageCollector,name=*"]
```

All the garbage collectors with a single item attribute will be discovered.

Item prototypes

All hosts / JMX
Enabled
JMX
Discovery list / JMX garbage collectors
Item prototypes
Trigger

| <input type="checkbox"/> | Name ▲ | Key |
|--------------------------|----------------------|---------------------------|
| <input type="checkbox"/> | {#JMXOBJ} {#JMXATTR} | jmx[{#JMXOBJ},{#JMXATTR}] |

In this particular case an item will be created from prototype for every MBean attribute. The main drawback of this configuration is that trigger creation from trigger prototypes is impossible as there is only one item prototype for all attributes. So this setup can be used for data collection, but is not recommended for automatic monitoring.

Using `jmx.get`

`jmx.get []` is similar to the `jmx.discovery []` item, but it does not turn Java object properties into low-level discovery macro names and therefore can return values without [limitations](#) that are associated with LLD macro name generation such as hyphens or non-ASCII characters.

When using `jmx.get []` for discovery, low-level discovery macros can be defined separately in the custom [LLD macro](#) tab of the discovery rule configuration, using JSONPath to point to the required values.

Discovering MBeans

Discovery item: `jmx.get[beans,"com.example:type=*,*"]`

Response:

```
[
  {
    "object": "com.example:type=Hello,data-src=data-base, = ",
    "domain": "com.example",
    "properties": {
      "data-src": "data-base",
      " ": " ",
      "type": "Hello"
    }
  },
  {
    "object": "com.example:type=Atomic",
    "domain": "com.example",
    "properties": {
      "type": "Atomic"
    }
  }
]
```

Discovering MBean attributes

Discovery item: `jmx.get[attributes,"com.example:type=*,*"]`

Response:

```
[
  {
    "object": "com.example:type=*",
    "domain": "com.example",
    "properties": {
      "type": "Simple"
    }
  },
  {
    "object": "com.zabbix:type=yes,domain=zabbix.com,data-source=/dev/rand, = ,obj=true",
    "domain": "com.zabbix",
    "properties": {
      "type": "Hello",
      "domain": "com.example",
      "data-source": "/dev/rand",
      " ": " ",
      "obj": true
    }
  }
]
```

7 Discovery of IPMI sensors

Overview

It is possible to automatically discover IPMI sensors.

To do that, you may use a combination of:

- the `ipmi.get` IPMI item as the master item
- dependent low-level discovery rule and item prototypes

Configuration

Master item

Create an IPMI item using the following key:

`ipmi.get`

| Item | Tags | Preprocessing |
|---------------------|-----------------|---------------|
| * Name | IPMI get item | |
| Type | IPMI agent | |
| * Key | ipmi.get | |
| * Host interface | 127.0.0.1 : 623 | |
| IPMI sensor | | |
| Type of information | Text | |

Set the type of information to "Text" for possibly big JSON data.

Dependent LLD rule

Create a low-level discovery rule as "Dependent item" type:

| Discovery rule | Preprocessing | LLD macros | Filters | Overrides |
|----------------|--------------------------------|------------|---------|-----------|
| * Name | Discovery rule for ipmi.get | | | |
| Type | Dependent item | | | |
| * Key | ipmi.sensor.discovery | | | |
| * Master item | Zabbix server: IPMI get item X | | | |

As master item select the `ipmi.get` item we created.

In the "LLD macros" tab define a custom macro with the corresponding JSONPath:

| Discovery rule | Preprocessing | LLD macros 1 | Filters | Overrides |
|----------------|---------------|--------------|---------|-----------|
| LLD macros | | | | |
| LLD macro | | JSONPath | | |
| {#SENSOR_ID} | | \$.id | | |
| Add | | | | |

Dependent item prototype

Create an item prototype with "Dependent item" type in this LLD rule. As master item for this prototype select the `ipmi.get` item we created.

Item prototype

Tags

Preprocessing

* Name

IPMI value for sensor {#SENSOR_ID}

Type

Dependent item

* Key

ipmi_sensor[{#SENSOR_ID}]

* Master item

Zabbix server: IPMI get item

Type of information

Numeric (unsigned)

Note the use of the {#SENSOR ID} macro in the item prototype name and key:

- *Name*: IPMI value for sensor {#SENSOR_ID}
- *Key*: ipmi_sensor[{#SENSOR_ID}]

As type of information, *Numeric (unsigned)*.

In the item prototype "Preprocessing" tab select JSONPath and use the following JSONPath expression as parameter:

```
$.['?(@.id=='{#SENSOR ID}')'].value.first()
```

Item prototype

Tags

Preprocessing 1

| Preprocessing steps | Name | Parameters |
|-------------------------------------|---------------------|---|
| <div><div></div><div>1:</div></div> | <div>JSONPath</div> | <div>\$.[?(@.id=='#SENSOR_ID')].value.first()</div> |
| <div>Add</div> | | |

When discovery starts, one item per each IPMI sensor will be created. This item will return the integer value of the given sensor.

8 Discovery of systemd services

Overview

It is possible to **discover** systemd units (services, by default) with Zabbix.

Item key

The item to use in the **discovery rule** is the

systemd.unit.discovery

Attention:

This **item** key is only supported in Zabbix agent 2.

This item returns a JSON with information about systemd units, for example:

```
[{
  "{#UNIT.NAME}": "mysqld.service",
  "{#UNIT.DESCRPTION}": "MySQL Server",
  "{#UNIT.LOADSTATE}": "loaded",
  "{#UNIT.ACTIVESTATE}": "active",
  "{#UNIT.SUBSTATE}": "running",
  "{#UNIT.FOLLOWED}": "",
  "{#UNIT.PATH}": "/org/freedesktop/systemd1/unit/mysqld_2eservice",
```

```

    "{#UNIT.JOBID}": 0,
    "{#UNIT.JOBTYPE}": "",
    "{#UNIT.JOBPATH}": "/",
    "{#UNIT.UNITFILESTATE}": "enabled"
    "{#UNIT.SERVICETYPE}": "simple"
  }, {
    "{#UNIT.NAME}": "systemd-journald.socket",
    "{#UNIT.DESCRPTION}": "Journal Socket",
    "{#UNIT.LOADSTATE}": "loaded",
    "{#UNIT.ACTIVESTATE}": "active",
    "{#UNIT.SUBSTATE}": "running",
    "{#UNIT.FOLLOWED}": "",
    "{#UNIT.PATH}": "/org/freedesktop/systemd1/unit/systemd_2djournald_2esocket",
    "{#UNIT.JOBID}": 0,
    "{#UNIT.JOBTYPE}": "",
    "{#UNIT.JOBPATH}": "/",
    "{#UNIT.UNITFILESTATE}": "enabled"
  }
]]

```

Discovery of disabled systemd units

It is also possible to discover **disabled** systemd units. In this case three macros are returned in the resulting JSON:

- {#UNIT.PATH}
- {#UNIT.ACTIVESTATE}
- {#UNIT.UNITFILESTATE}.

Attention:

To have items and triggers created from prototypes for disabled systemd units, make sure to adjust (or remove) prohibiting LLD filters for {#UNIT.ACTIVESTATE} and {#UNIT.UNITFILESTATE}.

Supported macros

The following macros are supported for use in the discovery rule **filter** and prototypes of items, triggers and graphs:

| Macro | Description |
|-----------------------|--|
| {#UNIT.NAME} | Primary unit name. |
| {#UNIT.DESCRPTION} | Human readable description. |
| {#UNIT.LOADSTATE} | Load state (i.e. whether the unit file has been loaded successfully) |
| {#UNIT.ACTIVESTATE} | Active state (i.e. whether the unit is currently started or not) |
| {#UNIT.SUBSTATE} | Sub state (a more fine-grained version of the active state that is specific to the unit type, which the active state is not) |
| {#UNIT.FOLLOWED} | Unit that is being followed in its state by this unit, if there is any; otherwise an empty string. |
| {#UNIT.PATH} | Unit object path. |
| {#UNIT.JOBID} | Numeric job ID if there is a job queued for the job unit; 0 otherwise. |
| {#UNIT.JOBTYPE} | Job type. |
| {#UNIT.JOBPATH} | Job object path. |
| {#UNIT.UNITFILESTATE} | The install state of the unit file. |
| {#UNIT.SERVICETYPE} | Type of the service unit (e.g., simple, forking, oneshot, idle, etc.). This macro is returned only if the unit is a service. |

Item prototypes

Item prototypes that can be created based on systemd service discovery include, for example:

- Item name: {#UNIT.DESCRPTION} active state info; item key: systemd.unit.info["{#UNIT.NAME}"]
- Item name: {#UNIT.DESCRPTION} load state info; item key: systemd.unit.info["{#UNIT.NAME}",LoadState]

9 Discovery of Windows services

Overview

In a similar way as **file systems** are discovered, it is possible to also discover Windows services.

Item key

The item to use in the **discovery rule** is

`service.discovery`

Supported macros

The following macros are supported for use in the discovery rule **filter** and prototypes of items, triggers and graphs:

| Macro | Description |
|---------------------------|---|
| {#SERVICE.NAME} | Service name. |
| {#SERVICE.DISPLAYNAME} | Displayed service name. |
| {#SERVICE.DESCRPTION} | Service description. |
| {#SERVICE.STATE} | Numerical value of the service state. See the service.info item for details. |
| {#SERVICE.STATENAME} | Name of the service state. See the service.info item for details. |
| {#SERVICE.PATH} | Service path. |
| {#SERVICE.USER} | Service user. |
| {#SERVICE.STARTUP} | Numerical value of the service startup type. See the service.info item for details. |
| {#SERVICE.STARTUPNAME} | Name of the service startup type. See the service.info item for details. |
| {#SERVICE.STARTUPTRIGGER} | Numerical value to indicate if the service startup type has: 0 - no startup triggers 1 - has startup triggers It is useful to discover such service startup types as <i>Automatic (trigger start)</i> , <i>Automatic delayed (trigger start)</i> and <i>Manual (trigger start)</i> . |

Based on Windows service discovery you may create an **item** prototype like

```
service.info[{#SERVICE.NAME},<param>]
```

where *param* accepts the following values: *state*, *displayname*, *path*, *user*, *startup* or *description*.

For example, to acquire the display name of a service you may use a "service.info[{#SERVICE.NAME},displayname]" item. If *param* value is not specified ("service.info[{#SERVICE.NAME}]"), the default *state* parameter is used.

10 Discovery of Windows performance counter instances

Overview

It is possible to discover object instances of Windows performance counters. This is useful for multi-instance performance counters.

Item key

To configure the **discovery rule**, use the following item:

- `perf_instance.discovery[object]`

Note that the object name may be localized. For example:

```
perf_instance.discovery[Processor] # The object name is in English.  
perf_instance.discovery[Processador] # The object name is in Portuguese.
```

Alternatively, to ensure that the object name is provided in English, independent of OS localization, use the following item:

- `perf_instance_en.discovery[object]`

For example:

```
perf_instance_en.discovery[Processor]  
perf_instance_en.discovery[Memory]
```

Supported macros

The discovery process will return all instances of the specified object in the {#INSTANCE} macro:

```
[
  {"{#INSTANCE}": "0"},
  {"{#INSTANCE}": "1"},
  {"{#INSTANCE}": "_Total"}
]
```

This macro may be used in the prototypes of `perf_counter[]` and `perf_counter_en[]` items.

For example, if the item key used in the discovery rule is `perf_instance.discovery[Processor]`, you may create the following item prototype:

```
perf_counter["\\Processor({#INSTANCE})\\% Processor Time"]
```

Note:

- If the specified object is not found or does not support variable instances, the discovery item will become NOTSUPPORTED.
- If the specified object supports variable instances but currently does not have any instances, an empty JSON array will be returned.
- Duplicate instances will be skipped.

11 Discovery using WMI queries

Overview

WMI is a powerful interface in Windows that can be used for retrieving various information about Windows components, services, state and software installed.

It can be used for physical disk discovery and their performance data collection, network interface discovery, Hyper-V guest discovery, monitoring Windows services and many other things in Windows OS.

This type of low-level **discovery** is done using WQL queries whose results get automatically transformed into a JSON object suitable for low-level discovery.

Item key

The item to use in the **discovery rule** is

```
wmi.getall[<namespace>,<query>]
```

This **item** transforms the query result into a JSON array. For example:

```
select * from Win32_DiskDrive where Name like '%PHYSICALDRIVE%'
```

may return something like this:

```
[
  {
    "DeviceID" : "\\.\PHYSICALDRIVE0",
    "BytesPerSector" : 512,
    "Capabilities" : [
      3,
      4
    ],
    "CapabilityDescriptions" : [
      "Random Access",
      "Supports Writing"
    ],
    "Caption" : "VBOX HARDDISK ATA Device",
    "ConfigManagerErrorCode" : 0,
    "ConfigManagerUserConfig" : "False",
    "CreationClassName" : "Win32_DiskDrive",
    "Description" : "Disk drive",
    "FirmwareRevision" : "1.0",
    "Index" : 0,
    "InterfaceType" : "IDE"
  },
  {
    "DeviceID" : "\\.\PHYSICALDRIVE1",
    "BytesPerSector" : 512,
```

```

    "Capabilities" : [
      3,
      4
    ],
    "CapabilityDescriptions" : [
      "Random Access",
      "Supports Writing"
    ],
    "Caption" : "VBOX HARDDISK ATA Device",
    "ConfigManagerErrorCode" : 0,
    "ConfigManagerUserConfig" : "False",
    "CreationClassName" : "Win32_DiskDrive",
    "Description" : "Disk drive",
    "FirmwareRevision" : "1.0",
    "Index" : 1,
    "InterfaceType" : "IDE"
  }
]

```

Low-level discovery macros

Even though no low-level discovery macros are created in the returned JSON, these macros can be defined by the user as an additional step, using the **custom LLD macro** functionality with JSONPath pointing to the discovered values in the returned JSON.

The macros then can be used to create item, trigger, etc prototypes.

12 Discovery using ODBC SQL queries

Overview

This type of low-level **discovery** is done using SQL queries, whose results get automatically transformed into a JSON object suitable for low-level discovery.

Item key

SQL queries are performed using a "Database monitor" item type. Therefore, most of the instructions on **ODBC monitoring** page apply in order to get a working "Database monitor" discovery rule.

Two item keys may be used in "Database monitor" discovery rules:

- **db.odbc.discovery**[<unique short description>,<dsn>,<connection string>] - this item transforms the SQL query result into a JSON array, turning the column names from the query result into low-level discovery macro names paired with the discovered field values. These macros can be used in creating item, trigger, etc prototypes. See also: [Using db.odbc.discovery](#).
- **db.odbc.get**[<unique short description>,<dsn>,<connection string>] - this item transforms the SQL query result into a JSON array, keeping the original column names from the query result as a field name in JSON paired with the discovered values. Compared to `db.odbc.discovery[]`, this item does not create low-level discovery macros in the returned JSON, therefore there is no need to check if the column names can be valid macro names. The low-level discovery macros can be defined as an additional step as required, using the **custom LLD macro** functionality with JSONPath pointing to the discovered values in the returned JSON. See also: [Using db.odbc.get](#).

Using db.odbc.discovery

As a practical example to illustrate how the SQL query is transformed into JSON, let us consider low-level discovery of Zabbix proxies by performing an ODBC query on Zabbix database. This is useful for automatic creation of "zabbix[proxy,<name>,lastaccess]" **internal items** to monitor which proxies are alive.

Let us start with discovery rule configuration:

| Discovery rule | Preprocessing | LLD macros | Filters | Overrides |
|-------------------|---|------------|---------|-----------|
| * Name | Proxy discovery | | | |
| Type | Database monitor | | | |
| * Key | db.odbc.discovery[proxies,{SDSN}] | | | |
| User name | | | | |
| Password | | | | |
| * SQL query | SELECT h1.host, COUNT(h2.host) AS count FROM hosts h1 LEFT JOIN hosts h2 ON h1.hostid = h2.proxy_hostid WHERE h1.status IN (5, 6) GROUP BY h1.host; | | | |
| * Update interval | 30s | | | |

All mandatory input fields are marked with a red asterisk.

Here, the following direct query on Zabbix database is used to select all Zabbix proxies, together with the number of hosts they are monitoring. The number of hosts can be used, for instance, to filter out empty proxies:

```
mysql> SELECT h1.host, COUNT(h2.host) AS count FROM hosts h1 LEFT JOIN hosts h2 ON h1.hostid = h2.proxy_hostid
```

```
+-----+-----+
| host   | count |
+-----+-----+
| Japan 1 |    5 |
| Japan 2 |   12 |
| Latvia  |    3 |
+-----+-----+
```

```
3 rows in set (0.01 sec)
```

By the internal workings of "db.odbc.discovery[,{\$DSN}]" item, the result of this query gets automatically transformed into the following JSON:

```
[
  {
    "{#HOST}": "Japan 1",
    "{#COUNT}": "5"
  },
  {
    "{#HOST}": "Japan 2",
    "{#COUNT}": "12"
  },
  {
    "{#HOST}": "Latvia",
    "{#COUNT}": "3"
  }
]
```

It can be seen that column names become macro names and selected rows become the values of these macros.

Note:

If it is not obvious how a column name would be transformed into a macro name, it is suggested to use column aliases like "COUNT(h2.host) AS count" in the example above.

In case a column name cannot be converted into a valid macro name, the discovery rule becomes not supported, with the error message detailing the offending column number. If additional help is desired, the obtained column names are provided under DebugLevel=4 in Zabbix server log file:

```
$ grep db.odbc.discovery /tmp/zabbix_server.log
```

```
...
```

```
23876:20150114:153410.856 In db_odbc_discovery() query:'SELECT h1.host, COUNT(h2.host) FROM hosts h1 I
```

```
23876:20150114:153410.860 db_odbc_discovery() column[1]:'host'
```

```
23876:20150114:153410.860 db_odbc_discovery() column[2]:'COUNT(h2.host)'
```

```
23876:20150114:153410.860 End of db_odbc_discovery():NOTSUPPORTED
```

```
23876:20150114:153410.860 Item [Zabbix server:db.odbc.discovery[proxies,{ $DSN}]] error: Cannot convert
```

Now that we understand how a SQL query is transformed into a JSON object, we can use {#HOST} macro in item prototypes:

| Item prototype | Tags | Preprocessing |
|--------------------------|-----------------------------------|---------------|
| * Name | Last access time of proxy {#HOST} | |
| Type | Zabbix internal | |
| * Key | zabbix[proxy,{#HOST},lastaccess] | |
| Type of information | Numeric (unsigned) | |
| Units | unixtime | |
| * Update interval | 60s | |

Once discovery is performed, an item will be created for each proxy:

| <input type="checkbox"/> | Name | Triggers | Key ▲ |
|--------------------------|--|----------|--------------------------------|
| <input type="checkbox"/> | ... Proxy discovery: Last access time of proxy Japan1 | | zabbix[proxy,Japan1,lastacce |
| <input type="checkbox"/> | ... Proxy discovery: Last access time of proxy Japan2 | | zabbix[proxy,Japan2,lastacce |
| <input type="checkbox"/> | ... Proxy discovery: Last access time of proxy Latvia | | zabbix[proxy,Latvia,lastaccess |

Using db.odbc.get

Using db.odbc.get[,{\$DSN}] and the following SQL example:

```
mysql> SELECT h1.host, COUNT(h2.host) AS count FROM hosts h1 LEFT JOIN hosts h2 ON h1.hostid = h2.proxy_ho
```

```
+-----+-----+
```

```
| host    | count |
```

```
+-----+-----+
```

```
| Japan 1 |     5 |
```

```
| Japan 2 |    12 |
```

```
| Latvia  |     3 |
```

```
+-----+-----+
```

```
3 rows in set (0.01 sec)
```

this JSON will be returned:

```
[  
  {
```

```

    "host": "Japan 1",
    "count": "5"
  },
  {
    "host": "Japan 2",
    "count": "12"
  },
  {
    "host": "Latvia",
    "count": "3"
  }
]

```

As you can see, there are no low-level discovery macros there. However, custom low-level discovery macros can be created in the **LLD macros** tab of a discovery rule using JSONPath, for example:

{#HOST} → \$.host

Now this {#HOST} macro may be used in item prototypes:

| Item prototype | Tags | Preprocessing |
|---------------------|-----------------------------------|---------------|
| * Name | Last access time of proxy {#HOST} | |
| Type | Zabbix internal | |
| * Key | zabbix[proxy,{#HOST},lastaccess] | |
| Type of information | Numeric (unsigned) | |
| Units | unixtime | |
| * Update interval | 60s | |

13 Discovery using Prometheus data

Overview

Data provided in Prometheus line format can be used for low-level discovery.

See **Prometheus checks** for details how Prometheus data querying is implemented in Zabbix.

Configuration

The low-level discovery rule should be created as a **dependent item** to the HTTP master item that collects Prometheus data.

Prometheus to JSON

In the discovery rule, go to the Preprocessing tab and select the *Prometheus to JSON* preprocessing option. Data in JSON format are needed for discovery and the *Prometheus to JSON* preprocessing option will return exactly that, with the following attributes:

- metric name
- metric value
- help (if present)
- type (if present)
- labels (if present)
- raw line

For example, querying `wmi_logical_disk_free_bytes`:

| Discovery rule | Preprocessing 1 | LLD macros | Filters | Overrides | | | | | | |
|---|--------------------|--|---------|-----------|---------------------|------|------------|----|--------------------|--|
| <table border="1"> <thead> <tr> <th>Preprocessing steps</th> <th>Name</th> <th>Parameters</th> </tr> </thead> <tbody> <tr> <td>1:</td> <td>Prometheus to JSON</td> <td>wmi_logical_disk_free_bytes{volume=~".*"} Add</td> </tr> </tbody> </table> | | | | | Preprocessing steps | Name | Parameters | 1: | Prometheus to JSON | wmi_logical_disk_free_bytes{volume=~".*"} Add |
| Preprocessing steps | Name | Parameters | | | | | | | | |
| 1: | Prometheus to JSON | wmi_logical_disk_free_bytes{volume=~".*"} Add | | | | | | | | |

from these Prometheus lines:

```
# HELP wmi_logical_disk_free_bytes Free space in bytes (LogicalDisk.PercentFreeSpace)
# TYPE wmi_logical_disk_free_bytes gauge
wmi_logical_disk_free_bytes{volume="C:"} 3.5180249088e+11
wmi_logical_disk_free_bytes{volume="D:"} 2.627731456e+09
wmi_logical_disk_free_bytes{volume="HarddiskVolume4"} 4.59276288e+08
```

will return:

```
[
  {
    "name": "wmi_logical_disk_free_bytes",
    "help": "Free space in bytes (LogicalDisk.PercentFreeSpace)",
    "type": "gauge",
    "labels": {
      "volume": "C:"
    },
    "value": "3.5180249088e+11",
    "line_raw": "wmi_logical_disk_free_bytes{volume=\"C:\"} 3.5180249088e+11"
  },
  {
    "name": "wmi_logical_disk_free_bytes",
    "help": "Free space in bytes (LogicalDisk.PercentFreeSpace)",
    "type": "gauge",
    "labels": {
      "volume": "D:"
    },
    "value": "2.627731456e+09",
    "line_raw": "wmi_logical_disk_free_bytes{volume=\"D:\"} 2.627731456e+09"
  },
  {
    "name": "wmi_logical_disk_free_bytes",
    "help": "Free space in bytes (LogicalDisk.PercentFreeSpace)",
    "type": "gauge",
    "labels": {
      "volume": "HarddiskVolume4"
    },
    "value": "4.59276288e+08",
    "line_raw": "wmi_logical_disk_free_bytes{volume=\"HarddiskVolume4\"} 4.59276288e+08"
  }
]
```

Mapping LLD macros

Next you have to go to the LLD macros tab and make the following mappings:

```
{#VOLUME}=${labels['volume']}
{#METRIC}=${['name']}
{#HELP}=${['help']}
```

Item prototype

You may want to create an item prototype like this:

Item prototype
Tags
Preprocessing

* Name
Free bytes on {#VOLUME}

Type
Dependent item

* Key
wmi[{#METRIC},{#VOLUME}]
Select

Type of information
Numeric (float)

14 Discovery of block devices

In a similar way as **file systems** are discovered, it is possible to also discover block devices and their type.

Item key

The item key to use in the **discovery rule** is

`vfs.dev.discovery`

This item is supported on Linux platforms only.

You may create discovery rules using this discovery item and:

- filter: **{#DEVNAME}** matches `sd[\D]$` - to discover devices named "sd0", "sd1", "sd2", ...
- filter: **{#DEVTYPE}** matches `disk` AND **{#DEVNAME}** does not match `^loop.*` - to discover disk type devices whose name does not start with "loop"

Supported macros

This discovery key returns two macros - `{#DEVNAME}` and `{#DEVTYPE}` identifying the block device name and type respectively, e.g.:

```
[
  {
    "{#DEVNAME}": "loop1",
    "{#DEVTYPE}": "disk"
  },
  {
    "{#DEVNAME}": "dm-0",
```

```

    "{#DEVTYPE}": "disk"
  },
  {
    "{#DEVNAME}": "sda",
    "{#DEVTYPE}": "disk"
  },
  {
    "{#DEVNAME}": "sda1",
    "{#DEVTYPE}": "partition"
  }
]

```

Block device discovery allows to use `vfs.dev.read[]` and `vfs.dev.write[]` items to create item prototypes using the `{#DEVNAME}` macro, for example:

- `"vfs.dev.read[{#DEVNAME},sps]"`
- `"vfs.dev.write[{#DEVNAME},sps]"`

`{#DEVTYPE}` is intended for device filtering.

15 Discovery of host interfaces in Zabbix

Overview

It is possible to **discover** all interfaces configured in Zabbix frontend for a host.

Item key

The item to use in the **discovery rule** is the

`zabbix[host,discovery,interfaces]`

internal item.

This item returns a JSON with the description of interfaces, including:

- IP address/DNS hostname (depending on the “Connect to” host setting)
- Port number
- Interface type (Zabbix agent, SNMP, JMX, IPMI)
- If it is the default interface or not
- If the bulk request feature is enabled - for SNMP interfaces only.

For example:

```
[{"{#IF.CONN}": "192.168.3.1", "{#IF.IP}": "192.168.3.1", "{#IF.DNS}": "", "{#IF.PORT}": "10050", "{#IF.TYPE}": "AG"}]
```

With multiple interfaces their records in JSON are ordered by:

- Interface type,
- Default - the default interface is put before non-default interfaces,
- Interface ID (in ascending order).

Supported macros

The following macros are supported for use in the discovery rule **filter** and prototypes of items, triggers and graphs:

| Macro | Description |
|------------------------------|---|
| <code>{#IF.CONN}</code> | Interface IP address or DNS host name. |
| <code>{#IF.IP}</code> | Interface IP address. |
| <code>{#IF.DNS}</code> | Interface DNS host name. |
| <code>{#IF.PORT}</code> | Interface port number. |
| <code>{#IF.TYPE}</code> | Interface type ("AGENT", "SNMP", "JMX", or "IPMI"). |
| <code>{#IF.DEFAULT}</code> | Default status for the interface: 0 - not default interface 1 - default interface |
| <code>{#IF.SNMP.BULK}</code> | SNMP bulk processing status for the interface: 0 - disabled 1 - enabled This macro is returned only if interface type is "SNMP". |

7 Custom LLD rules

Overview

It is also possible to create a completely custom LLD rule, discovering any type of entities - for example, databases on a database server.

To do so, a custom item should be created that returns a JSON string, specifying found objects and optionally - some properties of them. The amount of macros per entity is not limited - while the built-in discovery rules return either one or two macros (for example, two for filesystem discovery), it is possible to return more.

Example

The required JSON string format is best illustrated with an example. Suppose we are running an old Zabbix 1.8 agent (one that does not support "vfs.fs.discovery"), but we still need to discover file systems. Here is a simple Perl script for Linux that discovers mounted file systems and outputs in JSON, which includes both file system name and type. One way to use it would be as a UserParameter with key "vfs.fs.discovery_perl":

```
####!/usr/bin/perl

$first = 1;

print "[\n";

for (`cat /proc/mounts`)
{
    ($fsname, $fstype) = m/\S+ (\S+) (\S+)/;

    print "\t,\n" if not $first;
    $first = 0;

    print "\t{\n";
    print "\t\t\"#{FSNAME}\" : \"$fsname\", \n";
    print "\t\t\"#{FSTYPE}\" : \"$fstype\" \n";
    print "\t}\n";
}

print "]\n";
```

Attention:

Allowed symbols for LLD macro names are **0-9** , **A-Z** , **_** , **.** . Lowercase letters are not supported in the names.

An example of its output (reformatted for clarity) is shown below. JSON for custom discovery checks has to follow the same format.

```
[
    { "#{FSNAME}": "/",           "#{FSTYPE}": "rootfs" },
    { "#{FSNAME}": "/sys",        "#{FSTYPE}": "sysfs" },
    { "#{FSNAME}": "/proc",       "#{FSTYPE}": "proc" },
    { "#{FSNAME}": "/dev",        "#{FSTYPE}": "devtmpfs" },
    { "#{FSNAME}": "/dev/pts",    "#{FSTYPE}": "devpts" },
    { "#{FSNAME}": "/lib/init/rw", "#{FSTYPE}": "tmpfs" },
    { "#{FSNAME}": "/dev/shm",    "#{FSTYPE}": "tmpfs" },
    { "#{FSNAME}": "/home",       "#{FSTYPE}": "ext3" },
    { "#{FSNAME}": "/tmp",        "#{FSTYPE}": "ext3" },
    { "#{FSNAME}": "/usr",        "#{FSTYPE}": "ext3" },
    { "#{FSNAME}": "/var",        "#{FSTYPE}": "ext3" },
    { "#{FSNAME}": "/sys/fs/fuse/connections", "#{FSTYPE}": "fusectl" }
]
```

In the previous example it is required that the keys match the LLD macro names used in prototypes, the alternative is to extract LLD macro values using JSONPath {#FSNAME} → \$.fsname and {#FSTYPE} → \$.fstype, thus making such script possible:

```
####!/usr/bin/perl

$first = 1;
```

```

print "[\n";

for (`cat /proc/mounts`)
{
    ($fsname, $fstype) = m/\S+ (\S+) (\S+)/;

    print "\t,\n" if not $first;
    $first = 0;

    print "\t{\n";
    print "\t\t\"fsname\": \"$fsname\", \n";
    print "\t\t\"fstype\": \"$fstype\" \n";
    print "\t}\n";
}

print "]\n";

```

An example of its output (reformatted for clarity) is shown below. JSON for custom discovery checks has to follow the same format.

```

[
  { "fsname": "/", "fstype": "rootfs" },
  { "fsname": "/sys", "fstype": "sysfs" },
  { "fsname": "/proc", "fstype": "proc" },
  { "fsname": "/dev", "fstype": "devtmpfs" },
  { "fsname": "/dev/pts", "fstype": "devpts" },
  { "fsname": "/lib/init/rw", "fstype": "tmpfs" },
  { "fsname": "/dev/shm", "fstype": "tmpfs" },
  { "fsname": "/home", "fstype": "ext3" },
  { "fsname": "/tmp", "fstype": "ext3" },
  { "fsname": "/usr", "fstype": "ext3" },
  { "fsname": "/var", "fstype": "ext3" },
  { "fsname": "/sys/fs/fuse/connections", "fstype": "fusectl" }
]

```

Then, in the discovery rule's "Filter" field, we could specify "{#FSTYPE}" as a macro and "rootfs|ext3" as a regular expression.

Note:

You don't have to use macro names FSNAME/FSTYPE with custom LLD rules, you are free to use whatever names you like. In case JSONPath is used then LLD row will be an array element that can be an object, but it can be also another array or a value.

Note that, if using a user parameter, the return value is limited to 16MB. For more details, see [data limits for LLD return values](#).

16 Distributed monitoring

Overview Zabbix provides an effective and reliable way of monitoring a distributed IT infrastructure using Zabbix [proxies](#).

Proxies can be used to collect data locally on behalf of a centralized Zabbix server and then report the data to the server.

Proxy features

When making a choice of using/not using a proxy, several considerations must be taken into account.

| | Proxy |
|------------------------------------|-------------------------|
| <i>Lightweight</i> | Yes |
| <i>GUI</i> | No |
| <i>Works independently</i> | Yes |
| <i>Easy maintenance</i> | Yes |
| <i>Automatic DB creation</i> | Yes ¹ |
| <i>Local administration</i> | No |
| <i>Ready for embedded hardware</i> | Yes |

| | Proxy |
|---------------------------|-------|
| One way TCP connections | Yes |
| Centralized configuration | Yes |
| Generates notifications | No |

¹ Automatic DB creation feature works only with SQLite. Other supported databases require **manual setup**.

Attention:

The Zabbix proxy is not aware of maintenance periods; see **Calculation of queues during maintenance** for details.

1 Proxies

Overview A Zabbix proxy can collect performance and availability data on behalf of the Zabbix server. This way, a proxy can take on itself some of the load of collecting data and offload the Zabbix server.

Also, using a proxy is the easiest way of implementing centralized and distributed monitoring, when all agents and proxies report to one Zabbix server and all data is collected centrally.

A Zabbix proxy can be used to:

- Monitor remote locations
- Monitor locations having unreliable communications
- Offload the Zabbix server when monitoring thousands of devices
- Simplify the maintenance of distributed monitoring

The proxy requires only one TCP connection to the Zabbix server. This way it is easier to get around a firewall as you only need to configure one firewall rule.

Attention:

Zabbix proxy must use a separate database. Pointing it to the Zabbix server database will break the configuration.

All data collected by the proxy is stored locally before transmitting it over to the server. This way no data is lost due to any temporary communication problems with the server. The *ProxyLocalBuffer* and *ProxyOfflineBuffer* parameters in the **proxy configuration file** control for how long the data are kept locally.

Attention:

It may happen that a proxy, which receives the latest configuration changes directly from Zabbix server database, has a more up-to-date configuration than Zabbix server whose configuration may not be updated as fast due to the value of **CacheUpdateFrequency**. As a result, proxy may start gathering data and send them to Zabbix server that ignores these data.

Zabbix proxy is a data collector. It does not calculate triggers, process events or send alerts. For an overview of what proxy functionality is, review the following table:

| Function | Supported by proxy |
|-------------------------------------|-------------------------|
| Items | |
| <i>Zabbix agent checks</i> | Yes |
| <i>Zabbix agent checks (active)</i> | Yes ¹ |
| <i>Simple checks</i> | Yes |
| <i>Trapper items</i> | Yes |
| <i>SNMP checks</i> | Yes |
| <i>SNMP traps</i> | Yes |
| <i>IPMI checks</i> | Yes |
| <i>JMX checks</i> | Yes |
| <i>Log file monitoring</i> | Yes |
| <i>Internal checks</i> | Yes |
| <i>SSH checks</i> | Yes |
| <i>Telnet checks</i> | Yes |
| <i>External checks</i> | Yes |
| <i>Dependent items</i> | Yes |
| <i>Script items</i> | Yes |
| <i>Browser items</i> | Yes |
| Built-in web monitoring | Yes |
| Item value preprocessing | Yes |
| Network discovery | Yes |
| Active agent autoregistration | Yes |
| Low-level discovery | Yes ² |
| Remote commands | Yes |
| Calculating triggers | No |
| Processing events | No |
| Event correlation | No |
| Sending alerts | No |

Note:

[1] To make sure that an agent asks the proxy (and not the server) for active checks, the proxy must be listed in the **ServerActive** parameter in the agent configuration file.
[2] For LLD, Zabbix proxy only collects and preprocesses the data and then sends it to Zabbix server for further processing.

Protection from overloading

If Zabbix server was down for some time, and proxies have collected a lot of data, and then the server starts, it may get overloaded (history cache usage stays at 95-100% for some time). This overload could result in a performance hit, where checks are processed slower than they should. Protection from this scenario was implemented to avoid problems that arise due to overloading history cache.

When Zabbix server history cache is full the history cache write access is being throttled, stalling server data gathering processes. The most common history cache overload case is after server downtime when proxies are uploading gathered data. To avoid this proxy throttling was added (currently it cannot be disabled).

Zabbix server will stop accepting data from proxies when history cache usage reaches 80%. Instead those proxies will be put on a throttling list. This will continue until the cache usage falls down to 60%. Now server will start accepting data from proxies one by one, defined by the throttling list. This means the first proxy that attempted to upload data during the throttling period will be served first and until it's done the server will not accept data from other proxies.

This throttling mode will continue until either cache usage hits 80% again or falls down to 20% or the throttling list is empty. In the first case the server will stop accepting proxy data again. In the other two cases the server will start working normally, accepting data from all proxies.

The above information can be illustrated in the following table:

| History write cache usage | Zabbix server mode | Zabbix server action |
|---------------------------|--------------------|---|
| Reaches 80% | Wait | Stops accepting proxy data, but maintains a <i>throttling list</i> (prioritized list of proxies to be contacted later). |
| Drops to 60% | Throttled | Starts processing the throttling list, but still not accepting proxy data. |
| Drops to 20% | Normal | Drops the throttling list and starts accepting proxy data normally. |

You may use the `zabbix[ocache,history,pused]` internal item to correlate this behavior of Zabbix server with a metric.

Configuration Once you have **installed** and **configured** a proxy, it is time to configure it in the Zabbix frontend.

Adding proxies

To configure a proxy in Zabbix frontend:

- Go to: *Administration* → *Proxies*
- Click on *Create proxy*

| Parameter | Description |
|---------------------------|---|
| Proxy name | Enter the proxy name. It must be the same name as in the <i>Hostname</i> parameter in the proxy configuration file. |
| Proxy group | Select the proxy group for proxy load balancing/high availability . Only one group can be selected. |
| Address for active agents | Enter address the monitored active agents or senders must connect to. Supported only for Zabbix 7.0 agents or later. |
| Address | This address is used to connect to both active and passive proxies. This field is only available if a proxy group is selected in the <i>Proxy group</i> field. |
| Port | TCP port number (10051 by default) to connect to. User macros are supported. |
| Proxy mode | Select the proxy mode. Active - the proxy will connect to the Zabbix server and request configuration data Passive - Zabbix server connects to the proxy <i>Note</i> that without encrypted communications (sensitive) proxy configuration data may become available to parties having access to the Zabbix server trapper port when using an active proxy. This is possible because anyone may pretend to be an active proxy and request configuration data if authentication does not take place or proxy addresses are not limited in the <i>Proxy address</i> field. |
| Proxy address | If specified then active proxy requests are only accepted from this list of comma-delimited IP addresses, optionally in CIDR notation, or DNS names of active Zabbix proxy. This field is only available if an active proxy is selected in the <i>Proxy mode</i> field. Macros are not supported. |
| Interface | Enter interface details for a passive proxy. |
| Address | This field is only available if a passive proxy is selected in the <i>Proxy mode</i> field. |
| Port | IP address/DNS name of the passive proxy. TCP port number of the passive proxy (10051 by default). User macros are supported. |

689

| Parameter | Description |
|--------------------|------------------------------|
| <i>Description</i> | Enter the proxy description. |

The **Encryption** tab allows you to require encrypted connections with the proxy.

| Parameter | Description |
|-------------------------------|--|
| <i>Connections to proxy</i> | How the server connects to the passive proxy: no encryption (default), using PSK (pre-shared key) or certificate. |
| <i>Connections from proxy</i> | Select what type of connections are allowed from the active proxy. Several connection types can be selected at the same time (useful for testing and switching to other connection type). Default is "No encryption". |
| <i>Issuer</i> | Allowed issuer of certificate. Certificate is first validated with CA (certificate authority). If it is valid, signed by the CA, then the <i>Issuer</i> field can be used to further restrict allowed CA. This field is optional, intended to use if your Zabbix installation uses certificates from multiple CAs. |
| <i>Subject</i> | Allowed subject of certificate. Certificate is first validated with CA. If it is valid, signed by the CA, then the <i>Subject</i> field can be used to allow only one value of <i>Subject</i> string. If this field is empty then any valid certificate signed by the configured CA is accepted. |
| <i>PSK identity</i> | Pre-shared key identity string. Do not put sensitive information in the PSK identity, it is transmitted unencrypted over the network to inform a receiver which PSK to use. |
| <i>PSK</i> | Pre-shared key (hex-string). Maximum length: 512 hex-digits (256-byte PSK) if Zabbix uses GnuTLS or OpenSSL library, 64 hex-digits (32-byte PSK) if Zabbix uses mbed TLS (PolarSSL) library. Example: 1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952 |

The **Timeouts** tab allows you to override **global** timeouts for item types that support it.

Time suffixes, e.g. 30s, 1m, and user macros are supported.</p> <p>Clicking the <i>Global timeouts</i> link allows you to configure global timeouts. Note that the <i>Global timeouts</i> link is visible only to users of <i>Super admin</i> type with permissions to the <i>Administration</i> → General frontend section.</p> <p>Supported item types:</p> <ul style="list-style-type: none"> - Zabbix agent (both passive and active checks) - Simple check (except icmping*, vmware.* items) - SNMP agent (only for SNMP walk [OID] and get [OID] items) - External check - Database monitor - HTTP agent - SSH agent - TELNET agent - Script - Browser <p>Note that the timeouts set under Override will prevail over the global ones but will be overridden by individual item timeouts if those are set under item configuration.</p> |

Note:

If proxy major version does not match server major version,  icon will be displayed next to *Timeouts for item types*, with the hover message "Timeouts disabled because the proxy and server versions do not match". In such cases, the proxy will use the **Timeout** parameter from the proxy configuration file.

The editing form of an existing proxy has the following additional buttons:

- *Refresh configuration* - refresh configuration of the proxy
- *Clone* - create a new proxy based on the properties of the existing proxy
- *Delete* - delete the proxy

Host configuration

You can specify that an individual host should be monitored by a proxy or proxy group in the **host configuration** form, using the *Monitored by* field.

Monitored by

Server

Proxy

Proxy group

Riga ×

Select

Host **mass update** is another way of specifying that hosts should be monitored by a proxy or proxy group.

1 Synchronization of monitoring configuration

Overview

This page provides details on the monitoring configuration update for the proxy, i.e. how changes made to the monitoring configuration on the server are synchronized to the proxy.

Incremental update

The proxy configuration update is incremental. During a configuration sync only the modified entities are updated (thus, if no entities have been modified, nothing will be sent). This approach allows to save resources and set a smaller interval (almost instant) for the proxy configuration update.

Proxy configuration changes are tracked using revision numbers. Only entities with revisions larger than the proxy configuration revision are included in configuration data sent to the proxy.

The entities for a configuration sync are as follows:

| Entity | Details |
|----------------------------------|---|
| <i>autoregistration tls data</i> | All autoregistration TLS data. |
| <i>expressions</i> | All expressions (regular expressions, expression tables). |
| <i>global configuration</i> | Global configuration defined in the 'config' table |
| <i>host</i> | All properties, interfaces, inventory, items, item preprocessing, item parameters, web scenarios of a host. |
| <i>host macros</i> | All macros defined on a host and all template IDs linked to it. |
| <i>proxy discovery rule</i> | Discovery rules and checks assigned to a proxy. |

That means:

- If an item is changed on a **host**, all configuration of that host will be synced.
- If a **regular expression** is changed, all regular expressions will be synced.

An exception are the host macros which are sent also if anything on the host has been changed.

The `-R config_cache_reload` command on the proxy will also initiate an incremental update.

Note that a full configuration sync will take place on a proxy start/restart, HA failover, if the session token has changed, or if the configuration update failed on the proxy, for example, if the connection was broken while receiving configuration data.

Configuration parameters

The **ProxyConfigFrequency** parameter determines how often the proxy configuration is synced with the server (10 seconds by default).

Note that ProxyConfigFrequency is:

- server parameter for passive proxies
- proxy parameter for active proxies

On active proxies ProxyConfigFrequency is a new parameter since Zabbix 6.4 and must be used instead of the now-deprecated ConfigFrequency.

Attention:

If both ProxyConfigFrequency and ConfigFrequency are used, the proxy will log an error and terminate.

Calculation of queues during maintenance

Attention:

The Zabbix proxy is not aware of maintenance periods; see [Calculation of queues during maintenance](#) for details.

2 Proxy load balancing and high availability

Overview

Proxy load balancing allows monitoring hosts by a proxy group with automated distribution of hosts between proxies and high proxy availability.

If one proxy from the proxy group goes offline, its hosts will be immediately distributed among other proxies having the least assigned hosts in the group. Or, if a proxy has too many/too few hosts compared to the group average, group re-balancing by distributing hosts evenly will be triggered.

Host redistribution happens only in online proxy groups. A proxy group is "online" if the configured minimum number of its proxies are online (not offline or unknown).

Note:

The minimum number of online proxies should be less than the proxy total in the group. In a group of 10 proxies, setting the minimum online proxy count to 10 creates a situation where the whole group will go offline if only one proxy fails. It is better to have 6 online proxies required. This will support 4 unhealthy proxies.

The proxy state is:

- **online** - if there was communication with it for the **failover delay** period (passive proxy responded to server requests and active proxy sent a request to server);
- **offline** - if there was no communication with it for the failover delay period;
- **unknown** - after proxy creation or server start.

You can monitor the proxy group state with the `zabbix[proxy group,<name>,state]` and `zabbix[proxy group,discovery]` internal items.

Proxy load balancing and high availability is managed by the **proxy group manager** process. The proxy group manager always knows which other proxies are healthy or unhealthy.

Version compatibility

- Only Zabbix agents 7.0 and later are supported for working with proxy groups in active mode;
- Zabbix pre-7.0 version proxies and the hosts monitored by these proxies are excluded from re-balancing operations until they are upgraded.

Host reassignment

Zabbix server checks the balance between host assignments to the proxies. The group is considered "out of balance" if there is:

- **host excess** - a proxy has many more hosts than the group average;
- **host deficit** - a proxy has far fewer hosts than the group average.

The group is considered "out of balance" if the number of hosts assigned to the proxy is above/below the group average by at least **10** and a factor of **2**. In this case the group is marked by the server for host reassignment after the grace period (10 x failover delay), if the balance is not restored.

The following table illustrates with example numbers when host reassignment is (or is not) triggered:

| Number of hosts on proxy | Group average | Host reassignment |
|--------------------------|---------------|-------------------|
| 100 | 50 | Yes |
| 60 | 50 | No |
| 40 | 50 | No |
| 25 | 50 | Yes |
| 15 | 5 | Yes |
| 10 | 5 | No |

The proxy group manager will re-distribute hosts in proxy groups in the following way:

- calculate the average number of hosts per proxy;
- for proxies with host excess - move excess hosts to unassigned hosts;
- for proxies with host deficit - calculate the number of hosts needed to balance proxies;
- remove the missing number of hosts from proxies with most hosts;
- distribute unassigned hosts between proxies with least hosts.

Using Zabbix sender with proxy groups

Use the `-g` option when sending values from different hosts in the input file to a proxy in proxy group to avoid some of the values being sent to the wrong proxy.

Configuring proxy load balancing

To configure proxy load balancing for monitoring hosts:

1. Create a proxy group (see "Configuring a proxy group" below).

For passive checks, all proxies of the group must be listed in the `Server` parameter of agents.

Adding all proxies of the group to the `ServerActive` agent parameter (separated by a **semicolon**) of monitored hosts is beneficial, but not mandatory. An active agent can have a single proxy in the `ServerActive` field and proxy load balancing will work. When the agent service starts, the agent will receive a full list of all IP addresses of all Zabbix proxies, load and keep into memory. Active checks (and Zabbix sender data requests) will be redirected to the correct online proxy for the host, based on the current proxy-host assignment.

Warning:

Having only a single proxy in `ServerActive` field may lead to lost monitoring data if the agent is started/rebooted while that particular proxy is offline.

2. Make sure the proxy group is online.

3. Configure that hosts are monitored by proxy group (not individual proxies). You may use host **mass update** to move hosts from proxy to the proxy group.

Attention:

Hosts monitored by a single proxy (even if it belongs to a proxy group) are not involved in load balancing/high availability. Additionally, having fewer than 10 hosts assigned to a proxy group may lead to uneven host distribution among proxies in the group.

4. Wait a few seconds for configuration update and for host distribution among proxies in the proxy group. Observe the change by refreshing the host list in *Monitoring -> Hosts*.

When a host is created based on auto registration/network discovery data from a proxy belonging to proxy group - then this host is set to be monitored by this proxy group.

Limitations

- SNMP traps are not supported by proxies in proxy group.
- Checks depending on external configuration must have the same configuration on all proxies in proxy group. That includes:
 - external checks - scripts;
 - database checks - ODBC configuration.
- When using the "Database monitoring" item, the DB object/server must have extended permissions.
- When monitored in proxy group the VMware hosts will be randomly spread between proxies in the group and will cause each proxy to cache all VMware data causing additional load to vCenter.

Possible firewall issues

Agents must always be allowed to reach all proxies at the firewall level. Consider the following scenarios:

- In Zabbix agent active checks, on agent startup, the first proxy responds and redirects to another proxy. The other proxy is not reachable because of a firewall problem and the communication stops in a state of waiting for the other proxy to respond. The root cause of this situation is that the first proxy knew that the other proxy was healthy for sure. This is not a problem if the first proxy fails; then it will try different addresses configured in the "ServerActive" parameter.
- The HA setup has been stable for multiple months. Host rebalancing never happens; it is not needed. The agent does not need to validate the "backup" channel to any other proxies. In a failover scenario, it might fail because a firewall was modified half a year ago.

Configuring a proxy group

To configure a proxy group in Zabbix frontend:

- Go to: *Administration -> Proxy groups*
- Click on *Create proxy group*

| Parameter | Description |
|----------------------------------|--|
| <i>Minimum number of proxies</i> | Enter the minimum number of online proxies required for the group to be online (1 by default; allowed range 1-1000). User macros are supported. |
| <i>Description</i> | Enter the proxy group description. |
| <i>Proxies</i> | List of proxies in the group. Up to five proxies can be displayed (as links or in plain text, depending on permissions to the proxy). This list is displayed when editing an existing proxy group, if there is at least one proxy in the group. |

17 Encryption

Overview Zabbix supports encrypted communications between Zabbix components using Transport Layer Security (TLS) protocol v.1.2 and 1.3 (depending on the crypto library). Certificate-based and pre-shared key-based encryption is supported.

Encryption can be configured for connections:

- Between Zabbix server, Zabbix proxy, Zabbix agent, Zabbix web service, zabbix_sender and zabbix_get utilities
- To Zabbix database **from Zabbix frontend and server/proxy**

Encryption is optional and configurable for individual components:

- Some proxies and agents can be configured to use certificate-based encryption with the server, while others can use pre-shared key-based encryption, and yet others continue with unencrypted communications (as before)
- Server (proxy) can use different encryption configurations for different hosts

Zabbix daemon programs use one listening port for encrypted and unencrypted incoming connections. Adding an encryption does not require opening new ports on firewalls.

Limitations

- Private keys are stored in plain text in files readable by Zabbix components during startup
- Pre-shared keys are entered in Zabbix frontend and stored in Zabbix database in plain text
- Built-in encryption does not protect communications:
 - Between the web server running Zabbix frontend and user web browser
 - Between Zabbix frontend and Zabbix server
- Currently each encrypted connection opens with a full TLS handshake, no session caching and tickets are implemented
- Adding encryption increases the time for item checks and actions, depending on network latency:
 - For example, if packet delay is 100ms then opening a TCP connection and sending unencrypted request takes around 200ms. With encryption about 1000 ms are added for establishing the TLS connection;
 - Timeouts may need to be increased, otherwise some items and actions running remote scripts on agents may work with unencrypted connections, but fail with timeout with encrypted.
- Encryption is not supported by **network discovery**. Zabbix agent checks performed by network discovery will be unencrypted and if Zabbix agent is configured to reject unencrypted connections such checks will not succeed.

Compiling Zabbix with encryption support To support encryption Zabbix must be compiled and linked with one of the supported crypto libraries:

- GnuTLS - from version 3.1.18
- OpenSSL - versions 1.0.1, 1.0.2, 1.1.0, 1.1.1, 3.0.x
- LibreSSL - tested with versions 2.7.4, 2.8.2:
 - LibreSSL 2.6.x is not supported
 - LibreSSL is supported as a compatible replacement of OpenSSL; the new `tls_*`() LibreSSL-specific API functions are not used. Zabbix components compiled with LibreSSL will not be able to use PSK, only certificates can be used.

Note:

You can find out more about setting up SSL for Zabbix frontend by referring to these **best practices**.

The library is selected by specifying the respective option to "configure" script:

- `--with-gnutls [=DIR]`
- `--with-openssl [=DIR]` (also used for LibreSSL)

For example, to configure the sources for server and agent with *OpenSSL* you may use something like:

```
./configure --enable-server --enable-agent --with-mysql --enable-ipv6 --with-net-snmp --with-libcurl --with-
```

Different Zabbix components may be compiled with different crypto libraries (e.g. a server with *OpenSSL*, an agent with *GnuTLS*).

Attention:
If you plan to use pre-shared keys (PSK), consider using *GnuTLS* or *OpenSSL 1.1.0* (or newer) libraries in Zabbix components using PSKs. *GnuTLS* and *OpenSSL 1.1.0* libraries support PSK ciphersuites with [Perfect Forward Secrecy](#). Older versions of the *OpenSSL* library (1.0.1, 1.0.2c) also support PSKs, but available PSK ciphersuites do not provide Perfect Forward Secrecy.

Connection encryption management Connections in Zabbix can use:

- no encryption (default)
- **RSA certificate-based encryption**
- **PSK-based encryption**

There are two important parameters used to specify encryption between Zabbix components:

- **TLSConnect** - specifies what encryption to use for outgoing connections (unencrypted, PSK or certificate)
- **TLSAccept** - specifies what types of connections are allowed for incoming connections (unencrypted, PSK or certificate). One or more values can be specified.

TLSConnect is used in the configuration files for Zabbix proxy (in active mode, specifies only connections to server) and Zabbix agent (for active checks). In Zabbix frontend the **TLSConnect** equivalent is the *Connections to host* field in *Data collection* → *Hosts* → *<some host>* → *Encryption* tab and the *Connections to proxy* field in *Administration* → *Proxies* → *<some proxy>* → *Encryption* tab. If the configured encryption type for connection fails, no other encryption types will be tried.

TLSAccept is used in the configuration files for Zabbix proxy (in passive mode, specifies only connections from server) and Zabbix agent (for passive checks). In Zabbix frontend the **TLSAccept** equivalent is the *Connections from host* field in *Data collection* → *Hosts* → *<some host>* → *Encryption* tab and the *Connections from proxy* field in *Administration* → *Proxies* → *<some proxy>* → *Encryption* tab.

Normally you configure only one type of encryption for incoming connections. But you may want to switch the encryption type, e.g. from unencrypted to certificate-based with minimum downtime and rollback possibility. To achieve this:

- Set **TLSAccept=unencrypted,cert** in the agent configuration file and restart Zabbix agent
- Test connection with `zabbix_get` to the agent using certificate. If it works, you can reconfigure encryption for that agent in Zabbix frontend in the *Data collection* → *Hosts* → *<some host>* → *Encryption* tab by setting *Connections to host* to "Certificate".
- When server configuration cache gets updated (and proxy configuration is updated if the host is monitored by proxy) then connections to that agent will be encrypted
- If everything works as expected you can set **TLSAccept=cert** in the agent configuration file and restart Zabbix agent. Now the agent will be accepting only encrypted certificate-based connections. Unencrypted and PSK-based connections will be rejected.

In a similar way it works on server and proxy. If in Zabbix frontend in host configuration *Connections from host* is set to "Certificate" then only certificate-based encrypted connections will be accepted from the agent (active checks) and `zabbix_sender` (trapper items).

Most likely you will configure incoming and outgoing connections to use the same encryption type or no encryption at all. But technically it is possible to configure it asymmetrically, e.g. certificate-based encryption for incoming and PSK-based for outgoing connections.

Encryption configuration for each host is displayed in the Zabbix frontend, in *Data collection* → *Hosts* in the *Agent encryption* column. For example:

| Example | Connections to host | Allowed connections from host | Rejected connections from host |
|---|------------------------------|-------------------------------------|--|
|  | Unencrypted | Unencrypted | Encrypted, certificate and PSK-based encrypted |
|  | Encrypted, certificate-based | Encrypted, certificate-based | Unencrypted and PSK-based encrypted |
|  | Encrypted, PSK-based | Encrypted, PSK-based | Unencrypted and certificate-based encrypted |
|  | Encrypted, PSK-based | Unencrypted and PSK-based encrypted | Certificate-based encrypted |

| Example | Connections to host | Allowed connections from host | Rejected connections from host |
|---|---------------------------------|--|--------------------------------|
|     | Encrypted, certificate-based | Unencrypted, PSK or certificate-based encrypted | - |

Attention:

Connections are unencrypted by default. Encryption must be configured for each host and proxy individually.

zabbix_get and zabbix_sender with encryption See [zabbix_get](#) and [zabbix_sender](#) manpages for using them with encryption.

Ciphersuites Ciphersuites by default are configured internally during Zabbix startup.

Also user-configured ciphersuites are supported for GnuTLS and OpenSSL. Users may **configure** ciphersuites according to their security policies. Using this feature is optional (built-in default ciphersuites still work).

For crypto libraries compiled with default settings Zabbix built-in rules typically result in the following ciphersuites (in order from higher to lower priority):

| Library | Certificate ciphersuites | PSK ciphersuites |
|-----------------------|---|--|
| <i>GnuTLS 3.1.18</i> | TLS_ECDHE_RSA_AES_128_GCM_SHA256 TLS_ECDHE_RSA_AES_128_CBC_SHA256 TLS_ECDHE_RSA_AES_128_CBC_SHA1 TLS_RSA_AES_128_GCM_SHA256 TLS_RSA_AES_128_CBC_SHA256 TLS_RSA_AES_128_CBC_SHA1 | TLS_ECDHE_PSK_AES_128_CBC_SHA256 TLS_ECDHE_PSK_AES_128_CBC_SHA1 TLS_PSK_AES_128_GCM_SHA256 TLS_PSK_AES_128_CBC_SHA256 TLS_PSK_AES_128_CBC_SHA1 |
| <i>OpenSSL 1.0.2c</i> | ECDHE-RSA-AES128-GCM-SHA256 ECDHE-RSA-AES128-SHA256 ECDHE-RSA-AES128-SHA AES128-GCM-SHA256 AES128-SHA256 AES128-SHA | PSK-AES128-CBC-SHA |
| <i>OpenSSL 1.1.0</i> | ECDHE-RSA-AES128-GCM-SHA256 ECDHE-RSA-AES128-SHA256 ECDHE-RSA-AES128-SHA AES128-GCM-SHA256 AES128-CCM8 AES128-CCM AES128-SHA256 AES128-SHA | ECDHE-PSK-AES128-CBC-SHA256 ECDHE-PSK-AES128-CBC-SHA PSK-AES128-GCM-SHA256 PSK-AES128-CCM8 PSK-AES128-CCM PSK-AES128-CBC-SHA256 PSK-AES128-CBC-SHA |
| <i>OpenSSL 1.1.1d</i> | TLS_AES_256_GCM_SHA384 TLS_CHACHA20_POLY1305_SHA256 TLS_AES_128_GCM_SHA256 ECDHE-RSA-AES128-GCM-SHA256 ECDHE-RSA-AES128-SHA256 ECDHE-RSA-AES128-SHA AES128-GCM-SHA256 AES128-CCM8 AES128-CCM AES128-SHA256 AES128-SHA | TLS_CHACHA20_POLY1305_SHA256 TLS_AES_128_GCM_SHA256 ECDHE-PSK-AES128-CBC-SHA256 ECDHE-PSK-AES128-CBC-SHA PSK-AES128-GCM-SHA256 PSK-AES128-CCM8 PSK-AES128-CCM PSK-AES128-CBC-SHA256 PSK-AES128-CBC-SHA |

User-configured ciphersuites The built-in ciphersuite selection criteria can be overridden with user-configured ciphersuites.

Attention:

User-configured ciphersuites is a feature intended for advanced users who understand TLS ciphersuites, their security and consequences of mistakes, and who are comfortable with TLS troubleshooting.

The built-in ciphersuite selection criteria can be overridden using the following parameters:

| Override scope | Parameter | Value | Description |
|---|-----------------|---|--|
| Ciphersuite selection for certificates | TLSCipherCert13 | Valid OpenSSL 1.1.1 cipher strings for TLS 1.3 protocol (their values are passed to the OpenSSL function <code>SSL_CTX_set_ciphersuites()</code>). | Certificate-based ciphersuite selection criteria for TLS 1.3 Only OpenSSL 1.1.1 or newer. |
| | TLSCipherCert | Valid OpenSSL cipher strings for TLS 1.2 or valid GnuTLS priority strings . Their values are passed to the <code>SSL_CTX_set_cipher_list()</code> or <code>gnutls_priority_init()</code> functions, respectively. | Certificate-based ciphersuite selection criteria for TLS 1.2/1.3 (GnuTLS), TLS 1.2 (OpenSSL) |
| Ciphersuite selection for PSK | TLSCipherPSK13 | Valid OpenSSL 1.1.1 cipher strings for TLS 1.3 protocol (their values are passed to the OpenSSL function <code>SSL_CTX_set_ciphersuites()</code>). | PSK-based ciphersuite selection criteria for TLS 1.3 Only OpenSSL 1.1.1 or newer. |
| | TLSCipherPSK | Valid OpenSSL cipher strings for TLS 1.2 or valid GnuTLS priority strings . Their values are passed to the <code>SSL_CTX_set_cipher_list()</code> or <code>gnutls_priority_init()</code> functions, respectively. | PSK-based ciphersuite selection criteria for TLS 1.2/1.3 (GnuTLS), TLS 1.2 (OpenSSL) |
| Combined ciphersuite list for certificate and PSK | TLSCipherAll13 | Valid OpenSSL 1.1.1 cipher strings for TLS 1.3 protocol (their values are passed to the OpenSSL function <code>SSL_CTX_set_ciphersuites()</code>). | Ciphersuite selection criteria for TLS 1.3 Only OpenSSL 1.1.1 or newer. |
| | TLSCipherAll | Valid OpenSSL cipher strings for TLS 1.2 or valid GnuTLS priority strings . Their values are passed to the <code>SSL_CTX_set_cipher_list()</code> or <code>gnutls_priority_init()</code> functions, respectively. | Ciphersuite selection criteria for TLS 1.2/1.3 (GnuTLS), TLS 1.2 (OpenSSL) |

To override the ciphersuite selection in `zabbix_get` and `zabbix_sender` utilities - use the command-line parameters:

- `--tls-cipher13`
- `--tls-cipher`

The new parameters are optional. If a parameter is not specified, the internal default value is used. If a parameter is defined it cannot be empty.

If the setting of a TLSCipher* value in the crypto library fails then the server, proxy or agent will not start and an error is logged.

It is important to understand when each parameter is applicable.

Outgoing connections

The simplest case is outgoing connections:

- For outgoing connections with certificate - use TLSCipherCert13 or TLSCipherCert
- For outgoing connections with PSK - use TLSCipherPSK13 or TLSCipherPSK
- In case of `zabbix_get` and `zabbix_sender` utilities the command-line parameters `--tls-cipher13` or `--tls-cipher` can be used (encryption is unambiguously specified with a `--tls-connect` parameter)

Incoming connections

It is a bit more complicated with incoming connections because rules are specific for components and configuration.

For Zabbix **agent**:

| Agent connection setup | Cipher configuration |
|------------------------|--------------------------------|
| TLSCConnect=cert | TLSCipherCert, TLSCipherCert13 |
| TLSCConnect=psk | TLSCipherPSK, TLSCipherPSK13 |
| TLSAccept=cert | TLSCipherCert, TLSCipherCert13 |
| TLSAccept=psk | TLSCipherPSK, TLSCipherPSK13 |

| Agent connection setup | Cipher configuration |
|------------------------|------------------------------|
| TLSAccept=cert,psk | TLSCipherAll, TLSCipherAll13 |

For Zabbix **server** and **proxy**:

| Connection setup | Cipher configuration |
|---|------------------------------|
| Outgoing connections using PSK | TLSCipherPSK, TLSCipherPSK13 |
| Incoming connections using certificates | TLSCipherAll, TLSCipherAll13 |
| Incoming connections using PSK if server has no certificate | TLSCipherPSK, TLSCipherPSK13 |
| Incoming connections using PSK if server has certificate | TLSCipherAll, TLSCipherAll13 |

Some pattern can be seen in the two tables above:

- TLSCipherAll and TLSCipherAll13 can be specified only if a combined list of certificate- **and** PSK-based ciphersuites is used. There are two cases when it takes place: server (proxy) with a configured certificate (PSK ciphersuites are always configured on server, proxy if crypto library supports PSK), agent configured to accept both certificate- and PSK-based incoming connections
- in other cases TLSCipherCert* and/or TLSCipherPSK* are sufficient

The following tables show the TLSCipher* built-in default values. They could be a good starting point for your own custom values.

| Parameter | GnuTLS 3.6.12 |
|---------------|--|
| TLSCipherCert | NONE:+VERS-TLS1.2:+ECDHE-RSA:+RSA:+AES-128-GCM:+AES-128-CBC:+AEAD:+SHA256:+SHA1:+CURVE-ALL:+COMP-NULL:+SIGN-ALL:+CTYPE-X.509 |
| TLSCipherPSK | NONE:+VERS-TLS1.2:+ECDHE-PSK:+PSK:+AES-128-GCM:+AES-128-CBC:+AEAD:+SHA256:+SHA1:+CURVE-ALL:+COMP-NULL:+SIGN-ALL |
| TLSCipherAll | NONE:+VERS-TLS1.2:+ECDHE-RSA:+RSA:+ECDHE-PSK:+PSK:+AES-128-GCM:+AES-128-CBC:+AEAD:+SHA256:+SHA1:+CURVE-ALL:+COMP-NULL:+SIGN-ALL:+CTYPE-X.509 |

| Parameter | OpenSSL 1.1.1d ¹ |
|-----------------|--|
| TLSCipherCert13 | |
| TLSCipherCert | EECDH+aRSA+AES128:RSA+aRSA+AES128 |
| TLSCipherPSK13 | TLS_CHACHA20_POLY1305_SHA256:TLS_AES_128_GCM_SHA256 |
| TLSCipherPSK | kECDHEPSK+AES128:kPSK+AES128 |
| TLSCipherAll13 | |
| TLSCipherAll | EECDH+aRSA+AES128:RSA+aRSA+AES128:kECDHEPSK+AES128:kPSK+AES128 |

¹ Default values are different for older OpenSSL versions (1.0.1, 1.0.2, 1.1.0), for LibreSSL and if OpenSSL is compiled without PSK support.

Examples of user-configured ciphersuites

See below the following examples of user-configured ciphersuites:

- [Testing cipher strings and allowing only PFS ciphersuites](#)
- [Switching from AES128 to AES256](#)

Testing cipher strings and allowing only PFS ciphersuites

To see which ciphersuites have been selected you need to set 'DebugLevel=4' in the configuration file, or use the -vv option for zabbix_sender.

Some experimenting with TLSCipher* parameters might be necessary before you get the desired ciphersuites. It is inconvenient to restart Zabbix server, proxy or agent multiple times just to tweak TLSCipher* parameters. More convenient options are using zabbix_sender or the openssl command. Let's show both.

1. Using zabbix_sender.

Let's make a test configuration file, for example /home/zabbix/test.conf, with the syntax of a zabbix_agentd.conf file:

```

Hostname=nonexisting
ServerActive=nonexisting

TLSConnect=cert
TLSCAFile=/home/zabbix/ca.crt
TLSCertFile=/home/zabbix/agent.crt
TLSKeyFile=/home/zabbix/agent.key
TLSPSKIdentity=nonexisting
TLSPSKFile=/home/zabbix/agent.psk

```

You need valid CA and agent certificates and PSK for this example. Adjust certificate and PSK file paths and names for your environment.

If you are not using certificates, but only PSK, you can make a simpler test file:

```

Hostname=nonexisting
ServerActive=nonexisting

TLSConnect=psk
TLSPSKIdentity=nonexisting
TLSPSKFile=/home/zabbix/agentd.psk

```

The selected ciphersuites can be seen by running `zabbix_sender` (example compiled with OpenSSL 1.1.d):

```

$ zabbix_sender -vv -c /home/zabbix/test.conf -k nonexisting_item -o 1 2>&1 | grep ciphersuites
zabbix_sender [41271]: DEBUG: zbx_tls_init_child() certificate ciphersuites: TLS_AES_256_GCM_SHA384 TLS_
zabbix_sender [41271]: DEBUG: zbx_tls_init_child() PSK ciphersuites: TLS_CHACHA20_POLY1305_SHA256 TLS_AE
zabbix_sender [41271]: DEBUG: zbx_tls_init_child() certificate and PSK ciphersuites: TLS_AES_256_GCM_SHA

```

Here you see the ciphersuites selected by default. These default values are chosen to ensure interoperability with Zabbix agents running on systems with older OpenSSL versions (from 1.0.1).

With newer systems you can choose to tighten security by allowing only a few ciphersuites, e.g. only ciphersuites with PFS (Perfect Forward Secrecy). Let's try to allow only ciphersuites with PFS using `TLSCipher*` parameters.

Attention:

The result will not be interoperable with systems using OpenSSL 1.0.1 and 1.0.2, if PSK is used. Certificate-based encryption should work.

Add two lines to the `test.conf` configuration file:

```

TLSCipherCert=EECDH+aRSA+AES128
TLSCipherPSK=kECDHEPSK+AES128

```

and test again:

```

$ zabbix_sender -vv -c /home/zabbix/test.conf -k nonexisting_item -o 1 2>&1 | grep ciphersuites
zabbix_sender [42892]: DEBUG: zbx_tls_init_child() certificate ciphersuites: TLS_AES_256_GCM_SHA384 TLS_
zabbix_sender [42892]: DEBUG: zbx_tls_init_child() PSK ciphersuites: TLS_CHACHA20_POLY1305_SHA256 TLS_AE
zabbix_sender [42892]: DEBUG: zbx_tls_init_child() certificate and PSK ciphersuites: TLS_AES_256_GCM_SHA

```

The "certificate ciphersuites" and "PSK ciphersuites" lists have changed - they are shorter than before, only containing TLS 1.3 ciphersuites and TLS 1.2 ECDHE-* ciphersuites as expected.

2. `TLSCipherAll` and `TLSCipherAll13` cannot be tested with `zabbix_sender`; they do not affect "certificate and PSK ciphersuites" value shown in the example above. To tweak `TLSCipherAll` and `TLSCipherAll13` you need to experiment with the agent, proxy or server.

So, to allow only PFS ciphersuites you may need to add up to three parameters

```

TLSCipherCert=EECDH+aRSA+AES128
TLSCipherPSK=kECDHEPSK+AES128
TLSCipherAll=EECDH+aRSA+AES128:kECDHEPSK+AES128

```

to `zabbix_agentd.conf`, `zabbix_proxy.conf` and `zabbix_server.conf` if each of them has a configured certificate and agent has also PSK.

If your Zabbix environment uses only PSK-based encryption and no certificates, then only one:

```

TLSCipherPSK=kECDHEPSK+AES128

```

Now that you understand how it works you can test the ciphersuite selection even outside of Zabbix, with the `openssl` command. Let's test all three `TLSCipher*` parameter values:

```
$ openssl ciphers ECDH+aRSA+AES128 | sed 's:/ /g'
TLS_AES_256_GCM_SHA384 TLS_CHACHA20_POLY1305_SHA256 TLS_AES_128_GCM_SHA256 ECDHE-RSA-AES128-GCM-SHA256 GR
$ openssl ciphers kECDHEPSK+AES128 | sed 's:/ /g'
TLS_AES_256_GCM_SHA384 TLS_CHACHA20_POLY1305_SHA256 TLS_AES_128_GCM_SHA256 ECDHE-PSK-AES128-CBC-SHA256 GR
$ openssl ciphers ECDH+aRSA+AES128:kECDHEPSK+AES128 | sed 's:/ /g'
TLS_AES_256_GCM_SHA384 TLS_CHACHA20_POLY1305_SHA256 TLS_AES_128_GCM_SHA256 ECDHE-RSA-AES128-GCM-SHA256 GR
```

You may prefer `openssl ciphers` with option `-V` for a more verbose output:

```
$ openssl ciphers -V ECDH+aRSA+AES128:kECDHEPSK+AES128
0x13,0x02 - TLS_AES_256_GCM_SHA384 TLSv1.3 Kx=any Au=any Enc=AESGCM(256) Mac=AEAD
0x13,0x03 - TLS_CHACHA20_POLY1305_SHA256 TLSv1.3 Kx=any Au=any Enc=CHACHA20/POLY1305(256) Mac=AEAD
0x13,0x01 - TLS_AES_128_GCM_SHA256 TLSv1.3 Kx=any Au=any Enc=AESGCM(128) Mac=AEAD
0xC0,0x2F - ECDHE-RSA-AES128-GCM-SHA256 TLSv1.2 Kx=ECDH Au=RSA Enc=AESGCM(128) Mac=AEAD
0xC0,0x27 - ECDHE-RSA-AES128-SHA256 TLSv1.2 Kx=ECDH Au=RSA Enc=AES(128) Mac=SHA256
0xC0,0x13 - ECDHE-RSA-AES128-SHA TLSv1 Kx=ECDH Au=RSA Enc=AES(128) Mac=SHA1
0xC0,0x37 - ECDHE-PSK-AES128-CBC-SHA256 TLSv1 Kx=ECDHEPSK Au=PSK Enc=AES(128) Mac=SHA256
0xC0,0x35 - ECDHE-PSK-AES128-CBC-SHA TLSv1 Kx=ECDHEPSK Au=PSK Enc=AES(128) Mac=SHA1
```

Similarly, you can test the priority strings for GnuTLS:

```
$ gnutls-cli -l --priority=NONE:+VERS-TLS1.2:+ECDHE-RSA:+AES-128-GCM:+AES-128-CBC:+AEAD:+SHA256:+CURVE-ALL:+COMP-ALL
Cipher suites for NONE:+VERS-TLS1.2:+ECDHE-RSA:+AES-128-GCM:+AES-128-CBC:+AEAD:+SHA256:+CURVE-ALL:+COMP-ALL:
TLS_ECDHE_RSA_AES_128_GCM_SHA256 0xc0, 0x2f TLS1.2
TLS_ECDHE_RSA_AES_128_CBC_SHA256 0xc0, 0x27 TLS1.2
```

```
Protocols: VERS-TLS1.2
Ciphers: AES-128-GCM, AES-128-CBC
MACs: AEAD, SHA256
Key Exchange Algorithms: ECDHE-RSA
Groups: GROUP-SECP256R1, GROUP-SECP384R1, GROUP-SECP521R1, GROUP-X25519, GROUP-X448, GROUP-FFDHE2048, GROUP-FFDHE3072
PK-signatures: SIGN-RSA-SHA256, SIGN-RSA-PSS-SHA256, SIGN-RSA-PSS-RSAE-SHA256, SIGN-ECDSA-SHA256, SIGN-ECDSA-SHA384, SIGN-ECDSA-SHA512
```

Switching from AES128 to AES256

Zabbix uses AES128 as the built-in default for data. Let's assume you are using certificates and want to switch to AES256, on OpenSSL 1.1.1.

This can be achieved by adding the respective parameters in `zabbix_server.conf`:

```
TLSCAFile=/home/zabbix/ca.crt
TLSCertFile=/home/zabbix/server.crt
TLSKeyFile=/home/zabbix/server.key
TLSCipherCert13=TLS_AES_256_GCM_SHA384
TLSCipherCert=EECDH+aRSA+AES256:-SHA1:-SHA384
TLSCipherPSK13=TLS_CHACHA20_POLY1305_SHA256
TLSCipherPSK=kECDHEPSK+AES256:-SHA1
TLSCipherAll13=TLS_AES_256_GCM_SHA384
TLSCipherAll=EECDH+aRSA+AES256:-SHA1:-SHA384
```

Attention:

Although only certificate-related ciphersuites will be used, `TLSCipherPSK*` parameters are defined as well to avoid their default values which include less secure ciphers for wider interoperability. PSK ciphersuites cannot be completely disabled on server/proxy.

And in `zabbix_agentd.conf`:

```
TLSConnect=cert
TLSAccept=cert
TLSCAFile=/home/zabbix/ca.crt
TLSCertFile=/home/zabbix/agent.crt
TLSKeyFile=/home/zabbix/agent.key
TLSCipherCert13=TLS_AES_256_GCM_SHA384
TLSCipherCert=EECDH+aRSA+AES256:-SHA1:-SHA384
```

1 Using certificates

Overview

Zabbix can use RSA certificates in PEM format, signed by a public or an in-house certificate authority (CA).
Certificate verification is performed against a pre-configured CA certificate. Optionally, [Certificate Revocation Lists \(CRL\)](#) can be used.
Each Zabbix component can have only one certificate configured.
For more information on setting up and operating an internal CA, generating and signing certificate requests, and revoking certificates, refer to tutorials such as the [OpenSSL PKI Tutorial v2.0](#).
Carefully consider and test your certificate extensions. For more details, see [Limitations on using X.509 v3 certificate extensions](#).

Certificate configuration parameters

The following configuration parameters are supported for setting up certificates on Zabbix components.

| Parameter | Mandatory | Description |
|-----------------------------|-----------|--|
| <i>TLSCAFile</i> | yes | Full pathname of a file containing the top-level CA(s) certificates for peer certificate verification. If using a certificate chain with multiple members, order the certificates with lower level CA(s) certificates first, followed by higher level CA(s) certificates. Certificates from multiple CAs can be included in a single file. |
| <i>TLSCRLFile</i> | no | Full pathname of a file containing Certificate Revocation Lists (CRL) . |
| <i>TLSCertFile</i> | yes | Full pathname of a file containing the certificate. If using a certificate chain with multiple members, order the certificates with the server, proxy, or agent certificate first, followed by lower level CA(s) certificates, and concluded by higher level CA(s) certificates. |
| <i>TLSKeyFile</i> | yes | Full pathname of a file containing the private key. Ensure that this file is readable only by the Zabbix user by setting appropriate access rights. |
| <i>TLSServerCertIssuer</i> | no | Allowed server certificate issuer. |
| <i>TLSServerCertSubject</i> | no | Allowed server certificate subject. |

Configuration examples

After setting up the necessary certificates, configure Zabbix components to use certificate-based encryption.
Below are detailed steps for configuring:

- [Zabbix server](#)
- [Zabbix proxy](#)
- [Zabbix agent](#)

Zabbix server

1. Prepare the CA certificate file.

In order to verify peer certificates, Zabbix server must have access to the file containing the top-level, self-signed root CA certificates. For example, if certificates from two independent root CAs are needed, place them into a file at `/home/zabbix/zabbix_ca_file.crt`

```
Certificate:
Data:
  Version: 3 (0x2)
  Serial Number: 1 (0x1)
Signature Algorithm: sha1WithRSAEncryption
  Issuer: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Root1 CA
  ...
  Subject: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Root1 CA
  Subject Public Key Info:
    Public Key Algorithm: rsaEncryption
    Public-Key: (2048 bit)
    ...
  X509v3 extensions:
```

```

        X509v3 Key Usage: critical
            Certificate Sign, CRL Sign
        X509v3 Basic Constraints: critical
            CA:TRUE
    ...
-----BEGIN CERTIFICATE-----
MIID2jCCAsKgAwIBAgIBATANBgkqhkiG9w0BAQUFADB+MRMwEQYKCZImiZPyLGGQ
....
9wEzdN8uTrqoyU78gi12npLj08LegRKjb5hFTVm0
-----END CERTIFICATE-----
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 1 (0x1)
    Signature Algorithm: sha1WithRSAEncryption
        Issuer: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Root2 CA
    ...
    Subject: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Root2 CA
    Subject Public Key Info:
        Public Key Algorithm: rsaEncryption
        Public-Key: (2048 bit)
    ....
    X509v3 extensions:
        X509v3 Key Usage: critical
            Certificate Sign, CRL Sign
        X509v3 Basic Constraints: critical
            CA:TRUE
    ....
-----BEGIN CERTIFICATE-----
MIID3DCCAsSgAwIBAgIBATANBgkqhkiG9w0BAQUFADB/MRMwEQYKCZImiZPyLGGQ
...
vdGNYoSfvu41GQAR5Vj5FnRJRzv5XQOZ3B6894GY1zY=
-----END CERTIFICATE-----

```

2. Place the Zabbix server certificate/certificate chain into a file, for example, at `/home/zabbix/zabbix_server.crt`. The first certificate is the Zabbix server certificate, followed by the intermediate CA certificate:

```

Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 1 (0x1)
    Signature Algorithm: sha1WithRSAEncryption
        Issuer: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Signing CA
    ...
    Subject: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Zabbix server
    Subject Public Key Info:
        Public Key Algorithm: rsaEncryption
        Public-Key: (2048 bit)
    ...
    X509v3 extensions:
        X509v3 Key Usage: critical
            Digital Signature, Key Encipherment
        X509v3 Basic Constraints:
            CA:FALSE
    ...
-----BEGIN CERTIFICATE-----
MIIECDCAvCgAwIBAgIBATANBgkqhkiG9w0BAQUFADCBgTETMBEGCgmSJomT8ixk
...
h02u1GHiy46GI+xfR3LsPwFKlkTaaLaL/6aaoQ==
-----END CERTIFICATE-----
Certificate:
    Data:
        Version: 3 (0x2)

```

```

    Serial Number: 2 (0x2)
    Signature Algorithm: sha1WithRSAEncryption
    Issuer: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Root1 CA
    ...
    Subject: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Signing CA
    Subject Public Key Info:
        Public Key Algorithm: rsaEncryption
        Public-Key: (2048 bit)
        ...
    X509v3 extensions:
        X509v3 Key Usage: critical
            Certificate Sign, CRL Sign
        X509v3 Basic Constraints: critical
            CA:TRUE, pathlen:0
    ...
-----BEGIN CERTIFICATE-----
MIID4TCCAsmgAwIBAgIBAJANBgkqhkiG9w0BAQUFADB+MRMwEQYKCZImiZPyLGGQ
...
dyCeWnvL7u5sd6ffo8iRny0QzbHKmQt/wUtcVIvWXdmIFJMOHw==
-----END CERTIFICATE-----

```

Note:

Use only the attributes mentioned above for both client and server certificates to avoid affecting the certificate verification process. For example, OpenSSL might fail to establish an encrypted connection if *X509v3 Subject Alternative Name* or *Netscape Cert Type* extensions are used. For more information, see [Limitations on using X.509 v3 certificate extensions](#).

3. Place the Zabbix server private key into a file, for example, at `/home/zabbix/zabbix_server.key`:

```

-----BEGIN PRIVATE KEY-----
MIIEwAIBADANBgkqhkiG9w0BAQEFAASCBAKowggSMAgEAAoIBAQC9tIXIJoVnNXDl
...
IJLkhbybBYEf47MLhffWa7XvZTY=
-----END PRIVATE KEY-----

```

4. Edit the TLS configuration parameters in the **Zabbix server configuration file**:

```

TLSCAFile=/home/zabbix/zabbix_ca_file
TLSCertFile=/home/zabbix/zabbix_server.crt
TLSKeyFile=/home/zabbix/zabbix_server.key

```

Zabbix proxy

1. Prepare files with the top-level CA certificates, the Zabbix proxy certificate/certificate chain, and the private key as described in the **Zabbix server** section. Then, edit the `TLSCAFile`, `TLSCertFile`, and `TLSKeyFile` parameters in the **Zabbix proxy configuration file** accordingly.

2. Edit additional TLS parameters in the **Zabbix proxy configuration file**:

- For active proxy: `TLSConnect=cert`
- For passive proxy: `TLSAccept=cert`

Note:

To improve proxy security, you can also set the `TLSServerCertIssuer` and `TLSServerCertSubject` parameters. For more information, see [Restricting allowed certificate issuer and subject](#).

TLS parameters in the final proxy configuration file may look as follows:

```

TLSConnect=cert
TLSAccept=cert
TLSCAFile=/home/zabbix/zabbix_ca_file
TLSServerCertIssuer=CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
TLSServerCertSubject=CN=Zabbix server,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
TLSCertFile=/home/zabbix/zabbix_proxy.crt
TLSKeyFile=/home/zabbix/zabbix_proxy.key

```

3. Configure encryption for this proxy in Zabbix frontend:

- Go to: *Administration* → *Proxies*.
- Select the proxy and click the *Encryption* tab.

In the examples below, the *Issuer* and *Subject* fields are filled in. For more information on why and how to use these fields, see [Restricting allowed certificate issuer and subject](#).

For active proxy:

The screenshot shows the 'Proxy' configuration window with the 'Encryption' tab selected. Under 'Connections to proxy', the 'Certificate' button is highlighted. Under 'Connections from proxy', the 'Certificate' checkbox is checked. The 'Issuer' field contains 'CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com' and the 'Subject' field contains 'CN=www01,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com'. At the bottom are buttons for 'Update', 'Refresh configuration', 'Clone', 'Delete', and 'Cancel'.

For passive proxy:

The screenshot shows the 'Proxy' configuration window with the 'Encryption' tab selected. Under 'Connections to proxy', the 'Certificate' button is highlighted. Under 'Connections from proxy', the 'No encryption' checkbox is checked. The 'Issuer' field contains 'CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com' and the 'Subject' field contains 'CN=www01,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com'. At the bottom are buttons for 'Update', 'Refresh configuration', 'Clone', 'Delete', and 'Cancel'.

Zabbix agent

1. Prepare files with the top-level CA certificates, the Zabbix agent certificate/certificate chain, and the private key as described in the [Zabbix server](#) section. Then, edit the `TLSCAFile`, `TLSCertFile`, and `TLSKeyFile` parameters in the [Zabbix agent configuration file](#) accordingly.
2. Edit additional TLS parameters in the [Zabbix agent configuration file](#):
 - For active agent: `TLSConnect=cert`
 - For passive agent: `TLSAccept=cert`

Note:

To improve agent security, you can set the `TLSServerCertIssuer` and `TLSServerCertSubject` parameters. For more information, see [Restricting allowed certificate issuer and subject](#).

The TLS parameters in the final agent configuration file may look as follows. Note that the example assumes that the host is monitored by a proxy, hence it is specified as the certificate Subject:

```

TLSConnect=cert
TLSAccept=cert
TLSCAFile=/home/zabbix/zabbix_ca_file

```

```
TLSServerCertIssuer=CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
TLSServerCertSubject=CN=Zabbix proxy,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
TLSCertFile=/home/zabbix/zabbix_agentd.crt
TLSKeyFile=/home/zabbix/zabbix_agentd.key
```

3. Configure encryption in Zabbix frontend for the host monitored by this agent.

- Go to: *Data collection* → *Hosts*.
- Select the host and click the *Encryption* tab.

In the example below, the *Issuer* and *Subject* fields are filled in. For more information on why and how to use these fields, see [Restricting allowed certificate issuer and subject](#).

The screenshot shows the 'Host' configuration window in Zabbix, specifically the 'Encryption' tab. The 'Connections to host' section has three buttons: 'No encryption', 'PSK', and 'Certificate', with 'Certificate' being the active selection. The 'Connections from host' section has three checkboxes: 'No encryption', 'PSK', and 'Certificate', with 'Certificate' being checked. Below these, there are two text input fields: 'Issuer' with the value 'CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com' and 'Subject' with the value 'CN=www01,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com'. At the bottom right, there are four buttons: 'Update', 'Clone', 'Delete', and 'Cancel'.

Zabbix web service

1. Prepare files with the top-level CA certificates, the Zabbix web service certificate/certificate chain, and the private key as described in the [Zabbix server](#) section. Then, edit the `TLSCAFile`, `TLSCertFile`, and `TLSKeyFile` parameters in the [Zabbix web service configuration file](#) accordingly.
2. Edit an additional TLS parameter in the [Zabbix web service configuration file](#): `TLSAccept=cert`

TLS parameters in the final web service configuration file may look as follows:

```
TLSAccept=cert
TLSCAFile=/home/zabbix/zabbix_ca_file
TLSCertFile=/home/zabbix/zabbix_web_service.crt
TLSKeyFile=/home/zabbix/zabbix_web_service.key
```

3. Configure Zabbix server to connect to the TLS-configured Zabbix web service by editing the `WebServiceURL` parameter in the [Zabbix server configuration file](#):

```
WebServiceURL=https://example.com
```

Restricting allowed certificate issuer and subject

When two Zabbix components (for example, server and agent) establish a TLS connection, they validate each other's certificates. If a peer certificate is signed by a trusted CA (with a pre-configured top-level certificate in `TLSCAFile`), is valid, has not expired, and passes other checks, then the communication between components can proceed. In this simplest case, the certificate issuer and subject are not verified.

However, this presents a risk: anyone with a valid certificate can impersonate anyone else (for example, a host certificate could be used to impersonate a server). While this may be acceptable in small environments where certificates are signed by a dedicated in-house CA and the risk of impersonation is low, it may not be sufficient in larger or more security-sensitive environments.

If your top-level CA issues certificates that should not be accepted by Zabbix or if you want to reduce the risk of impersonation, you can restrict allowed certificates by specifying their issuer and subject.

For example, in the Zabbix proxy configuration file, you could specify:

```
TLSServerCertIssuer=CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
TLSServerCertSubject=CN=Zabbix server,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
```

With these settings, an active proxy will not communicate with a Zabbix server whose certificate has a different issuer or subject. Similarly, a passive proxy will not accept requests from such a server.

Rules for matching Issuer and Subject strings

The rules for matching Issuer and Subject strings are as follows:

- Issuer and Subject strings are checked independently. Both are optional.
- An unspecified string means that any string is accepted.
- Strings are compared as *is* and must match exactly.
- UTF-8 characters are supported. However, wildcards (*) or regular expressions are not supported.
- The following [RFC 4514](#) requirements are implemented - characters that require escaping (with a '\' backslash, U+005C):
 - anywhere in the string: ' ' (U+0022), '+' (U+002B), ',' (U+002C), ';' (U+003B), '<' (U+003C), '>' (U+003E), '\\'
- at the beginning of the string: space (' ', U+0020) or number sign ('#', U+0023);
- at the end of the string: space (' ', U+0020).
- Null characters (U+0000) are not supported. If a null character is encountered, the matching will fail.
- [RFC 4517](#) and [RFC 4518](#) standards are not supported.

For example, if Issuer and Subject organization (O) strings contain trailing spaces and the Subject organizational unit (OU) string contains double quotes, these characters must be escaped:

```
TLSServerCertIssuer=CN=Signing CA,OU=Development head,O=\ Example SIA\ ,DC=example,DC=com
TLSServerCertSubject=CN=Zabbix server,OU=Development group \"5\",O=\ Example SIA\ ,DC=example,DC=com
```

Field order and formatting

Zabbix follows the recommendations of [RFC 4514](#), which specifies a “reverse” order for these fields, starting with the lowest-level fields (CN), proceeding to the mid-level fields (OU, O), and concluding with the highest-level fields (DC).

```
TLSServerCertIssuer=CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
TLSServerCertSubject=CN=Zabbix proxy,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
```

In contrast, OpenSSL by default displays the Issuer and Subject strings in top-level to low-level order. In the following example, Issuer and Subject fields start with the top-level (DC) and end with the low-level (CN) field. The formatting with spaces and field separators also varies based on the options used, and thus will not match the format required by Zabbix.

```
$ openssl x509 -noout -in /home/zabbix/zabbix_proxy.crt -issuer -subject
issuer= /DC=com/DC=zabbix/O=Zabbix SIA/OU=Development group/CN=Signing CA
subject= /DC=com/DC=zabbix/O=Zabbix SIA/OU=Development group/CN=Zabbix proxy

$ openssl x509 -noout -text -in /home/zabbix/zabbix_proxy.crt
Certificate:
    ...
    Issuer: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Signing CA
    ...
    Subject: DC=com, DC=zabbix, O=Zabbix SIA, OU=Development group, CN=Zabbix proxy
```

To format *Issuer* and *Subject* strings correctly for Zabbix, invoke OpenSSL with the following options:

```
$ openssl x509 -noout -issuer -subject \
-nameopt esc_2253,esc_ctrl,utf8,dump_nostr,dump_unknown,dump_der,sep_comma_plus,dn_rev,sname\
-in /home/zabbix/zabbix_proxy.crt
```

The output will then be in reverse order, comma-separated, and usable in Zabbix configuration files and frontend:

```
issuer= CN=Signing CA,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
subject= CN=Zabbix proxy,OU=Development group,O=Zabbix SIA,DC=zabbix,DC=com
```

Limitations on using X.509 v3 certificate extensions

When implementing X.509 v3 certificates within Zabbix, certain extensions may not be fully supported or could result in inconsistent behavior.

Subject Alternative Name extension

Zabbix does not support the *Subject Alternative Name* extension, which is used to specify alternative DNS names such as IP addresses or email addresses. Zabbix can only validate the value in the *Subject* field of the certificate (see [Restricting Allowed Certificate Issuer and Subject](#)). If certificates include the `subjectAltName` field, the outcome of certificate validation may vary depending on the specific crypto toolkits used to compile Zabbix components. As a result, Zabbix may either accept or reject certificates based on these combinations.

Extended Key Usage extension

Zabbix supports the *Extended Key Usage* extension. However, if used, it is generally required that both *clientAuth* (for TLS WWW client authentication) and *serverAuth* (for TLS WWW server authentication) attributes are specified. For example:

- In passive checks, where Zabbix agent operates as a TLS server, the *serverAuth* attribute must be included in the agent's certificate.
- For active checks, where the agent operates as a TLS client, the *clientAuth* attribute must be included in the agent's certificate.

While GnuTLS may issue a warning for key usage violations, it typically allows communication to proceed despite these warnings.

Name Constraints extension

Support for the *Name Constraints* extension varies among crypto toolkits. Ensure that your chosen toolkit supports this extension. This extension may restrict Zabbix from loading CA certificates if this section is marked as critical, depending on the specific toolkit in use.

Certificate Revocation Lists (CRL)

If a certificate is compromised, the Certificate Authority (CA) can revoke it by including the certificate in a Certificate Revocation List (CRL). CRLs are managed through configuration files and can be specified using the `TLSCRLFile` parameter in server, proxy, and agent configuration files. For example:

```
TLSCRLFile=/home/zabbix/zabbix_crl_file.crt
```

In this case, `zabbix_crl_file.crt` may contain CRLs from multiple CAs, and could look like this:

```
-----BEGIN X509 CRL-----
MIIB/DCB5QIBATANBgqhkiG9w0BAQUFADCBgTETMBEGCgmSJomT8ixkARkWA2Nv
...
treZeUPjb7LSmZ3K2hpbZN7So0ZcAoHQ3GWd9npuctg=
-----END X509 CRL-----
-----BEGIN X509 CRL-----
MIIB+TCB4gIBATANBgqhkiG9w0BAQUFADB/MRMwEQYKCZImiZPyLQGQBGryDY29t
...
CAEebS2CND3ShBedZ8YSil5906JvaDP61lR5lNs=
-----END X509 CRL-----
```

The CRL file is loaded only when Zabbix starts. To update the CRL, restart Zabbix.

Attention:

If Zabbix components are compiled with OpenSSL and CRLs are used, ensure that each top-level and intermediate CA in the certificate chains has a corresponding CRL (even if it is empty) included in the `TLSCRLFile`.

2 Using pre-shared keys

Overview

Each pre-shared key (PSK) in Zabbix actually is a pair of:

- non-secret PSK identity string,
- secret PSK string value.

PSK identity string is a non-empty UTF-8 string. For example, "PSK ID 001 Zabbix agentd". It is a unique name by which this specific PSK is referred to by Zabbix components. Do not put sensitive information in PSK identity string - it is transmitted over the network unencrypted.

PSK value is a hard to guess string of hexadecimal digits, for example, "e560cb0d918d26d31b4f642181f5f570ad89a390931102e5391d08327b".

Size limits

There are size limits for PSK identity and value in Zabbix, in some cases a crypto library can have lower limit:

| Component | PSK identity max size | PSK value min size | PSK value max size |
|---------------------------------|--|---|--|
| <i>Zabbix</i> | 128 UTF-8 characters | 128-bit (16-byte PSK, entered as 32 hexadecimal digits) | 2048-bit (256-byte PSK, entered as 512 hexadecimal digits) |
| <i>GnuTLS</i> | 128 bytes (may include UTF-8 characters) | - | 2048-bit (256-byte PSK, entered as 512 hexadecimal digits) |
| <i>OpenSSL 1.0.x, 1.1.0</i> | 127 bytes (may include UTF-8 characters) | - | 2048-bit (256-byte PSK, entered as 512 hexadecimal digits) |
| <i>OpenSSL 1.1.1</i> | 127 bytes (may include UTF-8 characters) | - | 512-bit (64-byte PSK, entered as 128 hexadecimal digits) |
| <i>OpenSSL 1.1.1a and later</i> | 127 bytes (may include UTF-8 characters) | - | 2048-bit (256-byte PSK, entered as 512 hexadecimal digits) |

Attention:

Zabbix frontend allows configuring up to 128-character long PSK identity string and 2048-bit long PSK regardless of crypto libraries used.

If some Zabbix components support lower limits, it is the user's responsibility to configure PSK identity and value with allowed length for these components.

Exceeding length limits results in communication failures between Zabbix components.

Before Zabbix server connects to agent using PSK, the server looks up the PSK identity and PSK value configured for that agent in database (actually in configuration cache). Upon receiving a connection the agent uses PSK identity and PSK value from its configuration file. If both parties have the same PSK identity string and PSK value the connection may succeed.

Attention:

Each PSK identity must be paired with only one value. It is the user's responsibility to ensure that there are no two PSKs with the same identity string but different values. Failing to do so may lead to unpredictable errors or disruptions of communication between Zabbix components using PSKs with this PSK identity string.

Generating PSK

For example, a 256-bit (32 bytes) PSK can be generated using the following commands:

- with *OpenSSL*:

```
$ openssl rand -hex 32
af8ced32dfe8714e548694e2d29e1a14ba6fa13f216cb35c19d0feb1084b0429
```

- with *GnuTLS*:

```
$ psktool -u psk_identity -p database.psk -s 32
Generating a random key for user 'psk_identity'
Key stored to database.psk
```

```
$ cat database.psk
psk_identity:9b8eafedfaae00cece62e85d5f4792c7d9c9bcc851b23216a1d300311cc4f7cb
```

Note that "psktool" above generates a database file with a PSK identity and its associated PSK. Zabbix expects just a PSK in the PSK file, so the identity string and colon (':') should be removed from the file.

Configuring PSK for server-agent communication (example)

On the agent host, write the PSK value into a file, for example, `/home/zabbix/zabbix_agentd.psk`. The file must contain PSK in the first text string, for example:

```
1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952
```

Set access rights to PSK file - it must be readable only by Zabbix user.

Edit TLS parameters in agent configuration file `zabbix_agentd.conf`, for example, set:

```
TLSCConnect=psk
TLSCAccept=psk
TLSPSKFile=/home/zabbix/zabbix_agentd.psk
```

```
TLSPSKIdentity=PSK 001
```

The agent will connect to server (active checks) and accept from server and zabbix_get only connections using PSK. PSK identity will be "PSK 001".

Restart the agent. Now you can test the connection using zabbix_get, for example:

```
zabbix_get -s 127.0.0.1 -k "system.cpu.load[all,avg1]" --tls-connect=psk --tls-psk-identity="PSK 001" --tl
```

(To minimize downtime see how to change connection type in [Connection encryption management](#)).

Configure PSK encryption for this agent in Zabbix frontend:

- Go to: *Data collection* → *Hosts*
- Select host and click on **Encryption** tab

Example:

The screenshot shows the 'Host' configuration window in Zabbix, specifically the 'Encryption' tab. The 'Connections to host' section has three buttons: 'No encryption', 'PSK' (which is selected and highlighted in dark grey), and 'Certificate'. The 'Connections from host' section has three radio buttons: 'No encryption', 'PSK' (which is selected), and 'Certificate'. Below these, there are two mandatory input fields marked with a red asterisk: '* PSK identity' with the value 'PSK 001' and '* PSK' with a long hexadecimal string '1f87b595725ac58dd977beef14b97461a7c1045b9a1c963065002c5473194952'. At the bottom right, there are four buttons: 'Update' (in blue), 'Clone', 'Delete', and 'Cancel'.

All mandatory input fields are marked with a red asterisk.

When configuration cache is synchronized with database the new connections will use PSK. Check server and agent logfiles for error messages.

Configuring PSK for server - active proxy communication (example)

On the proxy, write the PSK value into a file, for example, `/home/zabbix/zabbix_proxy.psk`. The file must contain PSK in the first text string, for example:

```
e560cb0d918d26d31b4f642181f5f570ad89a390931102e5391d08327ba434e9
```

Set access rights to PSK file - it must be readable only by Zabbix user.

Edit TLS parameters in proxy configuration file `zabbix_proxy.conf`, for example, set:

```
TLSCConnect=psk
TLSPSKFile=/home/zabbix/zabbix_proxy.psk
TLSPSKIdentity=PSK 002
```

The proxy will connect to server using PSK. PSK identity will be "PSK 002".

(To minimize downtime see how to change connection type in [Connection encryption management](#)).

Configure PSK for this proxy in Zabbix frontend. Go to *Administration* → *Proxies*, select the proxy, go to "Encryption" tab. In "Connections from proxy" mark PSK. Paste into "PSK identity" field "PSK 002" and "e560cb0d918d26d31b4f642181f5f570ad89a390931102e5391d083" into "PSK" field. Click "Update".

Restart proxy. It will start using PSK-based encrypted connections to server. Check server and proxy logfiles for error messages.

For a passive proxy the procedure is very similar. The only difference - set `TLSAccept=psk` in proxy configuration file and set "Connections to proxy" in Zabbix frontend to PSK.

3 Troubleshooting

General recommendations

- Start with understanding which component acts as a TLS client and which one acts as a TLS server in problem case. Zabbix server, proxies and agents, depending on interaction between them, all can work as TLS servers and clients. For example, Zabbix server connecting to agent for a passive check, acts as a TLS client. The agent is in role of TLS server. Zabbix agent, requesting a list of active checks from proxy, acts as a TLS client. The proxy is in role of TLS server. `zabbix_get` and `zabbix_sender` utilities always act as TLS clients.
- Zabbix uses mutual authentication. Each side verifies its peer and may refuse connection. For example, Zabbix server connecting to agent can close connection immediately if agent's certificate is invalid. And vice versa - Zabbix agent accepting a connection from server can close connection if server is not trusted by agent.
- Examine logfiles in both sides - in TLS client and TLS server. The side which refuses connection may log a precise reason why it was refused. Other side often reports rather general error (e.g. "Connection closed by peer", "connection was non-properly terminated").
- Sometimes misconfigured encryption results in confusing error messages in no way pointing to real cause. In subsections below we try to provide a (far from exhaustive) collection of messages and possible causes which could help in troubleshooting. Please note that different crypto toolkits (OpenSSL, GnuTLS) often produce different error messages in same problem situations. Sometimes error messages depend even on particular combination of crypto toolkits on both sides.

1 Connection type or permission problems

Server is configured to connect with PSK to agent but agent accepts only unencrypted connections

In server or proxy log (with *GnuTLS* 3.3.16)

```
Get value from agent failed: zbx_tls_connect(): gnutls_handshake() failed: \
-110 The TLS connection was non-properly terminated.
```

In server or proxy log (with *OpenSSL* 1.0.2c)

```
Get value from agent failed: TCP connection successful, cannot establish TLS to [[127.0.0.1]:10050]: \
Connection closed by peer. Check allowed connection types and access rights
```

One side connects with certificate but other side accepts only PSK or vice versa

In any log (with *GnuTLS*):

```
failed to accept an incoming connection: from 127.0.0.1: zbx_tls_accept(): gnutls_handshake() failed:\
-21 Could not negotiate a supported cipher suite.
```

In any log (with *OpenSSL* 1.0.2c):

```
failed to accept an incoming connection: from 127.0.0.1: TLS handshake returned error code 1:\
file .\ssl\s3_srvr.c line 1411: error:1408A0C1:SSL routines:ssl3_get_client_hello:no shared cipher:\
TLS write fatal alert "handshake failure"
```

Attempting to use Zabbix sender compiled with TLS support to send data to Zabbix server/proxy compiled without TLS

In connecting-side log:

Linux:

```
...In zbx_tls_init_child()
...OpenSSL library (version OpenSSL 1.1.1 11 Sep 2018) initialized
...
...In zbx_tls_connect(): psk_identity:"PSK test sender"
...End of zbx_tls_connect():FAIL error:'connection closed by peer'
...send value error: TCP successful, cannot establish TLS to [[localhost]:10051]: connection closed by peer
```

Windows:

```
...OpenSSL library (version OpenSSL 1.1.1a 20 Nov 2018) initialized
...
...In zbx_tls_connect(): psk_identity:"PSK test sender"
...zbx_psk_client_cb() requested PSK identity "PSK test sender"
...End of zbx_tls_connect():FAIL error:'SSL_connect() I/O error: [0x00000000] The operation completed successfully'
...send value error: TCP successful, cannot establish TLS to [[192.168.1.2]:10051]: SSL_connect() I/O error: [0x00000000] The operation completed successfully
```

In accepting-side log:

...failed to accept an incoming connection: from 127.0.0.1: support for TLS was not compiled in
One side connects with PSK but other side uses LibreSSL or has been compiled without encryption support
LibreSSL does not support PSK.

In connecting-side log:

...TCP successful, cannot establish TLS to [[192.168.1.2]:10050]: SSL_connect() I/O error: [0] Success

In accepting-side log:

...failed to accept an incoming connection: from 192.168.1.2: support for PSK was not compiled in

In Zabbix frontend:

Get value from agent failed: TCP successful, cannot establish TLS to [[192.168.1.2]:10050]: SSL_connect()

One side connects with PSK but other side uses OpenSSL with PSK support disabled

In connecting-side log:

...TCP successful, cannot establish TLS to [[192.168.1.2]:10050]: SSL_connect() set result code to SSL_ERROR

In accepting-side log:

...failed to accept an incoming connection: from 192.168.1.2: TLS handshake set result code to 1: file ssl

2 Certificate problems

OpenSSL used with CRLs and for some CA in the certificate chain its CRL is not included in TLSCRLFile

In TLS server log in case of *OpenSSL* peer:

failed to accept an incoming connection: from 127.0.0.1: TLS handshake with 127.0.0.1 returned error code
file s3_srvr.c line 3251: error:14089086: SSL routines:ssl3_get_client_certificate:certificate verify
TLS write fatal alert "unknown CA"

In TLS server log in case of *GnuTLS* peer:

failed to accept an incoming connection: from 127.0.0.1: TLS handshake with 127.0.0.1 returned error code
file rsa_pk1.c line 103: error:0407006A: rsa routines:RSA_padding_check_PKCS1_type_1:\n
block type is not 01 file rsa_eay.c line 705: error:04067072: rsa routines:RSA_EAY_PUBLIC_DECRYPT:padding

CRL expired or expires during server operation

OpenSSL, in server log:

- before expiration:

cannot connect to proxy "proxy-openssl-1.0.1e": TCP successful, cannot establish TLS to [[127.0.0.1]:20004]
SSL_connect() returned SSL_ERROR_SSL: file s3_clnt.c line 1253: error:14090086:\n
SSL routines:ssl3_get_server_certificate:certificate verify failed:\n
TLS write fatal alert "certificate revoked"

- after expiration:

cannot connect to proxy "proxy-openssl-1.0.1e": TCP successful, cannot establish TLS to [[127.0.0.1]:20004]
SSL_connect() returned SSL_ERROR_SSL: file s3_clnt.c line 1253: error:14090086:\n
SSL routines:ssl3_get_server_certificate:certificate verify failed:\n
TLS write fatal alert "certificate expired"

The point here is that with valid CRL a revoked certificate is reported as "certificate revoked". When CRL expires the error message changes to "certificate expired" which is quite misleading.

GnuTLS, in server log:

- before and after expiration the same:

cannot connect to proxy "proxy-openssl-1.0.1e": TCP successful, cannot establish TLS to [[127.0.0.1]:20004]
invalid peer certificate: The certificate is NOT trusted. The certificate chain is revoked.

Self-signed certificate, unknown CA

OpenSSL, in log:

```
error:'self signed certificate: SSL_connect() set result code to SSL_ERROR_SSL: file ../ssl/statem/statem_
line 1924: error:1416F086:SSL routines:tls_process_server_certificate:certificate verify failed:\
TLS write fatal alert "unknown CA"'
```

This was observed when server certificate by mistake had the same Issuer and Subject string, although it was signed by CA. Issuer and Subject are equal in top-level CA certificate, but they cannot be equal in server certificate. (The same applies to proxy and agent certificates.)

To check whether a certificate contains the same Issuer and Subject entries, run:

```
openssl x509 -in <yourcertificate.crt> -noout -text
```

It is acceptable for the root (top-level) certificate to have identical values for Issuer and Subject.

3 PSK problems

PSK contains an odd number of hex-digits

Proxy or agent does not start, message in the proxy or agent log:

```
invalid PSK in file "/home/zabbix/zabbix_proxy.psk"
```

PSK identity string longer than 128 bytes is passed to GnuTLS

In TLS client side log:

```
gnutls_handshake() failed: -110 The TLS connection was non-properly terminated.
```

In TLS server side log.

```
gnutls_handshake() failed: -90 The SRP username supplied is illegal.
```

Too long PSK value used with OpenSSL 1.1.1

In connecting-side log:

```
...OpenSSL library (version OpenSSL 1.1.1 11 Sep 2018) initialized
...
...In zbx_tls_connect(): psk_identity:"PSK 1"
...zbx_psk_client_cb() requested PSK identity "PSK 1"
...End of zbx_tls_connect():FAIL error:'SSL_connect() set result code to SSL_ERROR_SSL: file ssl\statem\ex
```

In accepting-side log:

```
...Message from 123.123.123.123 is missing header. Message ignored.
```

This problem typically arises when upgrading OpenSSL from 1.0.x or 1.1.0 to 1.1.1 and if the PSK value is longer than 512-bit (64-byte PSK, entered as 128 hexadecimal digits).

See also: [Value size limits](#)

18 Web interface

Overview For an easy access to Zabbix from anywhere and from any platform, the web-based interface is provided.

Note:

If using more than one frontend instance make sure that the locales and libraries (LDAP, SAML etc.) are installed and configured identically for all frontends.

Frontend help A help link  is provided in Zabbix frontend forms with direct links to the corresponding parts of the documentation.

1 Menu

Overview

A vertical menu in a sidebar provides access to various Zabbix frontend sections.

The menu is dark blue in the default theme.

Working with the menu

A global search box is located below the Zabbix logo.

The menu can be collapsed or hidden completely:

- To collapse, click on  next to Zabbix logo. In the collapsed menu only the icons are visible.

- To hide, click on  next to Zabbix logo. In the hidden menu everything is hidden.

Collapsed menu

When the menu is collapsed to icons only, a full menu reappears as soon as the mouse cursor is placed upon it. Note that it reappears over page content; to move page content to the right you have to click on the expand button. If the mouse cursor again is placed outside the full menu, the menu will collapse again after two seconds.

You can also make a collapsed menu reappear fully by hitting the Tab key. Hitting the Tab key repeatedly will allow to focus on the next menu element.

Hidden menu

Even when the menu is hidden completely, a full menu is just one mouse click away, by clicking on the burger icon . Note that it reappears over page content; to move page content to the right you have to unhide the menu by clicking on the show sidebar button.

Menu levels

There are up to three levels in the menu.

Context menus

In addition to the main menu, Zabbix provides context menus for **host**, **item**, and **event** for quick access to frequently used entities, such as the latest values, simple graph, configuration form, related scripts or external links.

The context menus are accessible by clicking on the host, item or problem/trigger name in supported locations.

1 Event menu

Overview

The event menu contains shortcuts to actions or frontend sections that are frequently required for an event.

The event menu can be opened by clicking on the event name.

Problem

Content

The event context menu has six sections: *View*, *Actions*, *Configuration*, *Problem*, *Links*, and *Scripts*. For the entities that are not configured, links are disabled and displayed in gray. The sections *Scripts* and *Links* are displayed if their entities are configured.

The *View* section contains links to:

- **Problems** - opens the list of unresolved problems of the underlying trigger;
- **History** - leads to the *Latest data* graph/item history for the underlying item(s). If a trigger uses several items, links will be available for each of them.

The *Actions* section is available in *Trigger overview* widgets only. It contains a link to:

- **Update problem** - opens the **problem update** screen.

The *Configuration* section contains links to the configuration of:

- **Trigger** that fired the problem;
- **Items** used in the trigger expression.

Note:

Note that configuration section is available only for Admin and Super admin users.

The *Problem* section contains the options to:

- **Mark as cause** - mark the problem as cause;
- **Mark selected as symptoms** - mark the selected problems as symptoms of this problem.

The *Links* section contains links to:

- access a configured **trigger URL**;
- access custom links configured in **Global scripts** (with scope 'Manual event action' and type 'URL');
- access a configured external ticket for the problem (see the *Include event menu entry* option when configuring **webhooks**).

The *Scripts* section contains links to execute a global **script** (with scope *Manual event action*). This feature may be handy for running scripts used for managing problem tickets in external systems.

Supported locations

The event context menu is accessible by clicking on a problem or event name in various frontend sections, for example:

- Dashboards **widgets**, such as *Problems* widget, *Trigger overview* widget, etc.
- Monitoring → **Problems**
- Monitoring → **Problems** → Event details
- Reports → **Top 100 triggers** (global scripts and access to external ticket are not supported in this location)

2 Host menu

Overview

The host menu contains shortcuts to actions or frontend sections that are frequently required for a host.

The host menu can be opened by clicking on the host name.

Content

The host context menu has four sections: *View*, *Configuration*, *Links*, and *Scripts*. For the entities that are not configured, links are disabled and displayed in gray color. The sections *Scripts* and *Links* are displayed if their entities are configured.

View section contains links to:

- **Dashboards** - opens widgets and graphs.
- **Problems** - opens the *Problems* section with the list of unresolved problems of the underlying trigger.
- **Latest data** - opens the *Latest data* section with the list of all the latest data of the current host.
- **Graphs** - opens simple graphs of the current host.
- **Web** - opens the link to the configured web scenarios.

- **Inventory** - opens the link to the inventory of the current host.

Configuration section contains links to:

- **Host** - configuration form of the current host.
- **Items** - the list of the current host items.
- **Triggers** - the list of the current host triggers.
- **Graphs** - simple graphs of the current host.
- **Discovery** - the list of low-level discovery rules of the current host.
- **Web** - the list of web scenarios of the current host.

Note:

Note that configuration section is available only for Admin and Super admin users.

Links section contains links to:

- access a configured **trigger URL**.
- access custom links configured in **Global scripts** (with scope *Manual host action* and type 'URL').

Scripts section allows to execute **global scripts** configured for the current host. These scripts need to have their scope defined as *Manual host action* to be available in the host menu.

Supported locations

The host menu is accessible by clicking on a host in various frontend sections, for example:

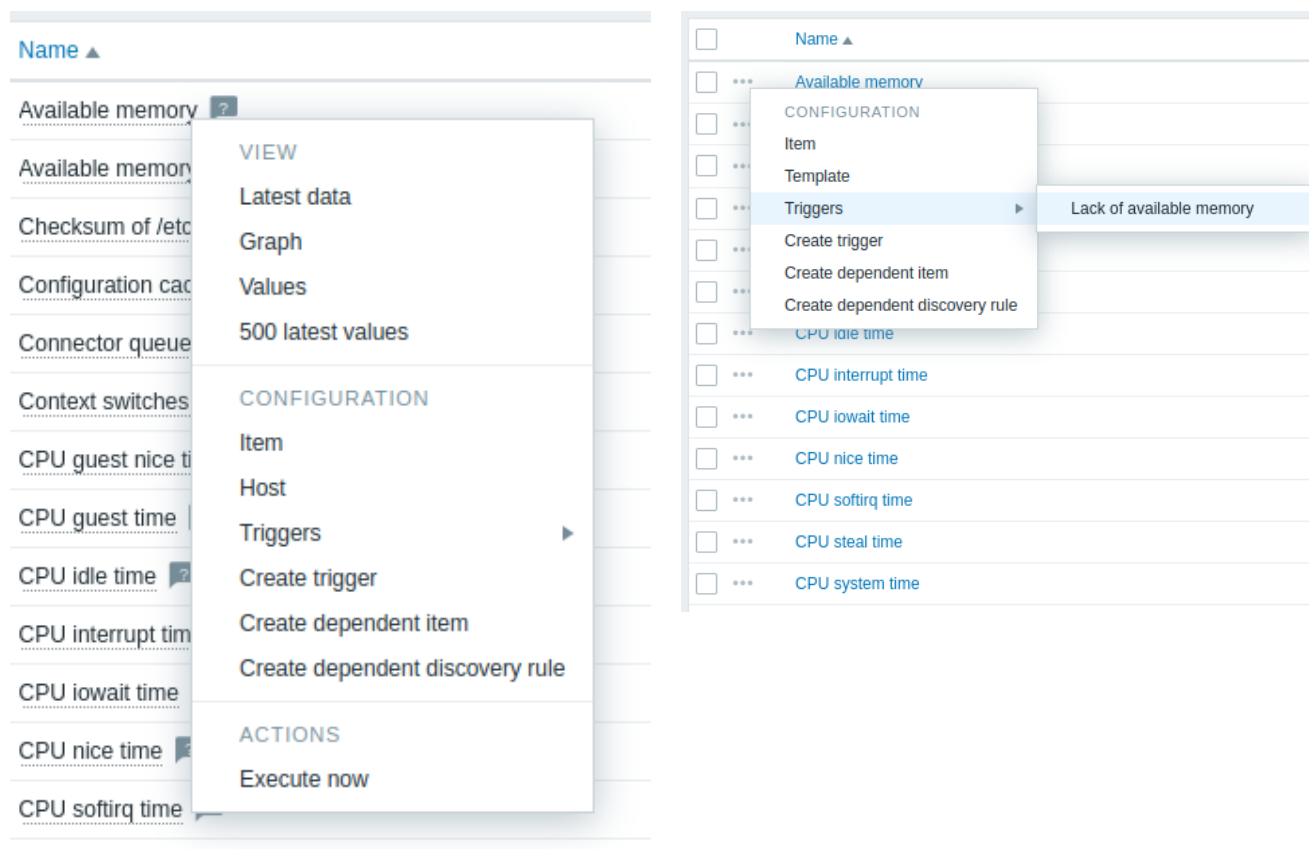

- Dashboards **widgets**, such as Problems, Top items, Trigger overview, etc.
- Monitoring → **Problems**
- Monitoring → **Problems** → Event details
- Monitoring → **Hosts**
- Monitoring → Hosts → **Web Monitoring**
- Monitoring → **Latest data**
- Monitoring → **Maps**
- Inventory → **Hosts**
- Reports → **Top 100 triggers**

3 Item menu

Overview

The item menu contains shortcuts to actions or frontend sections that are frequently required for an item.

The item menu can be opened by clicking on the item name or the three-dot icon, depending on the frontend section, for example:

Content

The item menu has three sections: *View*, *Configuration*, and *Actions*.

The *View* section contains the following options:

- **Latest data** - opens the *Latest data* section filtered by the current host and item;
- **Graph** - opens a *simple graph* of the current item;
- **Values** - opens the list of all *values* received for the current item within the past 60 minutes;
- **500 latest values** - opens the list of *500 latest values* for the current item.

The *Configuration* section (available only for *Admin* and *Super admin* type users) contains the following options:

- **Item** - opens the *item configuration form* of the current item;
- **Template** - opens the *template configuration form* of the template that the item belongs to (available only when the item menu is accessed from *Data collection → Templates → Items*);
- **Host** - opens the *host configuration form* of the host that the item belongs to;
- **Triggers** - on mouseover, opens a list of item's triggers, if any; clicking on a trigger opens its *trigger configuration form*;
- **Create trigger** - opens the *trigger configuration form* to create a trigger for this item;
- **Create dependent item** - opens the *item configuration form* to create a dependent item, with the current item as the master item;
- **Create dependent discovery rule** - opens the *discovery rule configuration form* to create a dependent discovery rule, with the current item as the master item.

The *Actions* section contains the following option:

- **Execute now** - *executes a check* for a new item value immediately.

Supported locations

The item menu is accessible by clicking on an item name in various frontend sections, for example:

- Monitoring → *Latest data*
- Data collection → Hosts → *Items*
- Data collection → Hosts → Discovery rules → *Item prototypes*

The item menu is accessible by clicking on an item value in the *Top items* dashboard widget.

2 Frontend sections

Menu structure The Zabbix frontend menu has the following structure:

- Dashboards
- Monitoring
 - Problems
 - Hosts
 - Latest data
 - Maps
 - Discovery
- Services
 - Services
 - SLA
 - SLA report
- Inventory
 - Overview
 - Hosts
- Reports

 - * Modules
 - * Other
 - Audit log

- Housekeeping
- Proxy groups
- Proxies
- Macros
- Queue
 - * Queue overview
 - * Queue overview by proxy
 - * Queue details

1 Dashboards

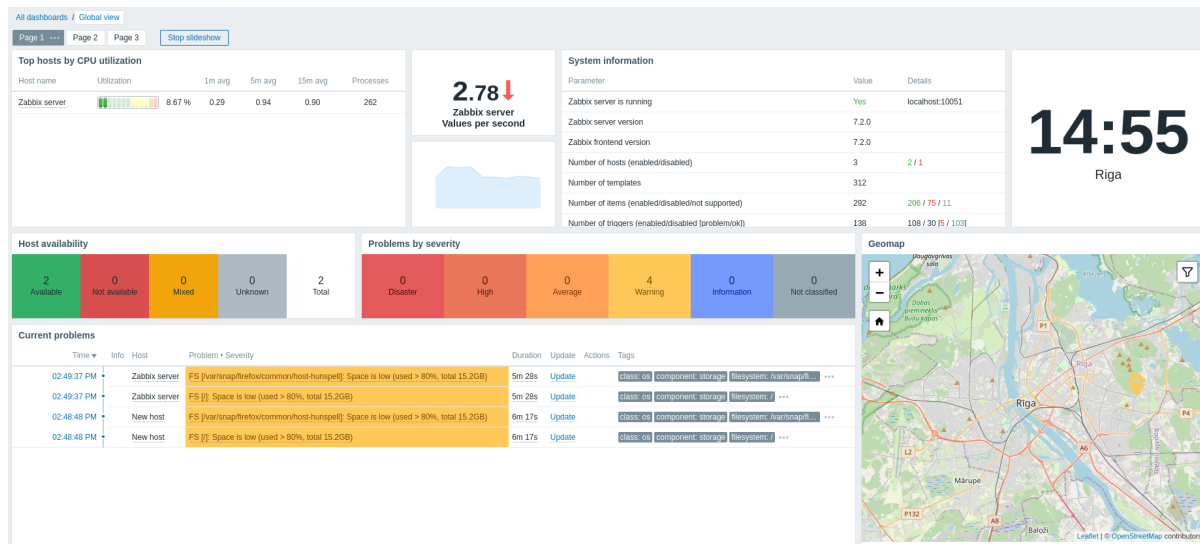

Overview

The *Dashboards* section is designed to display summaries of all the important information in a **dashboard**.

While only one dashboard can be displayed at one time, it is possible to configure several dashboards. Each dashboard may contain one or several pages that can be rotated in a slideshow.

A dashboard page consists of widgets and each widget is designed to display information of a certain kind and source, which can be a summary, a map, a graph, the clock, etc.

Access to hosts in the widgets depends on host **permissions**.

Pages and widgets are added to the dashboard and edited in the dashboard editing mode. Pages can be viewed and rotated in the dashboard viewing mode.

The time period that is displayed in graph widgets is controlled by the **Time period selector** located above the widgets. The *Time period* selector label, located to the right, displays the currently selected time period. Clicking the tab label allows expanding and collapsing the *Time period* selector.

Note that when the dashboard is displayed in kiosk mode and widgets only are displayed, it is possible to zoom out the graph period by double-clicking in the graph.

Dashboard size

The minimum width of a dashboard is 1200 pixels. The dashboard will not shrink below this width; instead a horizontal scrollbar is displayed if the browser window is smaller than that.

The maximum width of a dashboard is the browser window width. Dashboard widgets stretch horizontally to fit the window. At the same time, a dashboard widget cannot be stretched horizontally beyond the window limits.

Horizontally, the dashboard is made up of 72 columns of always equal width that stretch/shrink dynamically (but not to less than 1200 pixels total).

Vertically, the dashboard may contain a maximum of 64 rows; each row has a fixed height of 70 pixels.

A widget may be therefore be up to 72 columns wide and 64 rows high.

Viewing dashboards

To view all configured dashboards, click on *All dashboards* just below the section title.

| Filter  | | |
|--|----|--------|
| <input type="checkbox"/> Name ▲ | | |
| <input type="checkbox"/> Apache info | My | Shared |
| <input type="checkbox"/> Global view | My | Shared |
| <input type="checkbox"/> HyperV (John's custom) | My | |
| <input type="checkbox"/> Problems (quick view) | My | |
| <input type="checkbox"/> Zabbix server | My | Shared |
| <input type="checkbox"/> Zabbix server health | My | Shared |

Dashboards are displayed with a **sharing** tag:

- *My* - indicates a dashboard owned by the current user
- *Shared* - indicates a public dashboard or a private dashboard shared with any user or user group

Note that the sharing tags are shown for the dashboards owned by the current user only. The dashboards owned by other users are listed without sharing tags.

The filter located to the right above the list allows to filter dashboards by name and by those created by the current user.

To delete one or several dashboards, mark the checkboxes of the respective dashboards and click on *Delete* below the list.

Viewing a dashboard

To view a single dashboard, click on its name in the list of dashboards.

When **viewing** a dashboard, the following options are available:

Edit dashboard

Switch to the dashboard **editing** mode.

The editing mode is also opened when a new dashboard is being created and when you click on the  edit button of a widget.

Open the action menu (see action descriptions below).

| ACTIONS |
|----------------------|
| Sharing |
| Create new |
| Clone |
| Delete |
| Create new report |
| View related reports |

Sharing - edit **sharing preferences** for the dashboard.

Create new - **create** a new dashboard.

Clone - create a new dashboard by copying properties of the existing one. First you are prompted to enter dashboard parameters. Then, the new dashboard opens in editing mode with all the widgets of the original dashboard.

Delete - delete the dashboard.

Create new report - open a pop-up window with report **configuration form**. Disabled if the user does not have permission to manage scheduled reports.

View related reports - open a pop-up window with a list of existing reports based on the current dashboard. Disabled if there are no related reports or the user does not have permission to view scheduled reports.

Display only page content (**kiosk mode**).
Kiosk mode can also be accessed with the following URL parameters:
`/zabbix.php?action=dashboard.view&kiosk=1`.
To exit to normal mode: `/zabbix.php?action=dashboard.view&kiosk=0`

Sharing

Dashboards can be made public or private.

Public dashboards are visible to all users. Private dashboards are visible only to their owner and to the users/user groups added in the **sharing preferences**.

To edit the sharing status of a dashboard, click on the *Sharing* option in the action menu when viewing a single dashboard:

| Parameter | Description |
|----------------------------------|---|
| <i>Type</i> | Select dashboard type: Private - dashboard is visible only to selected user groups and users Public - dashboard is visible to all |
| <i>List of user group shares</i> | Select user groups that the dashboard is accessible to. |
| <i>List of user shares</i> | You may allow read-only or read-write access. Select users that the dashboard is accessible to. You may allow read-only or read-write access. |

See **Permissions to dashboards** to find out how sharing options limit the actions available to users.

Editing a dashboard

When **editing** a dashboard, the following options are available:

+

| |
|--------------|
| Add widget |
| Add page |
| Paste widget |
| Paste page |

Save

Cancel

Edit general dashboard **parameters**.
Add a new widget.
Clicking on the arrow button will open the action menu (see action descriptions below).

Add widget - add a new widget
Add page - add a new page
Paste widget - paste a copied widget. This option is grayed out if no widget has been copied.
Only one entity (widget or page) can be copied at one time.
Paste page - paste a copied page. This option is grayed out if no page has been copied.
Save dashboard changes.
Cancel dashboard changes.

Creating a dashboard

It is possible to create a new dashboard in two ways:

- Click on *Create dashboard*, when viewing all dashboards
- Select *Create new* from the action menu, when viewing a single dashboard

You will be first asked to enter general dashboard parameters:

Dashboard properties

* Owner

Admin (Zabbix Administrator) X

Select

* Name

New dashboard

Default page display period

30 seconds

▼

Start slideshow automatically

☒

Apply

Cancel

| Parameter | Description |
|--------------------------------------|---|
| <i>Owner</i> | Select system user that will be the dashboard owner. |
| <i>Name</i> | Enter dashboard name. |
| <i>Default page display period</i> | Select period for how long a dashboard page is displayed before rotating to the next page in a slideshow . |
| <i>Start slideshow automatically</i> | Mark this checkbox to run a slideshow automatically one more than one dashboard page exists. |

When you click on *Apply*, an empty dashboard is opened:

All dashboards / New dashboard

Page 1 ...

Add a new widget

To populate the dashboard, you can add widgets and pages.

Click on the *Save changes* button to save the dashboard. If you click on *Cancel*, the dashboard will not be created.

Adding widgets

You can add various **widgets** (Action log, Clock, Discovery status, etc.) to a dashboard. Widgets can be added in two ways:

- Click the *Add* button or the arrow next to it, then select *Add widget* from the action menu. After configuring the widget, it will be added in its default size and placed after any existing widget.

?

⚙

+ Add ▼

Add widget

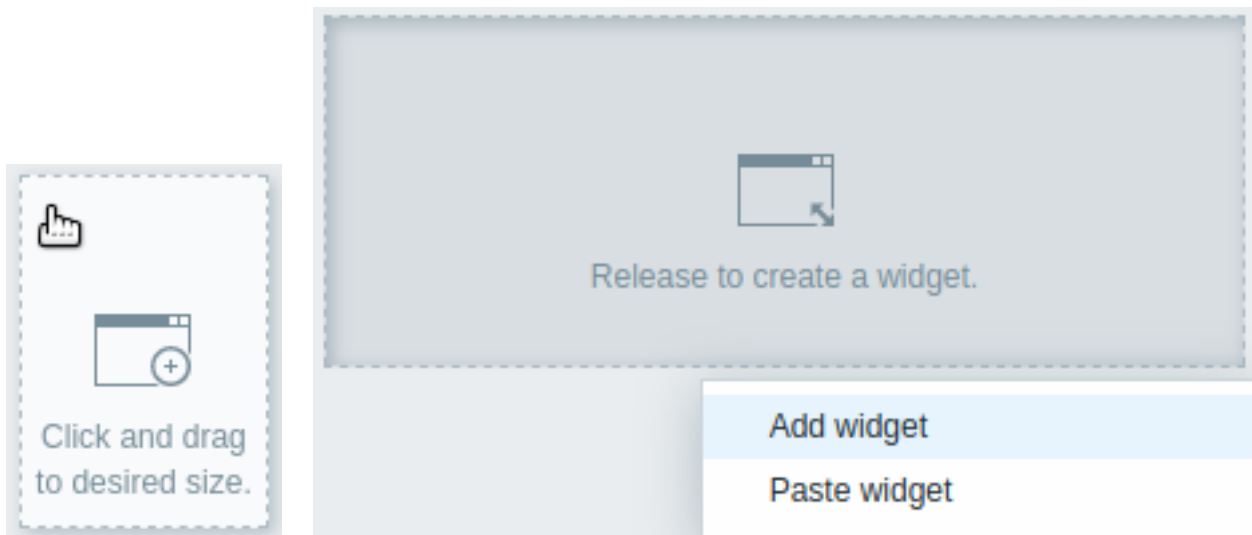

Add page

Paste widget

Paste page

- Move the mouse to an empty spot on the dashboard. Notice a placeholder appear, then click on it to open the widget configuration form. After configuring the widget, it will be added in its default size or resized to fit the available space.

Alternatively, drag the placeholder to determine the widget size and release it to open the widget configuration form (if a widget is **copied** to the clipboard, you will first be prompted to choose between *Add widget* or *Paste widget*).

In the widget configuration form:

1. Select the widget type.
2. Configure widget parameters.
3. Click *Add* to add the widget to the dashboard.

Editing widgets

Each widget includes controls in its upper-right corner:

-  - edit the widget
-  - open the **widget menu**

After editing, click *Apply* in the widget, then *Save changes* in the upper-right corner of the dashboard to apply your changes.

Copying/pasting widgets

You can copy and paste dashboard widgets to quickly create new widgets with the same configuration. Widgets can be copy-pasted within the same dashboard or between dashboards opened in different tabs.

To copy a widget, use the **widget menu**. To paste a copied widget (available in dashboard **editing mode**):

- Click the arrow next to the *Add* button and select *Paste widget*.
- Alternatively, click an empty area in the dashboard and select *Paste widget*.

You can also paste a copied widget over an existing widget using the *Paste* option in its **widget menu**.

Creating a slideshow

A slideshow will run automatically if the dashboard contains two or more pages (see **Adding pages**) and if one of the following is true:

- The *Start slideshow automatically* option is marked in dashboard properties
- The dashboard URL contains a `slideshow=1` parameter

The pages rotate according to the intervals given in the properties of the dashboard and individual pages. Click on:

- *Stop slideshow* - to stop the slideshow
- *Start slideshow* - to start the slideshow

Slideshow-related controls are also available in **kiosk mode** (where only the page content is shown):

-  - stop slideshow
-  - start slideshow
-  - go back one page
-  - go to the next page

Adding pages

To add a new page to a dashboard:

- Make sure the dashboard is in the **editing mode**
- Click on the arrow next to the *Add* button and select the *Add page* option

- Fill the general page parameters and click on *Apply*. If you leave the name empty, the page will be added with a Page N name where 'N' is the incremental number of the page. The page display period allows to customize how long a page is displayed in a slideshow.

Dashboard page properties

Name

Page display period

Default (30 seconds) ▾

Apply

Cancel

A new page will be added, indicated by a new tab (*Page 2*).

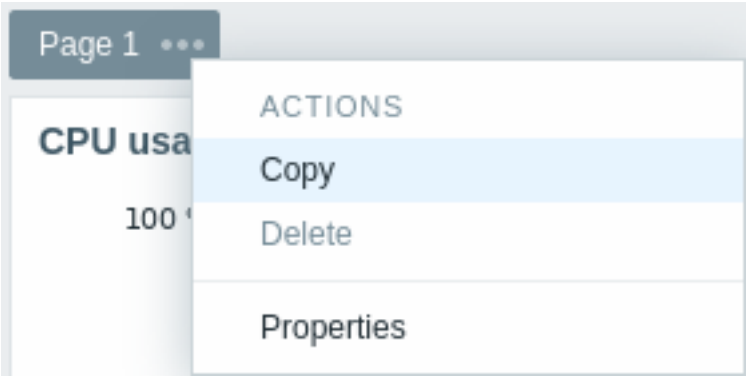

The pages can be reordered by dragging-and-dropping the page tabs. Reordering maintains the original page naming. It is always possible to go to each page by clicking on its tab.

When a new page is added, it is empty. You can add widgets to it as described above.

Copying/pasting pages

Dashboard pages can be copied and pasted, allowing to create a new page with the properties of an existing one. They can be pasted from the same dashboard or a different dashboard.

To paste an existing page to the dashboard, first copy it, using the **page menu**:

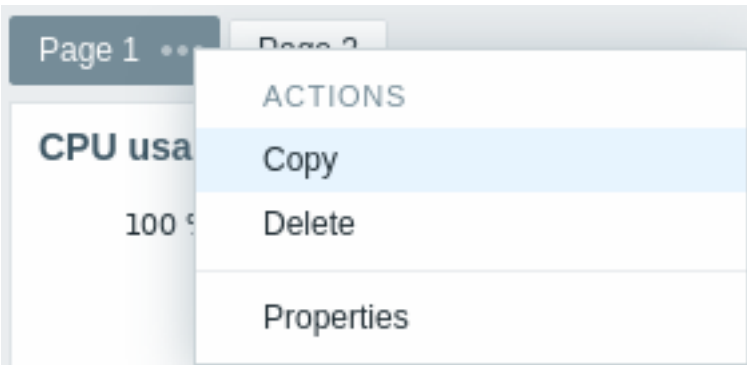

To paste the copied page:

- Make sure the dashboard is in the **editing mode**
- Click on the arrow next to the *Add* button and select the *Paste page* option

Page menu

The page menu can be opened by clicking on the three dots  next to the page name:

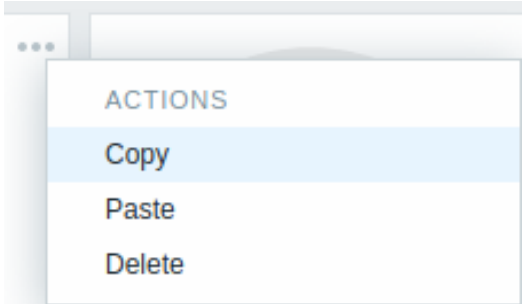

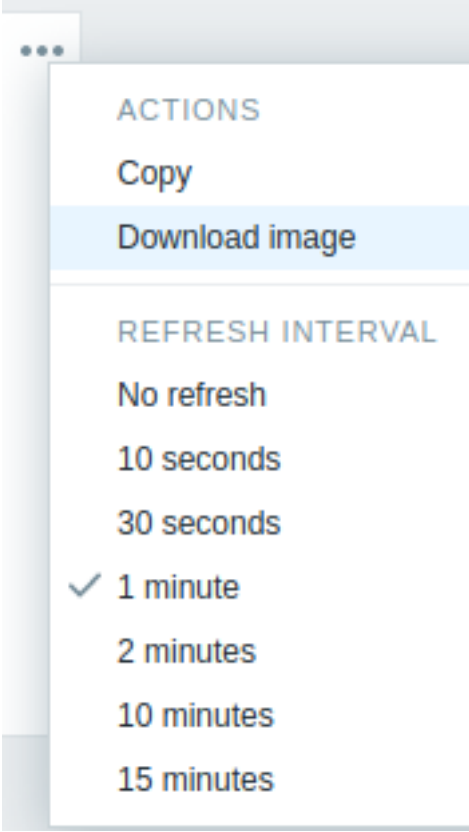

It contains the following options:

- *Copy* - copy the page
- *Delete* - delete the page (pages can only be deleted in the dashboard editing mode)
- *Properties* - customize the page parameters (the name and the page display period in a slideshow)

Widget menu

The widget menu contains different options based on whether the dashboard is in the edit or view mode:

| Widget menu | Options |
|---|--|
| In dashboard edit mode: | |
|  | <i>Copy</i> - copy the widget <i>Paste</i> - paste a copied widget over this widget This option is grayed out if no widget has been copied. <i>Delete</i> - delete the widget |

| Widget menu | Options |
|---|--|
| <p>In dashboard view mode:</p>  | <p><i>Copy</i> - copy the widget</p> <p><i>Download image</i> - download the widget as a PNG image (only available for graph/classic graph widgets)</p> <p><i>Refresh interval</i> - select the frequency of refreshing the widget contents</p> |

Permissions to dashboards

Permissions to dashboards for regular users and users of 'Admin' type (provided the access to dashboards and the *Create and edit dashboards* option are enabled for the **user role** they are assigned) are limited in the way described below.

- They can see and clone a public dashboard even when no users or user groups are added in the dashboard's **sharing preferences**.
- They can see and clone a private dashboard if they have at least *Read* rights to it set by means of the **sharing preferences**.
- They can edit and delete a dashboard only if they have *Read-write* rights to it set by means of the **sharing preferences**.
- They cannot change the dashboard owner.

1 Dashboard widgets

Overview

This section provides the details of parameters that are common for **dashboard** widgets.

Common parameters

The following parameters are common for every single widget:

| | |
|-------------|----------------------|
| <i>Name</i> | Enter a widget name. |
|-------------|----------------------|

| | |
|-------------------------|--|
| <i>Refresh interval</i> | <p>Configure the default refresh interval.</p> <p>Default refresh intervals for widgets range from <i>No refresh</i> to <i>15 minutes</i> depending on the type of the widget. For example:</p> <ul style="list-style-type: none"> - <i>No refresh</i> for <i>URL</i> widget; - <i>1 minute</i> for <i>Action log</i> widget; - <i>15 minutes</i> for <i>Clock</i> widget. <p>Refresh intervals can be set to a default value for all users. Switch the dashboard to editing mode, click the edit a widget button and select the desired refresh interval from the dropdown list.</p> <p>Each user can also set their own widget refresh interval. In dashboard viewing mode, click the three dots  button on a widget and select the desired refresh interval from the dropdown list. Note that a user's unique refresh interval takes priority over the widget setting and is preserved even when the widget's setting is modified.</p> |
| <i>Show header</i> | <p>Mark the checkbox to permanently display the widget header.</p> <p>When unmarked, the header is hidden to save space and becomes visible only on widget mouseover (both in view and edit modes). The header is also semi-visible when dragging a widget to a new place.</p> |

Specific parameters

To see specific parameters for each widget, go to individual widget pages:

- [Action log](#)
- [Clock](#)
- [Discovery status](#)
- [Favorite graphs](#)
- [Favorite maps](#)
- [Gauge](#)
- [Geomap](#)
- [Graph](#)
- [Graph \(classic\)](#)
- [Graph prototype](#)
- [Honeycomb](#)
- [Host availability](#)
- [Host card](#)
- [Host navigator](#)
- [Item history](#)
- [Item navigator](#)
- [Item value](#)
- [Map](#)
- [Map navigation tree](#)
- [Pie chart](#)
- [Problem hosts](#)
- [Problems](#)
- [Problems by severity](#)
- [SLA report](#)
- [System information](#)
- [Top hosts](#)
- [Top items](#)
- [Top triggers](#)
- [Trigger overview](#)
- [URL](#)
- [Web monitoring](#)

Dynamic parameters

Multiple widgets have parameters that enable them to share configuration data between other widgets or the dashboard.

Host groups, Hosts, Item, Item list

The *Host groups*, *Hosts*, *Item*, and *Item list* parameters allow selecting either the respective entities or a data source containing

either host groups, hosts or items for which the widget can display data.

For *Host groups*, *Item*, and *Item list* parameters, the data source can be a compatible widget from the same dashboard.

For *Hosts* parameter, the data source can be a compatible widget from the same dashboard or the dashboard itself.

Note:

The *Map* widget can also broadcast host group and host data to compatible widgets. For more information, see [Widget behavior](#).

Override host

The *Override host* parameter allows selecting a data source containing a host for which the widget can display data. The data source can be a compatible widget from the same dashboard or the dashboard itself.

Override host Select ▼

Add Cancel

Widget
Dashboard

- To specify a [compatible widget](#), enter its name and select it. Alternatively, click the *Select* button (or the dropdown button, then "Widget") to open a pop-up of available widgets.
- To specify a dashboard, click the dropdown button, then "Dashboard". After [saving](#) the dashboard, the *Host* field (for selecting hosts) will appear at the top of the dashboard.

Host Select Edit dashboard ≡ 🔄

Time period

The *Time period* parameter allows selecting a data source containing a time period for which the widget can display data. The data source can be a compatible widget from the same dashboard, the dashboard itself, or the time period configured on the widget itself.

Time period Dashboard Widget Custom

* From 📅

* To 📅

- To specify a [compatible widget](#), set *Time period* to "Widget", enter its name and select it. Alternatively, click the *Select* button to open a pop-up of available widgets.
- To specify a dashboard, set *Time period* to "Dashboard". After [saving](#) the dashboard, the *Time period selector* will appear at the top of the dashboard.
- To configure the time period on the widget itself, set *Time period* to "Custom" and enter or select the start and end of the time period.

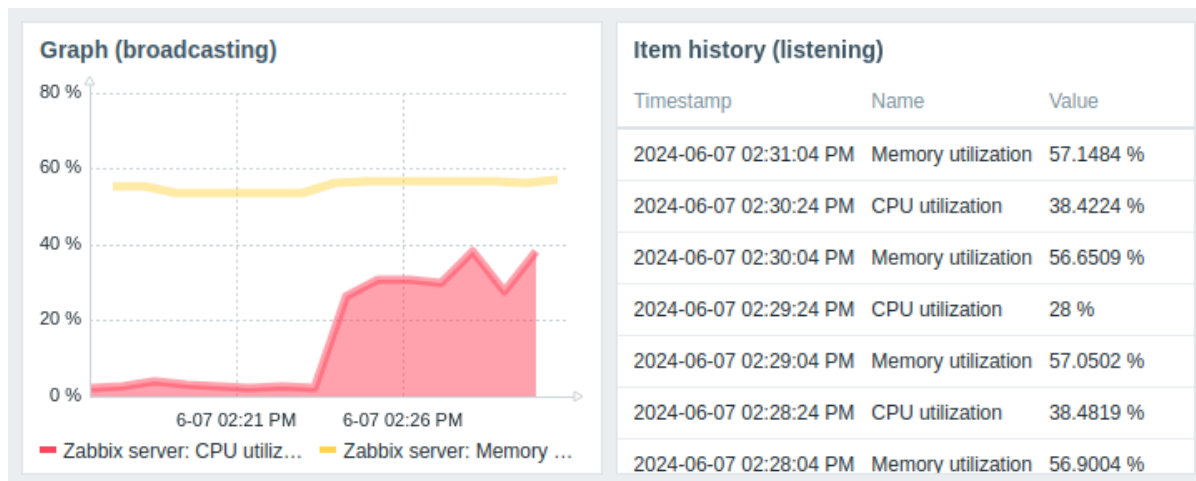

Note:

Regardless of the widget's *Time period* configuration, compatible widgets can use it as a data source for the time period.

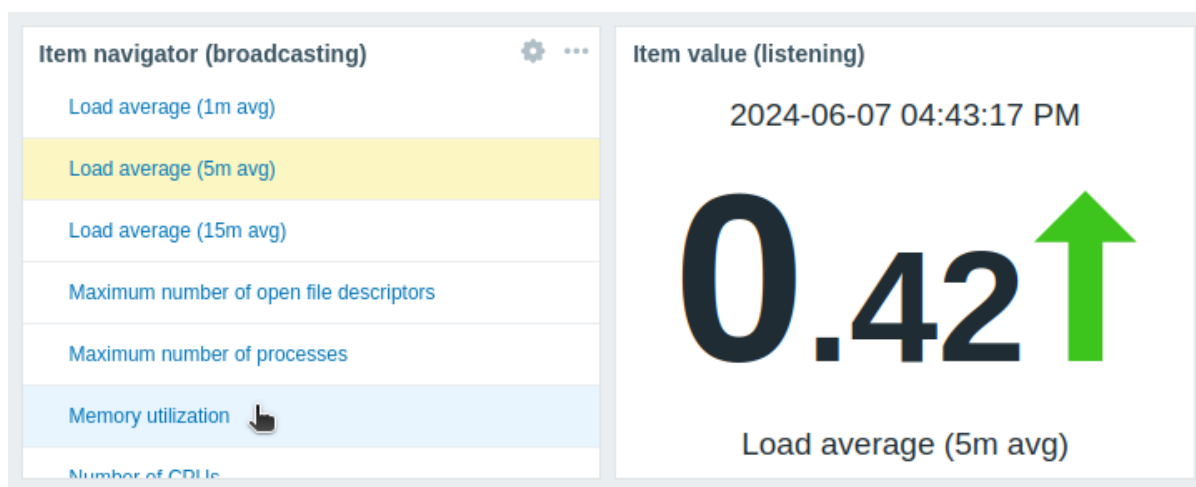

Widget behavior

Widgets differ in how they **broadcast** data to other widgets.

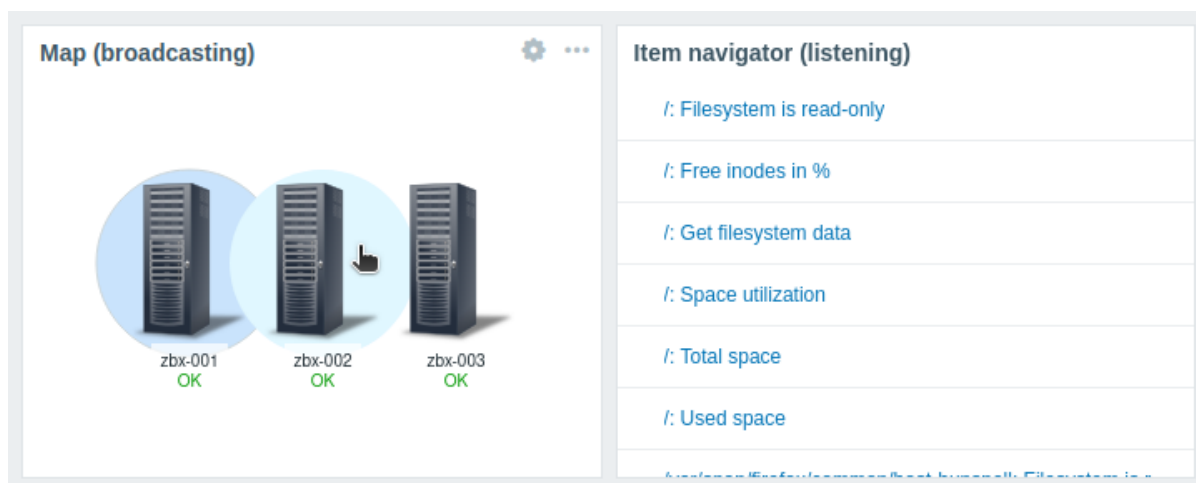

All widgets capable of broadcasting data begin doing so automatically upon creation. For example, the *Graph* widget immediately broadcasts time period data to listening widgets.

Widgets supporting entity selection (e.g., *Item navigator*) automatically broadcast data for the first available entity. For example, the *Item navigator* widget broadcasts data for the first item in its item list. When a different item is selected, it broadcasts data for that item. On mouseover, the item is highlighted in light blue color; on selection, it is highlighted in yellow color.

The *Map* widget also automatically broadcasts data for the first available element (e.g., host), which is closest to the top-left corner of the widget's viewport (for *Geomap* widget, closest to the center of the widget's viewport). When a different element is selected, it broadcasts data for that element. On mouseover, the element is highlighted in light blue color; on selection, it is highlighted in dark blue color.

Widgets also have specific behaviors when **listening** for data from other widgets:

- If the data source widget is not broadcasting data, the listening widget enters the *Awaiting data* state.
- If the data source widget has been deleted, replaced with an incompatible widget, or moved to another dashboard page, the listening widget enters the *Referred widget is unavailable* state.
- If the specified host in the data source (widget or dashboard) lacks the entity configured in the listening widget (item, graph, map, etc.) or if the user lacks permissions to access the host, the listening widget displays the following message: *"No permissions to referred object or it does not exist!"*

For the broadcasting and listening capabilities of each widget, see [Widget compatibility](#).

Widget compatibility

Some widgets can broadcast configuration data to other widgets, some can listen for data, and some can do both. For example:

- The *Action log* widget can only retrieve time period data from *Graph*, *Graph (classic)*, and *Graph prototype* widgets.
- The *Geomap* widget can broadcast host data to widgets that listen for it (*Honeycomb*, *Top items*, etc.) and can also listen for host group and host data from widgets that broadcast it (*Honeycomb*, *Problem hosts*, etc.).
- The *Clock* widget cannot broadcast or listen for any data.

The following table outlines the broadcasting and listening capabilities of each widget.

| Widget | Broadcasts | Listens |
|-----------------------------|--------------------|-----------------------------------|
| <i>Action log</i> | - | Time period |
| <i>Clock</i> | - | - |
| <i>Discovery status</i> | - | - |
| <i>Favorite graphs</i> | - | - |
| <i>Favorite maps</i> | - | - |
| <i>Gauge</i> | - | Hosts, Items |
| <i>Geomap</i> | Hosts | Host groups, Hosts |
| <i>Graph</i> | Time period | Time period, Items, Hosts |
| <i>Graph (classic)</i> | Time period | Hosts, Items, Graphs, Time period |
| <i>Graph prototype</i> | Time period | Hosts, Time period |
| <i>Honeycomb</i> | Hosts, Items | Host groups, Hosts |
| <i>Host availability</i> | - | Host groups |
| <i>Host card</i> | - | Hosts |
| <i>Host navigator</i> | Hosts | Host groups |
| <i>Item history</i> | Items | Hosts, Time period |
| <i>Item navigator</i> | Items | Host groups, Hosts |
| <i>Item value</i> | - | Hosts, Items, Time period |
| <i>Map</i> | Host groups, Hosts | Maps |
| <i>Map navigation tree</i> | Maps | - |
| <i>Pie chart</i> | - | Time period, Items |
| <i>Problem hosts</i> | Host groups | Host groups, Hosts |
| <i>Problems</i> | Events | Host groups, Hosts |
| <i>Problems by severity</i> | Host groups | Host groups, Hosts |
| <i>SLA report</i> | - | - |
| <i>System information</i> | - | - |
| <i>Top hosts</i> | Hosts | Host groups, Hosts |
| <i>Top items</i> | - | Host groups, Hosts |
| <i>Top triggers</i> | - | Time period |

| Widget | Broadcasts | Listens |
|------------------|-------------|--------------------|
| Trigger overview | - | Host groups, Hosts |
| URL | - | Hosts |
| Web monitoring | Host groups | Host groups, Hosts |

1 Action log

Overview

In the action log widget, you can display details of action operations (notifications, remote commands). It replicates information from *Reports* → *Action log*.

Up to 1000 records can be displayed.

Configuration

To configure, select *Action log* as type:

Add widget

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|--------------------|---|
| <i>Recipients</i> | Filter entries by recipients. This field is auto-complete, so starting to type the name of a recipient will offer a dropdown of matching recipients. If no recipients are selected, details of action operations for all recipients will be displayed. |
| <i>Actions</i> | Filter entries by actions. This field is auto-complete, so starting to type the name of an action will offer a dropdown of matching actions. If no actions are selected, details of action operations for all actions will be displayed. |
| <i>Media types</i> | Filter entries by media types. This field is auto-complete, so starting to type the name of a media type will offer a dropdown of matching media types. If no media types are selected, details of action operations for all media types will be displayed. |

| | |
|------------------------|---|
| <i>Status</i> | <p>Mark the checkbox to filter entries by the respective status:</p> <p>In progress - action operations that are in progress are displayed;</p> <p>Sent/Executed - action operations that have sent a notification or have been executed are displayed;</p> <p>Failed - action operations that have failed are displayed.</p> |
| <i>Search string</i> | <p>Filter entries by the content of the message/remote command. If you enter a string here, only those action operations whose message/remote command contains the entered string will be displayed. Macros are not resolved.</p> |
| <i>Time period</i> | <p>Filter entries by time period. Select the data source for the time period:</p> <p>Dashboard - set the <i>Time period</i> selector as the data source;</p> <p>Widget - set a compatible widget specified in the <i>Widget</i> parameter as the data source;</p> <p>Custom - set the time period specified in the <i>From</i> and <i>To</i> parameters as the data source; if set, a clock icon will be displayed in the top right corner of the widget, indicating the set time on mouseover.</p> |
| <i>Widget</i> | <p>Enter or select a compatible widget as the data source for the time period.</p> <p>This parameter is available if <i>Time period</i> is set to "Widget".</p> |
| <i>From</i> | <p>Enter or select the start of the time period.</p> <p>Relative time syntax (<code>now</code>, <code>now/d</code>, <code>now/w-1w</code>, etc.) is supported.</p> <p>This parameter is available if <i>Time period</i> is set to "Custom".</p> |
| <i>To</i> | <p>Enter or select the end of the time period.</p> <p>Relative time syntax (<code>now</code>, <code>now/d</code>, <code>now/w-1w</code>, etc.) is supported.</p> <p>This parameter is available if <i>Time period</i> is set to "Custom".</p> |
| <i>Sort entries by</i> | <p>Sort entries by:</p> <p>Time (descending or ascending);</p> <p>Type (descending or ascending);</p> <p>Status (descending or ascending);</p> <p>Recipient (descending or ascending).</p> |
| <i>Show lines</i> | <p>Set how many action log lines will be displayed in the widget.</p> |

2 Clock

Overview

In the clock widget, you may display local, server, or specified host time.

Both analog and digital clocks can be displayed:

Configuration

To configure, select *Clock* as type:

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|-------------------------------|---|
| <i>Time type</i> | Select local, server, or specified host time. Server time will be identical to the time zone set globally or for the Zabbix user. |
| <i>Item</i> | Select the item for displaying time. To display host time, use the <code>system.localtime[local]</code> item . This item must exist on the host. This field is available only when <i>Host time</i> is selected. |
| <i>Clock type</i> | Select clock type: Analog - analog clock Digital - digital clock |
| <i>Show</i> | Select information units (date, time, time zone) to display in the digital clock. Unit size is dynamic, filling all available widget space based on displayed units, widget size, and display scaling. This field is available only if "Digital" is selected in the <i>Clock type</i> field; at least one information unit type must be selected. |
| <i>Advanced configuration</i> | Click on the <i>Advanced configuration</i> label to display advanced configuration options for the digital clock. This section is available only if "Digital" is selected in the <i>Clock type</i> field. |

Advanced configuration

Advanced configuration options are available in the collapsible *Advanced configuration* section, and only for those elements that are selected in the *Show* field (see above).

Additionally, advanced configuration allows to change the background color for the whole widget.

Advanced configuration

| | | |
|------------------|---|---|
| Background color | <div>D</div> | |
| Date | Bold <input type="checkbox"/> | Color <div>D</div> |
| Time | Bold <input type="checkbox"/> | Color <div>D</div> |
| | Seconds <input checked="" type="checkbox"/> | Format <div>24-hour 12-hour</div> |
| Time zone | Bold <input type="checkbox"/> | Color <div>D</div> |
| | Time zone | <div>Local default: (UTC+03:00) Europe/Riga</div> |
| | Format | <div>Short Full</div> |

Background color

Select the background color from the color picker.
D stands for default color (depends on the frontend theme). To return to the default value, click the *Use default* button in the color picker.

Date

Bold

Mark the checkbox to display date in bold type.

Color

Select the date color from the color picker.
D stands for default color (depends on the frontend theme). To return to the default value, click the *Use default* button in the color picker.

Time

Bold

Mark the checkbox to display time in bold type.

Color

Select the time color from the color picker.
D stands for default color (depends on the frontend theme). To return to the default value, click the *Use default* button in the color picker.

Seconds

Mark the checkbox to display seconds. Otherwise only hours and minutes will be displayed.

Format

Select to display a 24-hour or 12-hour time.

Time zone

Bold

Mark the checkbox to display time zone in bold type.

Color

Select the time zone color from the color picker.
D stands for default color (depends on the frontend theme). To return to the default value, click the *Use default* button in the color picker.

Time zone

Select the time zone.

Format

Select to display time zone in short format (e.g. New York) or full format (e.g. (UTC-04:00) America/New York).

3 Discovery status

Overview

This widget displays a status summary of the active network discovery rules.

Add widget ? ×

| | | |
|------------------|-------------------------------|---|
| Type | <div>Discovery status</div> | Show header <input checked="" type="checkbox"/> |

| Refresh interval | <div>Default (1 minute)</div> | |

Add

Cancel

All configuration parameters are **common** for all widgets.

4 Favorite graphs

Overview

This widget contains shortcuts to the most needed graphs, sorted alphabetically.

The list of shortcuts is populated when you view a graph in Monitoring -> Latest data -> Graphs, and then click on its  *Add to favorites* button.

All configuration parameters are **common** for all widgets.

5 Favorite maps

Overview

This widget contains shortcuts to the most needed maps, sorted alphabetically.

The list of shortcuts is populated when you **view** a map and then click on its  *Add to favorites* button.

All configuration parameters are **common** for all widgets.

6 Gauge

Overview

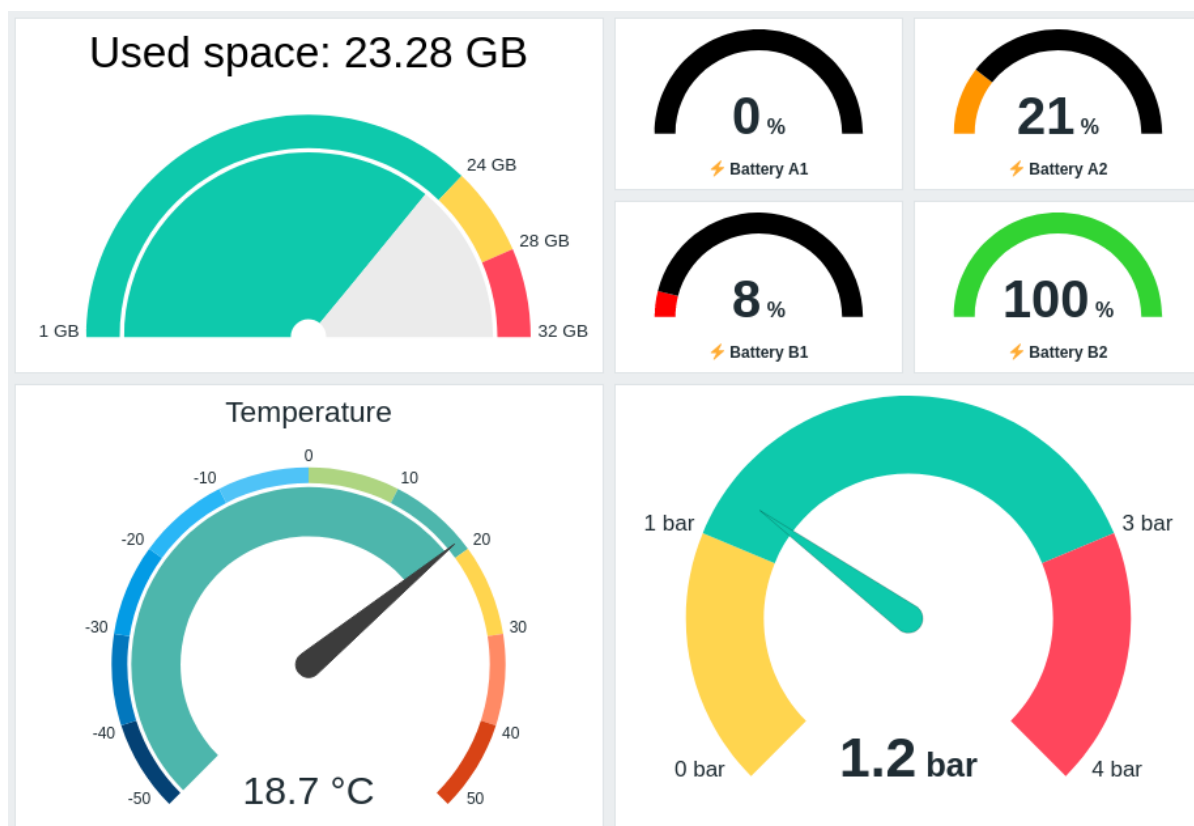

The gauge widget displays the value of a single item as a gauge.

When configured, the widget can consist of the following elements:

- Item description (for example, "CPU utilization", "Speed")
- Item value (for example, "30.70", "19.80")
- Item value units (for example, "%", "km/h")
- Gauge scale (for example, "0%/100%", "0/100/180/200")
- Gauge arc (gauge value arc and gauge thresholds arc)
- Gauge needle

The widget can be visually fine-tuned using the **advanced configuration** options to create a wide variety of visual styles:

The gauge widget can display only numeric values. Displaying binary values is not supported.

Clicking on the gauge widget leads to a graph for the item.

Configuration

To configure, select *Gauge* as type:

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|-------------------------------|---|
| <i>Item</i> | <p>Select the item.</p> <p>Alternatively, select a compatible widget as the data source for items.</p> <p>This field is auto-complete, so starting to type the name of an item will offer a dropdown of matching items.</p> <p>Note that you can select only items that return numeric data.</p> |
| <i>Min</i> | <p>Enter the minimum value of the gauge.</p> <p>Suffixes (for example, "1d", "2w", "4K", "8G") are supported. Value mappings are supported.</p> |
| <i>Max</i> | <p>Enter the maximum value of the gauge.</p> <p>Suffixes (for example, "1d", "2w", "4K", "8G") are supported. Value mappings are supported.</p> |
| <i>Colors</i> | <p>Select the color from the color picker:</p> <p>Value arc - select the gauge value arc color;</p> <p>Arc background - select the gauge value arc and gauge thresholds arc background color;</p> <p>Background - select the widget background color.</p> <p>"D" stands for the default color, which depends on the frontend theme. If Thresholds are set, the default color for Value arc depends on the threshold color. To return to the default color, click the <i>Use default</i> button in the color picker.</p> |
| <i>Show</i> | <p>Mark the checkbox to display the respective gauge element - description, value, value arc, needle, scale (the minimum and maximum value of the gauge at the beginning and end of the gauge arc). Unmark to hide. At least one element must be selected.</p> <p>Note that the gauge needle and scale can be displayed if the gauge value arc or gauge thresholds arc (see advanced configuration options) is displayed. Also note that if the gauge needle is displayed, the value is placed under the needle; if the needle is hidden, the value is aligned with the bottom of the gauge arc.</p> |
| <i>Override host</i> | <p>Select a compatible widget or the dashboard as the data source for hosts.</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |
| <i>Advanced configuration</i> | <p>Click the <i>Advanced configuration</i> label to display advanced configuration options. This is also where you'll be able to adjust the gauge elements selected in the <i>Show</i> field.</p> |

Advanced configuration

Advanced configuration options are available in the collapsible *Advanced configuration* section:

Angle

Select the gauge angle (180° or 270°).

Description

Description

Enter the item description. This description may override the default item name. Multiline descriptions are supported. A combination of text and supported macros is possible. {HOST.*}, {ITEM.*}, {INVENTORY.*} and user macros are supported.

Size

Vertical position

Bold

Color

Enter the font size height for the item description (in percent, relative to the total widget height).

Select the vertical position of the item description (top or bottom, relative to the gauge arc).

Mark the checkbox to display the item description in bold.

Select the item description color from the color picker.

"D" stands for the default color, which depends on the frontend theme. To return to the default color, click the *Use default* button in the color picker.

Value

Decimal places

Enter the number of decimal places to display with the value.

This option affects only items that return **numeric (float)** data.

Size

Bold

Color

Enter the font size height for the value (in percent, relative to the gauge arc height).

Mark the checkbox to display the value in bold.

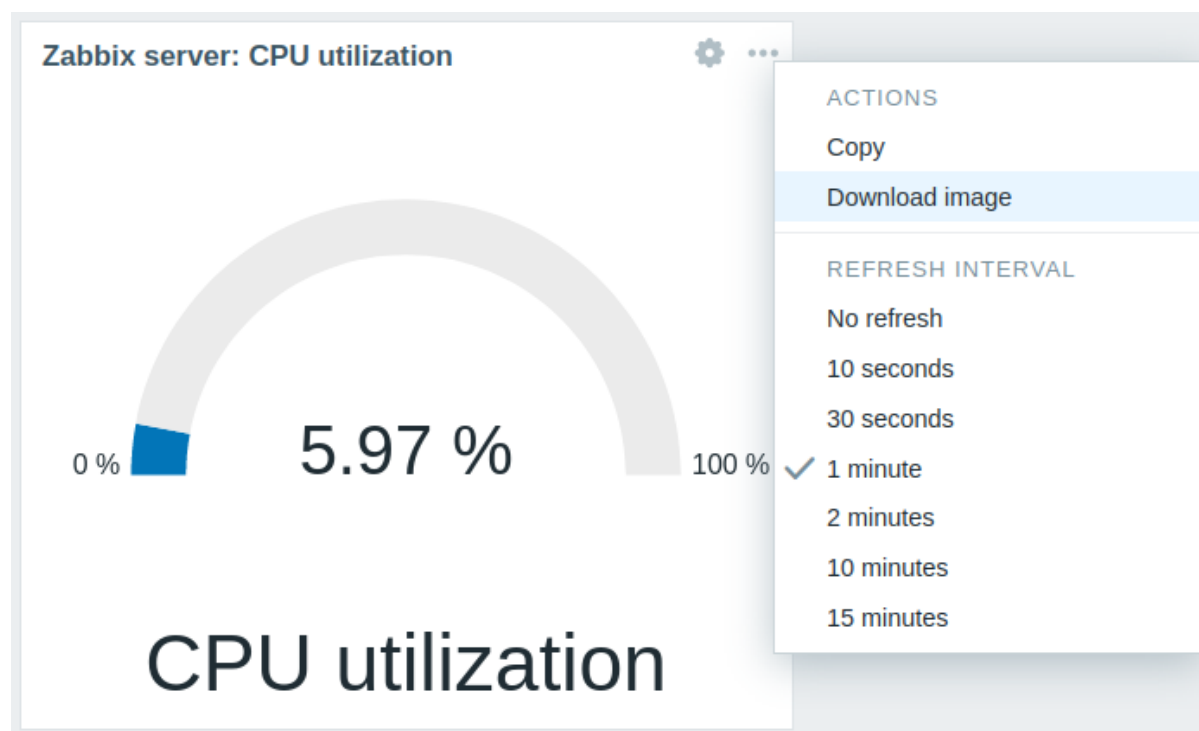

Select the value color from the color picker.

"D" stands for the default color, which depends on the frontend theme. To return to the default color, click the *Use default* button in the color picker.

Units

| | |
|-----------------------|--|
| <i>Units</i> | Mark the checkbox to display units with the item value. If you enter a unit name, it will override the units set in the item configuration . |
| <i>Size</i> | Enter the font size height for the item units (in percent, relative to the gauge arc height). |
| <i>Bold</i> | Mark the checkbox to display item units in bold. |
| <i>Position</i> | Select the position of the item units (above, below, before or after, relative to the item value). This option is ignored for the following time-related units : unixtime, uptime, s. |
| <i>Color</i> | Select the item units color from the color picker. "D" stands for the default color, which depends on the frontend theme. To return to the default color, click the <i>Use default</i> button in the color picker. |
| Value arc | |
| <i>Arc size</i> | Enter the size height of the gauge value arc (in percent, relative to the gauge arc radius). |
| Needle | |
| <i>Color</i> | Select the gauge needle color from the color picker. "D" stands for the default color, which depends on the frontend theme. If <i>Thresholds</i> are set, the default color for the needle depends on the threshold color. To return to the default color, click the <i>Use default</i> button in the color picker. |
| Scale | |
| <i>Show units</i> | Mark the checkbox to display units with the minimum and maximum value of the gauge. |
| <i>Size</i> | Enter the font size height for the minimum and maximum value of the gauge (in percent, relative to the gauge arc height). |
| <i>Decimal places</i> | Enter the number of decimal places to display with the minimum and maximum value of the gauge. This option affects only items that return numeric (float) data. |
| Thresholds | |
| <i>Thresholds</i> | Click <i>Add</i> to add a threshold, select a threshold color from the color picker, and specify a numeric value. The thresholds list will be sorted in ascending order when saved. Note that the colors configured as thresholds will be displayed correctly only for numeric items. Suffixes (for example, "1d", "2w", "4K", "8G") are supported. Value mappings are supported. |
| <i>Show labels</i> | Mark the checkbox to display threshold values as labels on the gauge scale. |
| <i>Show arc</i> | Mark the checkbox to display the gauge thresholds arc. |
| <i>Arc size</i> | Enter the size height of the gauge thresholds arc (in percent, relative to the gauge arc radius). |

The information displayed by the gauge widget can be downloaded as a *.png* image using the **widget menu**:

A screenshot of the widget will be saved to the *Downloads* folder.

Overview

Geomap widget displays hosts as markers on a geographical map using open-source JavaScript interactive maps library Leaflet.

Note:

Zabbix offers multiple predefined map tile service providers and an option to add a custom tile service provider or even host tiles themselves (configurable in the *Administration* → *General* → *Geographical maps* [menu section](#)).

By default, the widget displays all enabled hosts with valid geographical coordinates defined in the host configuration. It is possible to configure host filtering in the widget parameters.

The valid host coordinates are:

- Latitude: from -90 to 90 (can be integer or float number)
- Longitude: from -180 to 180 (can be integer or float number)

Configuration

To add the widget, select *Geomap* as type.

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|-------------|--|
| Host groups | <p>Select host groups to be displayed on the map.</p> <p>Alternatively, select a compatible widget as the data source for host groups.</p> <p>This field is auto-complete, so starting to type the name of a group will offer a dropdown of matching groups.</p> <p>If nothing is selected in both <i>Host groups</i> and <i>Hosts</i> fields, all hosts with valid coordinates will be displayed.</p> |
| Hosts | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Select hosts to be displayed on the map.</p> <p>Alternatively, select a compatible widget or the dashboard as the data source for hosts.</p> <p>This field is auto-complete, so starting to type the name of a host will offer a dropdown of matching hosts.</p> <p>If nothing is selected in both <i>Host groups</i> and <i>Hosts</i> fields, all hosts with valid coordinates will be displayed.</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |

Tags

Specify tags to limit the number of hosts displayed in the widget.
It is possible to include as well as exclude specific tags and tag values. Several conditions can be set. Tag name matching is always case-sensitive.

There are several operators available for each condition:

Exists - include the specified tag names;

Equals - include the specified tag names and values (case-sensitive);

Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive);

Does not exist - exclude the specified tag names;

Does not equal - exclude the specified tag names and values (case-sensitive);

Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).

There are two calculation types for conditions:

And/Or - all conditions must be met, conditions having the same tag name will be grouped by the *Or* condition;

Or - enough if one condition is met.

Initial view

This parameter is not available when configuring the widget on a **template dashboard**.

Comma-separated center coordinates and an optional zoom level to display when the widget is initially loaded in the format <latitude>,<longitude>,<zoom>

If initial zoom is specified, the Geomap widget is loaded at the given zoom level. Otherwise, initial zoom is calculated as half of the **max zoom** for the particular tile provider.

The initial view is ignored if the default view is set (see below).

Examples:

40.6892494,-74.0466891,14

40.6892494,-122.0466891

Host markers displayed on the map have the color of the host's most serious problem and green color if a host has no problems. Clicking on a host marker allows viewing the host's visible name and the number of unresolved problems grouped by severity. Clicking on the visible name will open **host menu**.

Hosts displayed on the map can be filtered by problem severity. Press on the filter icon in the widget's upper right corner and mark the required severities.

It is possible to zoom in and out the map by using the plus and minus buttons in the widget's upper left corner or by using the mouse scroll wheel or touchpad. To set the current view as default, right-click anywhere on the map and select *Set this view as default*. This setting will override *Initial view* widget parameter for the current user. To undo this action, right-click anywhere on the map again and select *Reset to initial view*.

When *Initial view* or *Default view* is set, you can return to this view at any time by pressing on the home icon on the left.

8 Graph

Overview

The graph widget provides a modern and versatile way of visualizing data collected by Zabbix using a vector image drawing technique. This graph widget is supported since Zabbix 4.0. Note that the graph widget supported before Zabbix 4.0 can still be used as [Graph \(classic\)](#). See also [Adding widgets](#) section on *Dashboards* page for more details.

Configuration

To configure, select *Graph* as type:

Data set

The **Data set** tab allows selecting data for the graph by adding data sets. Two types of data sets can be added:

- *Item patterns* - data from matching items is displayed. The graph is drawn using different shades of single color for each item.
- *Item list* - data from selected items is displayed. The graph is drawn using different colors for each item.

By default, an *Item patterns* data set is added.

| | |
|-----------------------------|--|
| <i>Data set</i> | <p>For Item patterns data set:</p> <p>Select or enter host and item patterns; data of items that match these patterns will be displayed on the graph; up to 50 items may be displayed.</p> <p>Wildcard patterns may be used for selection (for example, * will return results that match zero or more characters).</p> <p>To specify a wildcard pattern, enter the string manually and press <i>Enter</i>.</p> <p>The wildcard symbol is always interpreted, so it is not possible to add, for example, an item named <i>item*</i> individually if there are other matching items (for example, <i>item2</i>, <i>item3</i>).</p> <p>Specifying host and item patterns is mandatory for "Item patterns" data sets.</p> <p>See also: Data set configuration details.</p> <p>For Item list data set:</p> <p>Select items for the graph by clicking on the <i>Add item</i> button.</p> <p>You may also select compatible widgets as the data source for items by clicking on the <i>Add widget</i> button.</p> <p>Specifying items or widgets is mandatory for "Item list" data sets.</p> <p>See also: Data set configuration details.</p> <p>Note that only numeric item types are allowed.</p> <p>When configuring the widget on a template dashboard, the parameter for specifying host patterns is not available, and the parameter for specifying an item list allows to select only the items configured on the template.</p> |
| <i>Draw</i> | <p>Choose the draw type of the metric.</p> <p>Possible draw types: <i>Line</i> (set by default), <i>Points</i>, <i>Staircase</i>, and <i>Bar</i>.</p> <p>Note that if there is only one data point in the line/staircase graph, it is drawn as a point regardless of the draw type. The point size is calculated from the line width, but it cannot be smaller than 3 pixels, even if the line width is less.</p> |
| <i>Stacked</i> | <p>Mark the checkbox to display data as stacked (filled areas displayed).</p> <p>This option is disabled when <i>Points</i> draw type is selected.</p> |
| <i>Width</i> | <p>Set the line width.</p> <p>This option is available when <i>Line</i> or <i>Staircase</i> draw type is selected.</p> |
| <i>Point size</i> | <p>Set the point size.</p> <p>This option is available when <i>Points</i> draw type is selected.</p> |
| <i>Transparency</i> | Set the transparency level. |
| <i>Fill</i> | <p>Set the fill level.</p> <p>This option is available when <i>Line</i> or <i>Staircase</i> draw type is selected.</p> |
| <i>Missing data</i> | <p>Select the option for displaying missing data:</p> <p>None - the gap is left empty;</p> <p>Connected - two border values are connected;</p> <p>Treat as 0 - the missing data is displayed as 0 values;</p> <p>Last known - the missing data is displayed with the same value as the last known value; not applicable for the <i>Points</i> and <i>Bar</i> draw type.</p> |
| <i>Override host</i> | <p>Select a compatible widget or the dashboard as the data source for hosts.</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |
| <i>Y-axis</i> | Select the side of the graph where the Y-axis will be displayed. |
| <i>Time shift</i> | <p>Specify time shift if required.</p> <p>You may use time suffixes in this field. Negative values are allowed.</p> |
| <i>Aggregation function</i> | <p>Specify which aggregation function to use:</p> <p>min - display the smallest value;</p> <p>max - display the largest value;</p> <p>avg - display the average value;</p> <p>sum - display the sum of values;</p> <p>count - display the count of values;</p> <p>first - display the first value;</p> <p>last - display the last value;</p> <p>none - display all values (no aggregation).</p> <p>Aggregation allows to display an aggregated value for the chosen interval (5 minutes, an hour, a day), instead of all values. See also: Aggregation in graphs.</p> |

| | |
|-----------------------------|--|
| <i>Aggregation interval</i> | <p>Specify the interval for aggregating values.</p> <p>You may use time suffixes in this field. A numeric value without a suffix will be regarded as seconds.</p> <p>Note that if the widget is configured to display historical data based on trends (<i>History data selection</i> is set to <i>Trends</i> or <i>Auto</i>), it is recommended to use an aggregation interval that is a multiple of 1 hour (e.g., 3600, 60m, 1h, 3h, etc.). Trends store hourly aggregated values, so using an aggregation interval that is not a multiple of 1 hour (e.g., 100s, 7min, 15min, 90min, etc.) may lead to results that are hard to interpret.</p> |
| <i>Aggregate</i> | <p>Specify whether to aggregate:</p> <p>Each item - each item in the dataset will be aggregated and displayed separately;</p> <p>Data set - all dataset items will be aggregated and displayed as one value.</p> |
| <i>Approximation</i> | <p>Specify what value to display when more than one value exists per vertical graph pixel:</p> <p>all - display the smallest, the largest and the average values;</p> <p>min - display the smallest value;</p> <p>max - display the largest value;</p> <p>avg - display the average value.</p> |
| <i>Data set label</i> | <p>This setting is useful when displaying a graph for a large time period with frequent update interval (such as one year of values collected every 10 minutes).</p> <p>Specify the data set label that is displayed in graph <i>Data set</i> configuration and in graph <i>Legend</i> (for aggregated data sets).</p> <p>All data sets are numbered including those with a specified <i>Data set label</i>. If no label is specified, the data set will be labeled automatically according to its number (e.g. "Data set #2", "Data set #3", etc.). Data set numbering is recalculated after reordering/dragging data sets.</p> <p>Data set labels that are too long will be shortened to fit where displayed (e.g. "Number of proc...").</p> |

Data set configuration details

Existing data sets are displayed in a list. You may:

- Click on the  move icon and drag a data set to a new place in the list.
- Click on the  expand icon to expand data set details. When expanded, this icon turns into a  collapse icon.
- Click on the  color icon to change the color, either from the color picker or manually. For *Item patterns* data set, the color is used to calculate different color shades for each item. For *Item list* data set, the color is used for the specified item.
- Click on the *Add new data set* button to add an empty data set allowing to select host and item patterns. If you click on the downward pointing icon next to the *Add new data set* button, a drop-down menu appears, allowing you to add a new *Item patterns* or *Item list* data set or allowing you to *Clone* the currently open data set. If all data sets are collapsed, the *Clone* option is not available.

The **Item patterns** data set contains *Host patterns* and *Item patterns* fields that both recognize full names or patterns containing a wildcard symbol (*). This functionality allows you to select all the host names and item names containing the selected pattern. While typing the item name or item pattern in the *Item patterns* field, only items belonging to the selected host name(s) are displayed in the dropdown list.

For example, having typed a pattern **z*** in the *Host patterns* field, the dropdown list displays all host names containing this pattern: **z***, **Zabbix server**, **Zabbix proxy**. After pressing *Enter*, this pattern is accepted and is displayed as **z***. Similarly, having typed the pattern **a*** in the *Item patterns* field, the dropdown list displays all item names containing this pattern: **a***, **Available memory**, **Available memory in %**.

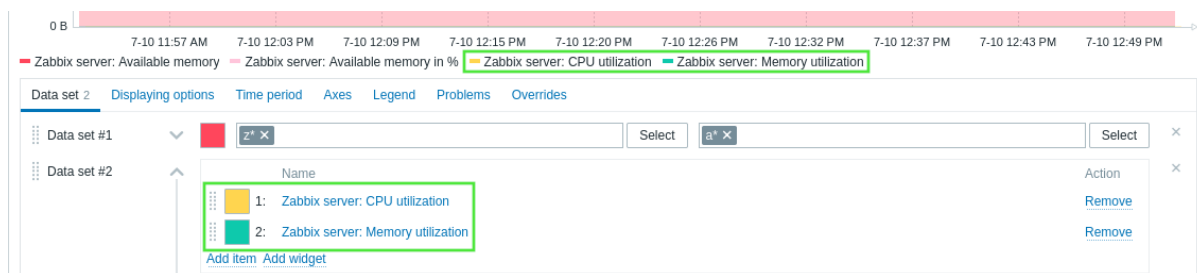

After pressing *Enter*, this pattern is accepted, is displayed as **a***, and all items belonging to the selected host name(s) are displayed in the graph.

The **Item list** data set contains the *Add item* button that allows you to add items to be displayed on the graph. You can also add compatible widgets as the **data source** for items by clicking the *Add widget* button.

For example, clicking the *Add item* button opens a pop-up window containing a *Host* parameter. Having selected a host, all its items that are available for selection are displayed in a list. After selecting one or more items, they will be displayed in the data set item list and in the graph.

Displaying options

The **Displaying options** tab allows to define history data selection:

| Data set 2 | Displaying options | Time period | Axes | Legend | Problems | Overrides |
|---|--------------------|-------------|------|--------|----------|-----------|
| History data selection <input checked="" type="radio"/> Auto <input type="radio"/> History <input type="radio"/> Trends | | | | | | |
| Simple triggers <input type="checkbox"/> | | | | | | |
| Working time <input type="checkbox"/> | | | | | | |
| Percentile line (left) <input type="checkbox"/> value | | | | | | |
| Percentile line (right) <input type="checkbox"/> value | | | | | | |

History data selection

Set the source of graph data:

Auto - data are sourced according to the classic graph **algorithm** (default);

History - data from history;

Trends - data from trends.

| | |
|-------------------------|--|
| Simple triggers | <p>Mark the checkbox to show the trigger thresholds for simple triggers. The thresholds will be drawn as dashed lines using the trigger severity color.</p> <p>A simple trigger is a trigger with one function (only <code>last</code>, <code>max</code>, <code>min</code>, <code>avg</code>) for one item in the expression.</p> <p>A maximum of three triggers can be drawn. Note that the trigger has to be within the drawn range to be visible.</p> |
| Working time | <p>Mark the checkbox to show working time on the graph. Working time (working days) is displayed in graphs as a white background, while non-working time is displayed in gray (with the <i>Original blue</i> default frontend theme).</p> |
| Percentile line (left) | <p>Mark the checkbox and enter the percentile value to show the specified percentile as a line on the left Y-axis of the graph.</p> <p>If, for example, a 95% percentile is set, then the percentile line will be at the level where 95 percent of the values fall under.</p> |
| Percentile line (right) | <p>Mark the checkbox and enter the percentile value to show the specified percentile as a line on the right Y-axis of the graph.</p> <p>If, for example, a 95% percentile is set, then the percentile line will be at the level where 95 percent of the values fall under.</p> |

Time period

The **Time period** tab allows to set a time period for which to display data in the graph:

Data set 2

Displaying options

| | |
|----------------|--|
| <i>Left Y</i> | Mark this checkbox to make left Y-axis visible. The checkbox may be disabled if unselected either in <i>Data set</i> or in <i>Overrides</i> tab. |
| <i>Right Y</i> | Mark this checkbox to make right Y-axis visible. The checkbox may be disabled if unselected either in <i>Data set</i> or in <i>Overrides</i> tab. |
| <i>X-Axis</i> | Unmark this checkbox to hide X-axis (marked by default). |
| <i>Scale</i> | Choose the scale for the graph axis values from the dropdown: Linear - axis values increase by a fixed amount (e.g., 10, 20, 30), suitable for data that changes steadily or covers a small to moderate range; Logarithmic - axis values increase exponentially (e.g., 10, 100, 1000), suitable for data that changes rapidly or covers a large range. |
| <i>Min</i> | Set the minimum value of the corresponding axis. Visible range minimum value of Y-axis is specified. |
| <i>Max</i> | Set the maximum value of the corresponding axis. Visible range maximum value of Y-axis is specified. |
| <i>Units</i> | Choose the unit for the graph axis values from the dropdown: Auto - axis values are displayed using the unit of the first item in the data set; Static - axis values are displayed using the unit specified in the <i>value</i> input field; if the field is left blank, only numeric values are displayed. |

Legend

The **Legend** tab allows to customize the graph legend:

|---------------------|---|
| Show problems | Mark this checkbox to enable problem displaying on the graph (unmarked, i.e., disabled by default). |
| Selected items only | Mark this checkbox to include problems for the selected items only to be displayed on the graph. |
| Problem hosts | <p>Select the problem hosts to be displayed on the graph.</p> <p>Wildcard patterns may be used (for example, * will return results that match zero or more characters).</p> <p>To specify a wildcard pattern, just enter the string manually and press <i>Enter</i>.</p> <p>While you are typing, note how all matching hosts are displayed in the dropdown.</p> |
| Severity | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Mark problem severities to filter problems to be displayed on the graph.</p> <p>If no severities are marked, all problems will be displayed.</p> |
| Problem | Specify the problem's name to be displayed on the graph. |
| Problem tags | <p>Specify problem tags to limit the number of problems displayed in the widget.</p> <p>It is possible to include as well as exclude specific tags and tag values. Several conditions can be set. Tag name matching is always case-sensitive.</p> <p>There are several operators available for each condition:</p> <p>Exists - include the specified tag names;</p> <p>Equals - include the specified tag names and values (case-sensitive);</p> <p>Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive);</p> <p>Does not exist - exclude the specified tag names;</p> <p>Does not equal - exclude the specified tag names and values (case-sensitive);</p> <p>Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).</p> <p>There are two calculation types for conditions:</p> <p>And/Or - all conditions must be met, conditions having the same tag name will be grouped by the <i>Or</i> condition;</p> <p>Or - enough if one condition is met.</p> |

Overrides

The **Overrides** tab allows to add custom overrides for data sets:

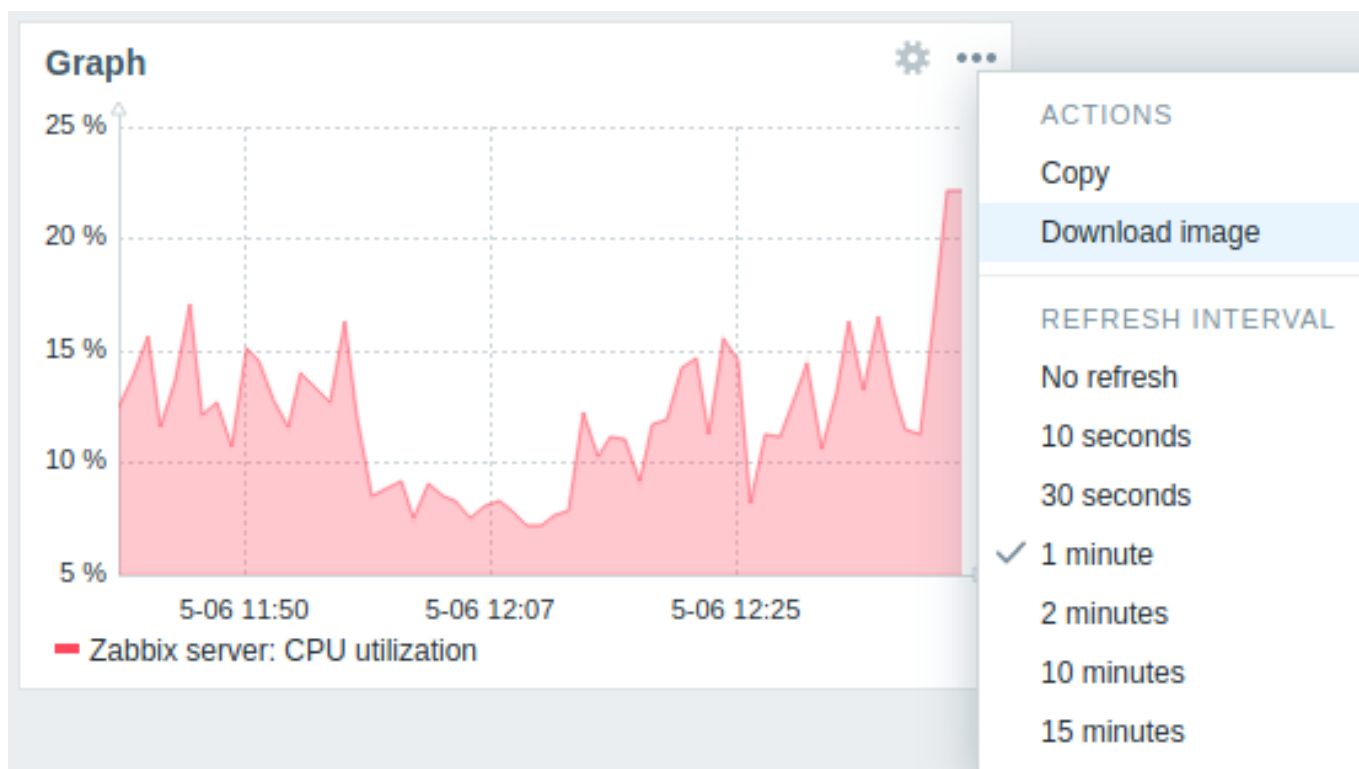

Overrides are useful when several items are selected for a data set using the * wildcard and you want to change how the items are displayed by default (e.g. default base color or any other property).

Existing overrides (if any) are displayed in a list. To add a new override:

- Click on the **+ Add new override** button
- Select hosts and items for the override. Alternatively, you may enter host and item patterns. Wildcard patterns may be used (for example, * will return results that match zero or more characters). To specify a wildcard pattern, just enter the string manually and press *Enter*. While you are typing, note how all matching hosts are displayed in the dropdown. The wildcard symbol is always interpreted, therefore it is not possible to add, for example, an item named "item*" individually if there are other matching items (e.g. item2, item3). Host pattern and item pattern parameters are mandatory. The parameter for specifying host patterns is not available when configuring the widget on a **template dashboard**. The parameter for specifying an item list allows to select only **items configured on the template** when configuring the widget on a **template dashboard**.
- Click on **+**, to select override parameters. At least one override parameter should be selected. For parameter descriptions, see the *Data set* tab above.

Information displayed by the graph widget can be downloaded as a .png image using the **widget menu**:

A screenshot of the widget will be saved to the Downloads folder.

9 Graph (classic)

Overview

In the classic graph widget, you can display a single custom graph or simple graph.

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|---------------|---|
| Source | Select the graph type: Graph - custom graph; Simple graph - simple graph. |
| Graph | Select the custom graph to display. Alternatively, select a compatible widget as the data source for graphs. This parameter is available if <i>Source</i> is set to "Graph". |
| Item | Select the item to display in a simple graph. Alternatively, select a compatible widget as the data source for items. This parameter is available if <i>Source</i> is set to "Simple graph". |
| Time period | Set a time period for which to display data in the graph. Select the data source for the time period: Dashboard - set the <i>Time period</i> selector as the data source; Widget - set a compatible widget specified in the <i>Widget</i> parameter as the data source; Custom - set the time period specified in the <i>From</i> and <i>To</i> parameters as the data source; if set, a clock icon will be displayed in the top right corner of the widget, indicating the set time on mouseover. |
| Widget | Enter or select a compatible widget as the data source for the time period. This parameter is available if <i>Time period</i> is set to "Widget". |
| From | Enter or select the start of the time period. Relative time syntax (now, now/d, now/w-1w, etc.) is supported. This parameter is available if <i>Time period</i> is set to "Custom". |
| To | Enter or select the end of the time period. Relative time syntax (now, now/d, now/w-1w, etc.) is supported. This parameter is available if <i>Time period</i> is set to "Custom". |
| Show legend | Unmark this checkbox to hide the legend on the graph (marked by default). |
| Override host | Select a compatible widget or the dashboard as the data source for hosts. This parameter is not available when configuring the widget on a template dashboard . |

Information displayed by the classic graph widget can be downloaded as .png image using the **widget menu**:

A screenshot of the widget will be saved to the *Downloads* folder.

10 Graph prototype

Overview

In the graph prototype widget, you can display a grid of graphs created from either a graph prototype or an item prototype by low-level discovery.

Configuration

To configure, select *Graph prototype* as widget type:

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|------------------------|--|
| <i>Source</i> | Select the source of the graphs: Graph prototype or Simple graph prototype . |
| <i>Graph prototype</i> | Select a graph prototype to display graphs discovered by the graph prototype. This parameter is available if <i>Source</i> is set to "Graph prototype". |
| <i>Item prototype</i> | Select an item prototype to display simple graphs for items discovered by the item prototype. This parameter is available if <i>Source</i> is set to "Simple graph prototype". |
| <i>Time period</i> | Set a time period for which to display data in the graphs. Select the data source for the time period: Dashboard - set the <i>Time period</i> selector as the data source; Widget - set a compatible widget specified in the <i>Widget</i> parameter as the data source; Custom - set the time period specified in the <i>From</i> and <i>To</i> parameters as the data source; if set, a clock icon will be displayed in the top right corner of the widget, indicating the set time on mouseover. |
| <i>Widget</i> | Enter or select a compatible widget as the data source for the time period. This parameter is available if <i>Time period</i> is set to "Widget". |
| <i>From</i> | Enter or select the start of the time period. Relative time syntax (<code>now</code> , <code>now/d</code> , <code>now/w-1w</code> , etc.) is supported. This parameter is available if <i>Time period</i> is set to "Custom". |
| <i>To</i> | Enter or select the end of the time period. Relative time syntax (<code>now</code> , <code>now/d</code> , <code>now/w-1w</code> , etc.) is supported. This parameter is available if <i>Time period</i> is set to "Custom". |
| <i>Show legend</i> | Unmark this checkbox to hide the legend on the graphs (marked by default). |
| <i>Override host</i> | Select a compatible widget or the dashboard as the data source for hosts. This parameter is not available when configuring the widget on a template dashboard . |
| <i>Columns</i> | Enter the number of columns of graphs to display within a graph prototype widget. |
| <i>Rows</i> | Enter the number of rows of graphs to display within a graph prototype widget. |

While the *Columns* and *Rows* parameters allow fitting more than one graph in the widget, there still may be more discovered graphs than there are columns/rows in the widget. In this case, paging becomes available in the widget, and a slide-up header allows to switch between pages using the left and right arrows:

11 Honeycomb

Overview

The honeycomb widget offers a dynamic overview of the monitored network infrastructure and resources, where host groups, such as virtual machines and network devices, along with their respective items, are visually represented as interactive hexagonal cells.

Honeycomb

The widget can be visually fine-tuned using the [advanced configuration](#) options to create a wide variety of visual styles.

vm-cluster-01: CPU utilization

On mouseover, the focused honeycomb cell enlarges for improved visibility. Clicking a cell highlights its border until another cell is selected.

The number of displayed honeycomb cells is constrained by the widget's size and the minimum cell size (32 pixels). If all cells cannot fit within the widget, an ellipsis is shown as the final cell.

The widget can be resized to fit more cells. On resize, the honeycomb cell size and positioning are dynamically adjusted. Each row in the honeycomb will maintain an equal cell count, except for the last row if the total cell count is not divisible by the row's cell count.

Configuration

To configure, select *Honeycomb* as type:

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|--------------------|--|
| <i>Host groups</i> | <p>Select host groups.</p> <p>Alternatively, select a compatible widget as the data source for host groups.</p> <p>This field is auto-complete, so starting to type the name of a group will offer a dropdown of matching groups.</p> <p>Selecting a parent host group implicitly selects all nested host groups; if no host groups are selected, the widget will display all host groups containing hosts with items matching the selected <i>Item pattern</i> (see below).</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |
| <i>Hosts</i> | <p>Select hosts.</p> <p>Alternatively, select a compatible widget or the dashboard as the data source for hosts.</p> <p>This field is auto-complete, so starting to type the name of a host will offer a dropdown of matching hosts.</p> <p>If no hosts are selected, the widget will display all hosts with items matching the selected <i>Item pattern</i> (see below).</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |

| | |
|----------------------------------|--|
| <i>Host tags</i> | <p>Specify tags to limit the number of hosts displayed in the widget.</p> <p>It is possible to include as well as exclude specific tags and tag values. Several conditions can be set.</p> <p>Tag name matching is always case-sensitive.</p> <p>There are several operators available for each condition:</p> <p>Exists - include the specified tag names;</p> <p>Equals - include the specified tag names and values (case-sensitive);</p> <p>Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive);</p> <p>Does not exist - exclude the specified tag names;</p> <p>Does not equal - exclude the specified tag names and values (case-sensitive);</p> <p>Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).</p> <p>There are two calculation types for conditions:</p> <p>And/Or - all conditions must be met, conditions having the same tag name will be grouped by the Or condition;</p> <p>Or - enough if one condition is met.</p> |
| <i>Item patterns</i> | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Enter item patterns or select existing items as item patterns. Data of items that match the entered or selected patterns will be displayed on the honeycomb. The <i>Item patterns</i> parameter is mandatory.</p> <p>Wildcard patterns may be used for selection (for example, * will return items that match zero or more characters; Zabbix* will return items that start with "Zabbix").</p> <p>To specify a wildcard pattern, enter the string manually and press <i>Enter</i>. When you start typing, a dropdown list will show matching items limited to those belonging to selected <i>Hosts</i> or hosts within selected <i>Host groups</i>, if any. The wildcard symbol is always interpreted, therefore, it is not possible to add, for example, an item named <i>item*</i> individually, if there are other matching items (e.g., item2, item3).</p> <p>When configuring the widget on a template dashboard, this parameter allows selecting only items configured on the template.</p> |
| <i>Item tags</i> | Specify tags to limit the number of items displayed in the widget. For more information, see <i>Host tags</i> above. |
| <i>Show hosts in maintenance</i> | <p>Mark this checkbox to display hosts in maintenance (in this case, maintenance icon will be shown next to the host name).</p> <p>This parameter is labeled <i>Show data in maintenance</i> when configuring the widget on a template dashboard.</p> |
| <i>Show</i> | <p>Mark this checkbox to display the respective honeycomb cell element - primary label, secondary label.</p> <p>At least one element must be selected.</p> |
| <i>Advanced configuration</i> | Click the <i>Advanced configuration</i> label to display advanced configuration options. |

Advanced configuration

Advanced configuration options are available in the collapsible *Advanced configuration* section and only for elements selected in the *Show* field (see above) and the background color or thresholds for honeycomb cells.

Select the label type:

Text - the label will display the text specified in the *Text* parameter;

Value - the label will display the item value with decimal places as specified in the *Decimal places* parameter.

Text

Enter the label text. This text may override the default item name.

Multiline text is supported. A combination of text and **supported macros** is possible.

{HOST.*}, {ITEM.*}, {INVENTORY.*}, and **user macros** are supported.

Honeycomb cells are ordered alphabetically by host name, and, within each host, by item name.

This parameter is available if *Type* is set to "Text".

Decimal places

Enter the number of decimal places to display with the value.

This parameter is available if *Type* is set to "Value", and affects only items that return **numeric (float)** data.

Size

Select the label size:

Auto - use automatically adjusted label size;

Custom - enter a custom label size (in percent, relative to the honeycomb cell size).

Note that labels that do not fit the honeycomb cell size are truncated.

Bold

Mark the checkbox to display item units in bold.

Color

Select the item units color from the color picker.

"D" stands for the default color, which depends on the frontend theme. To return to the default color, click the *Use default* button in the color picker.

Units

Units

Mark the checkbox to display units with the item value.

If you enter a unit name, it will override the units set in the **item configuration**.

This parameter is available if *Type* is set to "Text".

Position

Select the position of the item units (before or after the item value).

This parameter is ignored for the following **time-related units**: unixtime, uptime, s.

This parameter is available if *Type* is set to "Text".

Background color

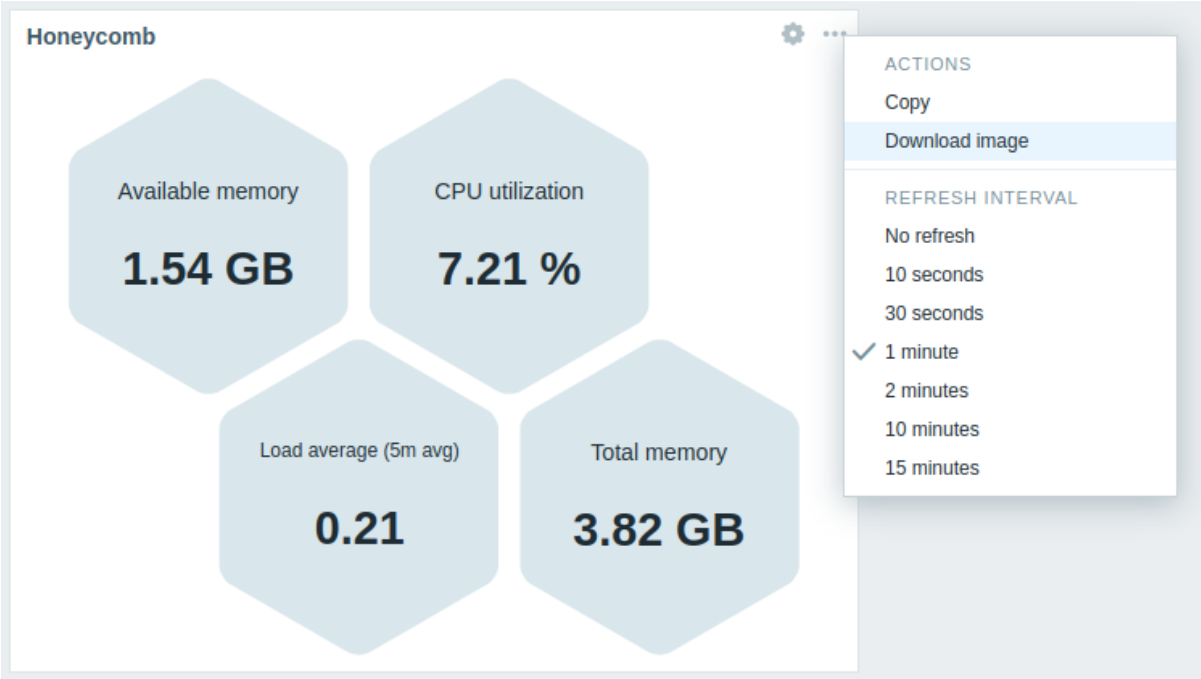

Background color Select the honeycomb cells background color from the color picker.
"D" stands for the default color, which depends on the frontend theme. To return to the default color, click the *Use default* button in the color picker.

Thresholds

Color interpolation Mark the checkbox to enable smooth transitioning between threshold colors for honeycomb cells. This parameter is available if two or more thresholds are set.

Threshold Click *Add* to add a threshold, select a threshold color from the color picker, and specify a numeric value.
The thresholds list will be sorted in ascending order when saved.
Note that the colors configured as thresholds will be displayed correctly only for numeric items.
Suffixes (for example, "1d", "2w", "4K", "8G") are supported. **Value mappings** are supported.

The information displayed by the honeycomb widget can be downloaded as a .png image using the **widget menu**:

A screenshot of the widget will be saved to the *Downloads* folder.

12 Host availability

Overview

In the host availability widget, high-level statistics about host availability are displayed in colored columns/lines, depending on the chosen layout.

Horizontal display (columns):

Vertical display (lines):

Host availability in each column/line is counted as follows:

- *Available* - hosts with all interfaces available
- *Not available* - hosts with all interfaces not available
- *Mixed* - hosts with at least one interface unavailable and at least one either available or unknown; others can have any value, including "unknown"
- *Unknown* - hosts with at least one interface unknown (none unavailable)
- *Total* - total of all hosts

Note:

For Zabbix agent (active checks), the *Mixed* cell will always be empty since this type of items cannot have multiple interfaces.

Configuration

To configure, select *Host availability* as type:

The 'Add widget' configuration form for 'Host availability' includes the following fields and options:

- Type:** Host availability (dropdown)
- Show header:** ☒
- Name:** default (text input)
- Refresh interval:** Default (15 minutes) (dropdown)
- Host groups:** type here to search (text input) with a **Select** button and a dropdown arrow.
- Interface type:** ☐ Zabbix agent (active checks), ☐ Zabbix agent (passive checks), ☐ SNMP, ☐ JMX, ☐ IPMI.
- Layout:** Horizontal (selected) and Vertical (button).
- Include hosts in maintenance:** ☐
- Show only totals:** ☐
- Buttons:** Add (blue), Cancel (white with blue border).

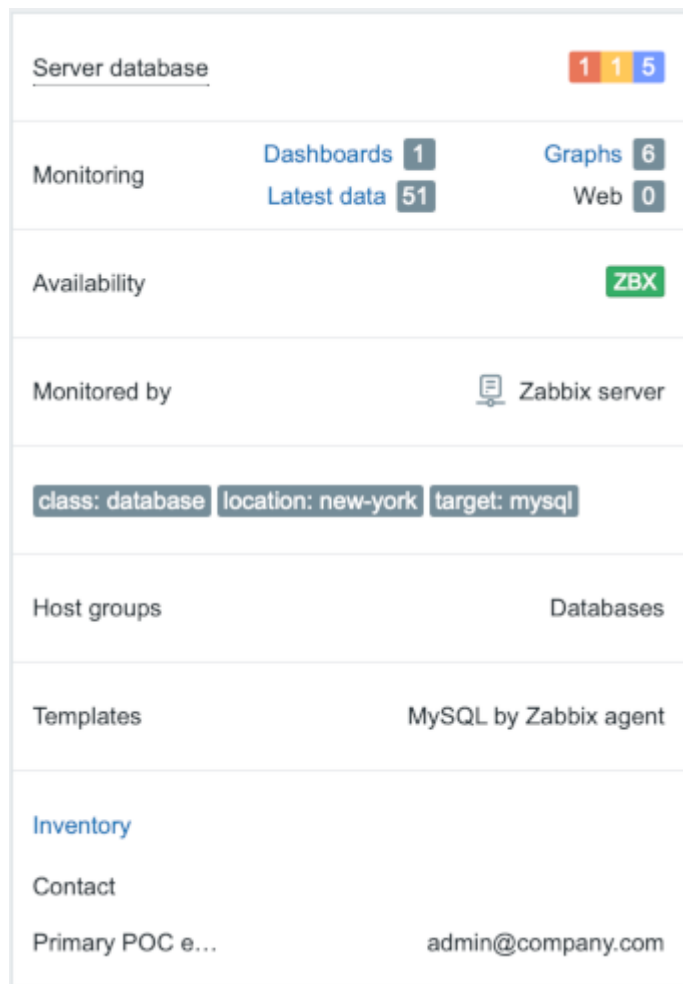

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|-------------------------------------|---|
| <i>Host groups</i> | Select host groups. Alternatively, select a compatible widget as the data source for host groups. This field is auto-complete, so starting to type the name of a group will offer a dropdown of matching groups. This parameter is not available when configuring the widget on a template dashboard . |
| <i>Interface type</i> | Select which host interfaces you want to see availability data for. Availability of all interfaces is displayed by default if nothing is selected. |
| <i>Layout</i> | Select horizontal display (columns) or vertical display (lines). |
| <i>Include hosts in maintenance</i> | Include hosts that are in maintenance in the statistics. This parameter is labeled <i>Show data in maintenance</i> when configuring the widget on a template dashboard . |
| <i>Show only totals</i> | If checked, the total of hosts, without breakdown by interfaces, is displayed. This option is disabled if only one interface is selected. |

13 Host card

Overview

The Host card widget provides comprehensive and customizable information about a single host. The host can be specified through the widget configuration, selected from another compatible widget, or located using the host selector at the dashboard level.

Top part of the widget contains the name of a host and the number of host problems grouped by severity. If a host is disabled, the text *Disabled* will be written next to the host name. If a host is in maintenance, the maintenance icon will be displayed next to the host name. Other sections of the widget can be customized as required.

This widget automatically adjusts the layout based on the width. To rearrange widget sections into multiple columns, expand the widget horizontally.

Configuration

To configure, select *Host card* as type:

In addition to the parameters that are **common** for all widgets, you may set the following specific parameters:

| | |
|--------------------------|---|
| Host | Select the host. Alternatively, select a compatible widget or the dashboard as the data source . This field provides matching suggestions as you start typing a name. You can also press the Select button to choose manually. |
| Show suppressed problems | This parameter is not available when configuring the widget on a template dashboard . Mark this checkbox to include suppressed problems into problem calculation. |
| Show | Configure up to eight sections to be displayed by the widget. The sections can be rearranged by dragging and dropping. |
| Host groups | Host groups the host belongs to. |
| Description | Host description. |
| Monitoring | Quick links for navigating to dashboards, latest data, graphs, and web scenarios of the host. The number next to each link indicates the number of entities. |
| Availability | Host availability by interface. |
| Monitored by | Zabbix server, proxy, or proxy group the host is monitored by. |
| Templates | Templates linked to the host. |
| Inventory | Display host inventory fields. If selected, an <i>Inventory fields</i> parameter will appear, allowing to specify which fields should be displayed. |
| Tags | Host tags. |

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|----------------------|---|
| <i>Host groups</i> | <p>Select host groups.</p> <p>Alternatively, select a compatible widget as the data source for host groups.</p> <p>This field is auto-complete, so starting to type the name of a group will offer a dropdown of matching groups.</p> <p>Selecting a parent host group implicitly selects all nested host groups; if no host groups are selected, the widget will display all hosts from all host groups.</p> |
| <i>Host patterns</i> | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Enter host patterns or select existing hosts as host patterns. Hosts that match the specified patterns will be displayed on the host navigator.</p> <p>This field is auto-complete, so starting to type the name of a host will offer a dropdown of matching hosts.</p> <p>If no hosts are selected, the widget will display all hosts.</p> <p>Wildcard patterns may be used for selection (for example, <code>*</code> will return hosts that match zero or more characters; <code>Zabbix*</code> will return hosts that start with "Zabbix").</p> <p>To specify a wildcard pattern, enter the string manually and press <i>Enter</i>. When you start typing, a dropdown list will show matching hosts limited to those belonging to hosts within selected <i>Host groups</i>, if any.</p> |
| <i>Host status</i> | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Filter which hosts to display based on their status (any, enabled, disabled).</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |

| | |
|----------------------------------|---|
| <i>Host tags</i> | <p>Specify tags to filter the hosts displayed in the widget.</p> <p>It is possible to include as well as exclude specific tags and tag values. Several conditions can be set.</p> <p>Tag name matching is always case-sensitive.</p> <p>There are several operators available for each condition:</p> <p>Exists - include the specified tag names;</p> <p>Equals - include the specified tag names and values (case-sensitive);</p> <p>Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive);</p> <p>Does not exist - exclude the specified tag names;</p> <p>Does not equal - exclude the specified tag names and values (case-sensitive);</p> <p>Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).</p> <p>There are two calculation types for conditions:</p> <p>And/Or - all conditions must be met, conditions having the same tag name will be grouped by the Or condition;</p> <p>Or - enough if one condition is met.</p> |
| <i>Severity</i> | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Mark problem severities to filter hosts with problems to be displayed in the widget.</p> <p>If no severities are marked, all hosts with all problems will be displayed.</p> |
| <i>Show hosts in maintenance</i> | <p>Mark this checkbox to display hosts in maintenance (in this case, maintenance icon will be shown next to the host name).</p> |
| <i>Show problems</i> | <p>This parameter is labeled <i>Show data in maintenance</i> when configuring the widget on a template dashboard.</p> <p>Filter which problems to display with the hosts in the widget based on their status (all, unsuppressed, none).</p> |
| <i>Group by</i> | <p>Add a grouping attribute by which to group the selected hosts:</p> <p>Host group - group hosts by their host group;</p> <p>Tag value - enter a tag name to group hosts by the values of this tag (for example, enter "city" to group hosts by values "Riga", "Tokyo", etc.);</p> <p>Severity - group hosts by their problem severities.</p> <p>If <i>Show problems</i> is configured to display problems, they are displayed as follows:</p> <ul style="list-style-type: none"> - for each severity group, only the corresponding problem count is displayed; - for each host, all its problem counts are displayed. <p>Note that hosts will be grouped only by those severities marked in the <i>Severity</i> parameter; if no severities are marked, all hosts will be grouped by all severities.</p> <p>Grouping attributes can be reordered by dragging up or down by the handle before the group name. Note that grouping attribute order determines group nesting order. For example, specifying multiple tag names (1: color, 2: city) will result in hosts being grouped by color (red, blue, etc.) and then by city (Riga, Tokyo, etc.).</p> <p>A host may be displayed in multiple groups depending on the configured grouping attributes (for example, when grouping by host group and the host belongs to multiple host groups). Clicking such hosts selects and highlights them in all groups.</p> <p>Hosts that do not match the configured grouping attributes are displayed in the <i>Uncategorized</i> group.</p> <p>Up to 10 grouping attributes can be specified, and all must be unique.</p> <p>If no grouping attributes are specified, hosts will not be grouped.</p> |

Host limit

Enter the maximum number of hosts to be displayed. Possible values range from 1-9999.

When more hosts are available for displaying than the set limit, a corresponding message is shown below the displayed hosts (for example, "100 of 100+ hosts are shown").

Note that the configured host limit also affects the display of configured groups; for example, if host limit is set to 100 and hosts are grouped by tag values (more than 200), only the first 100 tag values with the corresponding hosts will be displayed in the widget.

This parameter is not affected by the *Limit for search and filter results* parameter in *Administration* → *General* → *GUI*.

This parameter is not available when configuring the widget on a **template dashboard**.

15 Item history

Overview

The item history widget displays the latest data for various item types (numeric, character, log, text, and binary) in a table format. It can also show progress bars, images for binary data types (useful for **browser items**), and highlight values (useful for **log file monitoring**).

Common column parameters:

| | |
|-------------------|---|
| <i>Name</i> | Enter the name of the column. If left empty, the item name from the <i>Item</i> parameter is used. |
| <i>Item</i> | Select the item. Note that column configuration parameters vary based on the information type of the selected item; for more information, see individual parameters below. When configuring the widget on a template dashboard , only items configured on the template can be selected. |
| <i>Base color</i> | Select the column's background color or fill color if <i>Display</i> is set to "Bar" or "Indicators". Note that the base color can be overridden by threshold or highlight colors. |

Column parameters specific to numeric type items:

| | |
|----------------|--|
| <i>Display</i> | Select how the item value should be displayed: As is - as regular text; Bar - as solid, color-filled bar; Indicators - as segmented, color-filled bar. |
| <i>Min</i> | Enter the minimum value for bar/indicators. If left empty, the widget will use the minimum value of the item. |
| <i>Max</i> | This parameter is available only when <i>Display</i> is set to "Bar" or "Indicators". Enter the maximum value for bar/indicators. If left empty, the widget will use the maximum value of the item. This parameter is available only when <i>Display</i> is set to "Bar" or "Indicators". |

| | |
|---------------------|---|
| <i>Thresholds</i> | Click <i>Add</i> to add a threshold, select a threshold color from the color picker, and specify a numeric value. The thresholds list will be sorted in ascending order when saved. |
| <i>History data</i> | Suffixes (for example, "1d", "2w", "4K", "8G") are supported. Value mappings are supported. Select whether to take data from history or trends: Auto - automatic selection; History - take history data; Trends - take trend data. |

Column parameters specific to character, text, and log type items:

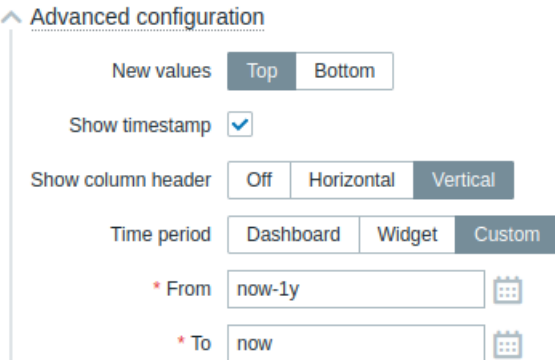

| | |
|---------------------------|--|
| <i>Highlights</i> | Click <i>Add</i> to add a highlight, select a highlight color from the color picker, and specify a regular expression. The selected color will be used as the background color for item values where the specified regular expression matches the text. |
| <i>Display</i> | Select how the item value should be displayed: As is - displayed as is: - linebreaks are observed if the incoming value has line returns; - no word wrapping with horizontal layout or vertical layout with one column; word wrapping with vertical layout and more than one column. Hovering or clicking on the value opens a pop-up with the value. HTML - as HTML text; Single line - as a single line, truncated to a specified length (1-500 characters). Hovering or clicking on the truncated value opens a pop-up with the full value. |
| <i>Use monospace font</i> | Mark this checkbox to display the item value in monospace font (unmarked by default). |
| <i>Display local time</i> | Mark this checkbox to display local time instead of timestamp in the timestamp column. Note that the <i>Show timestamp</i> checkbox in advanced configuration must also be marked. This parameter is available only for log type items. |

Column parameters specific to binary type items:

| | |
|-----------------------|---|
| <i>Show thumbnail</i> | Mark this checkbox to display a thumbnail for image binaries or a "Show" option for non-image binaries. Unmark this checkbox to display a "Show" option for all binary item values. Hovering or clicking the "Show" option opens a pop-up window with the item value (image or Base64 string). If the item value is an empty string, the "Show" option is displayed; hovering or clicking it opens a pop-up containing "Empty string". |
|-----------------------|---|

Advanced configuration

Advanced configuration options are available in the collapsible *Advanced configuration* section:

Advanced configuration

New values:

Show timestamp: ☒

Show column header:

Time period:

* From:

* To:

| | |
|-----------------------|---|
| <i>New values</i> | Select where new item values should be added: Top - at the top of columns; Bottom - at the bottom of columns. |
| <i>Show timestamp</i> | Mark this checkbox to display the timestamp column (unmarked by default). |

| | |
|---------------------------|--|
| <i>Show column header</i> | Select the column header orientation: Off - hide the header; Horizontal - display the header horizontally; Vertical - display the header vertically. |
| <i>Time period</i> | Select the data source for the time period: Dashboard - set the <i>Time period selector</i> as the data source; Widget - set a compatible widget specified in the <i>Widget</i> parameter as the data source; Custom - set the time period specified in the <i>From</i> and <i>To</i> parameters as the data source; if set, a clock icon will be displayed in the top right corner of the widget, indicating the set time on mouseover. |
| <i>Widget</i> | Enter or select a compatible widget (<i>Graph</i> , <i>Graph (classic)</i> , <i>Graph prototype</i>) as the data source for the time period. |
| <i>From</i> | This parameter is available if <i>Time period</i> is set to "Widget". Enter or select the start of the time period. Relative time syntax (<i>now</i> , <i>now/d</i> , <i>now/w-1w</i> , etc.) is supported. |
| <i>To</i> | This parameter is available if <i>Time period</i> is set to "Custom". Enter or select the end of the time period. Relative time syntax (<i>now</i> , <i>now/d</i> , <i>now/w-1w</i> , etc.) is supported. This parameter is available if <i>Time period</i> is set to "Custom". |

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|-------------|--|
| Host groups | <p>Select host groups.</p> <p>Alternatively, select a compatible widget as the data source for host groups.</p> <p>This field is auto-complete, so starting to type the name of a group will offer a dropdown of matching groups.</p> <p>Selecting a parent host group implicitly selects all nested host groups; if no host groups are selected, the widget will display items belonging to all hosts from all host groups.</p> |
| Hosts | <p>This parameter is not available when configuring the widget on a template dashboard.</p> <p>Select hosts.</p> <p>Alternatively, select a compatible widget or the dashboard as the data source for hosts.</p> <p>This field is auto-complete, so starting to type the name of a host will offer a dropdown of matching hosts.</p> <p>If no hosts are selected, the widget will display items belonging to all hosts.</p> <p>This parameter is not available when configuring the widget on a template dashboard.</p> |

Host tags

Specify tags to filter the items displayed in the widget.

It is possible to include as well as exclude specific tags and tag values. Several conditions can be set.

Tag name matching is always case-sensitive.

There are several operators available for each condition:

Exists - include the specified tag names;

Equals - include the specified tag names and values (case-sensitive);

Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive);

Does not exist - exclude the specified tag names;

Does not equal - exclude the specified tag names and values (case-sensitive);

Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).

There are two calculation types for conditions:

And/Or - all conditions must be met, conditions having the same tag name will be grouped by the Or condition;

Or - enough if one condition is met.

Item patterns

This parameter is not available when configuring the widget on a **template dashboard**.

Enter item patterns or select existing items as item patterns. Items that match the specified patterns will be displayed on the item navigator.

Wildcard patterns may be used for selection (for example, * will return items that match zero or more characters; Zabbix* will return items that start with "Zabbix").

To specify a wildcard pattern, enter the string manually and press *Enter*. When you start typing, a dropdown list will show matching items limited to those belonging to selected *Hosts* or hosts within selected *Host groups*, if any. The wildcard symbol is always interpreted, therefore, it is not possible to add, for example, an item named *item** individually, if there are other matching items (e.g., item2, item3).

When configuring the widget on a **template dashboard**, this parameter allows selecting only **items configured on the template**.

Item tags

Specify tags to filter the items displayed in the widget.

It is possible to include as well as exclude specific tags and tag values. Several conditions can be set.

Tag name matching is always case-sensitive.

There are several operators available for each condition:

Exists - include the specified tag names;

Equals - include the specified tag names and values (case-sensitive);

Contains - include the specified tag names where the tag values contain the entered string (substring match, case-insensitive);

Does not exist - exclude the specified tag names;

Does not equal - exclude the specified tag names and values (case-sensitive);

Does not contain - exclude the specified tag names where the tag values contain the entered string (substring match, case-insensitive).

There are two calculation types for conditions:

And/Or - all conditions must be met, conditions having the same tag name will be grouped by the Or condition;

Or - enough if one condition is met.

State

Filter which items to display based on their state (all, normal, not supported).

Show problems

Filter which problems to display with items based on their status (all, unsuppressed, none).

Group by

Add a grouping attribute by which to group items:

Host group - group items by host groups of their hosts;

Host name - group items by their hosts;

Host tag value - enter a tag name to group items by the values of this host tag (for example, enter "city" to group items by values "Riga", "Tokyo", etc.);

Item tag value - enter a tag name to group items by the values of this item tag (for example, enter "component" to group items by values "cpu", "memory", etc.).

Grouping attributes can be reordered by dragging up or down by the handle before the group name. Note that grouping attribute order determines group nesting order. For example, specifying multiple host tag names (1: color, 2: city) will result in items being grouped by color (red, blue, etc.) and then by city (Riga, Tokyo, etc.).

An item may be displayed in multiple groups depending on the configured grouping attributes (for example, when grouping by host group and the item's host belongs to multiple host groups). Clicking such items selects and highlights them in all groups.

Items that do not match the configured grouping attributes are displayed in the *Uncategorized* group.

If *Show problems* is configured to display problems, they are displayed as follows:

- for each group, all subordinate item problem count is displayed;
- for each item, only its problem count is displayed.

Up to 10 grouping attributes can be specified, and all must be unique.

If no grouping attributes are specified, items will not be grouped.

Item limit

Enter the maximum number of items to be displayed. Possible values range from 1-9999.

When more items are available for displaying than the set limit, a corresponding message is shown below the displayed items (for example, "100 of 100+ items are shown").

Note that the configured item limit also affects the display of configured groups; for example, if item limit is set to 100 and items are grouped by their hosts (each containing 200 items), only the first host with its 100 items will be displayed in the widget.

This parameter is not affected by the *Limit for search and filter results* parameter in *Administration → General → GUI*.

17 Item value

Overview

This widget is useful for displaying the value of a single item prominently. This can be the latest value as well as an aggregated value for some period in the past.

Besides the value itself, additional elements can be displayed, if desired:

- Time of the metric
- Item description
- Change indicator for the value
- Background color for the value
- Item unit
- Sparkline chart for values from the specified time period

The widget can display numeric and string values. Displaying binary values is not supported. String values are displayed on a single line and truncated, if needed. "No data" is displayed, if there is no value for the item.

The change indicator always compares with the same period in the past. So, for example, the latest value will be compared with the previous value, while the latest month will be compared with the month before. Note that the previous period for aggregations is calculated as time period of the same length as the original one with ending time directly before the starting time of the original period.

Clicking on the value leads to an **ad-hoc graph** for numeric items or latest data for string items.

The widget and all elements in it can be visually fine-tuned using **advanced configuration** options, allowing to create a wide variety of visual styles:

Configuration

To configure, select *Item value* as the widget type:

Add widget

Cancel

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|-------------------------------|--|
| <i>Item</i> | Select the item. Alternatively, select a compatible widget as the data source for items. |
| <i>Show</i> | Mark the checkbox to display the respective element: description , value , time , change indicator , sparkline . Unmark to hide. At least one element must be selected. |
| <i>Override host</i> | Select a compatible widget or the dashboard as the data source for hosts. |
| <i>Advanced configuration</i> | This parameter is not available when configuring the widget on a template dashboard . Click the <i>Advanced configuration</i> label to display advanced configuration options. |

Advanced configuration

Advanced configuration options are available in the collapsible *Advanced configuration* section, and only for those elements that are selected in the *Show* field (see above).

Note that multiple elements cannot occupy the same space; if they are placed in the same space, an error message will be displayed.

Generic widget parameters

These parameters determine the background color (static or dynamic) for the whole widget and an aggregation function for displaying values.

| | |
|-----------------------------|---|
| <i>Background color</i> | Select the background color for the whole widget from the color picker. D stands for default color (depends on the frontend theme). To return to the default value, click the <i>Use default</i> button in the color picker. |
| <i>Thresholds</i> | Configure the dynamic background color for the whole widget. Click <i>Add</i> to add a threshold, select the background color from the color picker, and specify a numeric value. Once the item value equals or is greater than the threshold value, the background color will change. The list will be sorted in ascending order when saved. |
| <i>Aggregation function</i> | Note that the dynamic background color will be displayed correctly only for numeric items. Specify which aggregation function to use: min - display the smallest value; max - display the largest value; avg - display the average value; count - display the count of values; sum - display the sum of values; first - display the first value; last - display the last value; not used - display the most recent value (no aggregation). Aggregation allows to display an aggregated value for the chosen interval (5 minutes, an hour, a day), instead of the most recent value. Only numeric data can be displayed for <i>min</i> , <i>max</i> , <i>avg</i> and <i>sum</i> . For <i>count</i> , non-numeric data will be changed to numeric. |
| <i>Time period</i> | Specify the time period to use for aggregating values: Dashboard - use time period of the dashboard; Widget - use time period of the specified widget; Custom - use a custom time period. <This parameter will not be displayed if <i>Aggregation function</i> is set to "not used". |
| <i>Widget</i> | Select the widget. This parameter will only be displayed if <i>Time period</i> is set to "Widget". |
| <i>From</i> | Select the time period from (default value <code>now-1h</code>). See relative time syntax . This parameter will only be displayed if <i>Time period</i> is set to "Custom". |
| <i>To</i> | Select the time period to (default value <code>now</code>). See relative time syntax . This parameter will only be displayed if <i>Time period</i> is set to "Custom". |
| <i>History data</i> | Take data from history or trends: Auto - automatic selection; History - take history data; Trends - take trend data. This setting applies only to numeric data. Non-numeric data will always be taken from history. |

Description

These parameters determine how the item description should be displayed.

☐

Color

D

| | |
|----------------------------|---|
| <i>Decimal places</i> | Select how many decimal places will be displayed with the value. This value will affect only float items. For items with units set to "s", if this value is greater than 0 (the default is 2), the widget rounds the most significant time unit and displays a numeric value (e.g. "10.43m") instead of converting the value into a full time string. When set to 0, the seconds are converted to a human-readable time string (for example, "4h 56m 30s"). |
| <i>Size</i> | Enter font size height for the decimal places (in percent relative to total widget height). |
| <i>Horizontal position</i> | Select horizontal position of the item value - left, right or center. |
| <i>Vertical position</i> | Select vertical position of the item value - top, bottom or middle. |
| <i>Size</i> | Enter font size height for the item value (in percent relative to total widget height). Note that the size of item value is prioritized; other elements have to concede space for the value. With the change indicator though, if the value is too large, it will be truncated to show the change indicator. |
| <i>Bold</i> | Mark the checkbox to display item value in bold type. |
| <i>Color</i> | Select the item value color from the color picker. D stands for default color (depends on the frontend theme). To return to the default value, click the <i>Use default</i> button in the color picker. |
| Units | |
| <i>Units</i> | Mark the checkbox to display units with the item value. If you enter a unit name, it will override the unit from item configuration. |
| <i>Position</i> | Select the item unit position - above, below, before or after the value. |
| <i>Size</i> | Enter font size height for the item unit (in percent relative to total widget height). |
| <i>Bold</i> | Mark the checkbox to display item unit in bold type. |
| <i>Color</i> | Select the item unit color from the color picker. D stands for default color (depends on the frontend theme). To return to the default value, click the <i>Use default</i> button in the color picker. |

Time

These parameters determine how the time (clock value from the item history) should be displayed.

| <i>Vertical position</i> | Select vertical position of the time - top, bottom or middle. |
| <i>Size</i> | Enter font size height for the time (in percent relative to total widget height). |
| <i>Bold</i> | Mark the checkbox to display time in bold type. |
| <i>Color</i> | Select the time color from the color picker. D stands for default color (depends on the frontend theme). To return to the default value, click the <i>Use default</i> button in the color picker. |

Change indicator

This section allows to select the color of change indicators from the color picker.

Change indicator

↑

↓

↕

The change indicators are as follows:

- ↑ - item value is up (for numeric items)
- ↓ - item value is down (for numeric items)
- ↕ - item value has changed (for string items and items with value mapping)

D stands for default color (depends on the frontend theme). To return to the default value, click the *Use default* button in the color picker.

Vertical size of the change indicator is equal to the size of the value (integer part of the value for numeric items).

Note that up and down indicators are not shown with just one value.

Sparkline

These parameters determine how the sparkline chart should be displayed.

| <i>History data</i> | Take data from history or trends: Auto - automatic selection; History - take history data; Trends - take trend data. |

Overview

In the map widget you can display either:

- a single configured network map;
- one of the configured network maps in the **map navigation tree** (when clicking on the map name in the tree).

Configuration

To configure, select *Map* as type:

Add widget ? X

Type Map ☐ Show header ☒

Name

Refresh interval Default (15 minutes) ☐

* Map Local network X Select ☐

Add Cancel

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|------------|---|
| Map | Set a map to display. Alternatively, select a compatible widget as the data source for the map to display. This field is auto-complete, so starting to type the name of the map or widget will offer a dropdown of matching maps or widgets. |
|------------|---|

19 Map navigation tree

Overview

This widget allows building a hierarchy of existing maps while also displaying problem statistics with each included map and map group.

It becomes even more powerful if you link the *Map* widget to the navigation tree. In this case, clicking on a map name in the navigation tree displays the map in full in the *Map* widget.

Statistics with the top-level map in the hierarchy display a sum of problems of all submaps and their own problems.

Configuration

To configure, select *Map navigation tree* as type:

In addition to the parameters that are **common** for all widgets, you may set the following specific options:

| | |
|------------------------------|--|
| <i>Show unavailable maps</i> | <p>Mark this checkbox to display maps that the user does not have read permission to. Unavailable maps in the navigation tree will be displayed with a grayed-out icon. Note that if this checkbox is marked, available submaps are displayed even if the parent level map is unavailable. If unmarked, available submaps to an unavailable parent map will not be displayed at all.</p> <p>Problem count is calculated based on available maps and available map elements.</p> |
|------------------------------|--|

Navigation tree elements are displayed in a list. You can:

- drag an element (including its child elements) to a new place in the list;
- expand or collapse an element to display or hide its child elements;
- add a child element (with or without a linked map) to an element;
- add multiple child elements (with linked maps) to an element;
- edit an element;
- remove an element (including its child elements).

The following navigation tree element configuration parameters are available:

| | |
|-------------|--|
| Name | Enter the navigation tree element name. |
| Linked map | Select the map to link to the navigation tree element. This field is auto-complete, so starting to type the name of a map will offer a dropdown of matching maps. |
| Add submaps | Mark this checkbox to add the submaps of the linked map as child elements to the navigation tree element. |

20 Pie chart

Overview

The pie chart widget allows to display values of selected items as a **pie** or **doughnut** chart.

Pie chart.

Doughnut chart.

On mouseover, the focused sector enlarges outwards and the legend for this sector is displayed. Clicking on the focused sector makes the pop-out effect permanent, until closed with "x".

The charts are drawn using a vector image drawing technique.

Configuration

To configure, select *Pie chart* as type:

Add Cancel

Data set

The **Data set** tab allows selecting data for the pie chart by adding data sets. Two types of data sets can be added:

- *Item patterns* - data from matching items is displayed. The chart is drawn using different shades of single color for each item.
- *Item list* - data from selected items is displayed. The chart is drawn using different colors for each item.

By default, an *Item patterns* data set is added.

| | |
|----------------------|--|
| Data set | <p>For Item patterns data set:</p> <p>Select or enter host and item patterns; data of items that match the entered patterns will be displayed on the pie chart; up to 50 items may be displayed.</p> <p>Wildcard patterns may be used for selection (for example, * will return results that match zero or more characters).</p> <p>To specify a wildcard pattern, enter the string manually and press <i>Enter</i>.</p> <p>The wildcard symbol is always interpreted, so it is not possible to add, for example, an item named <i>item*</i> individually if there are other matching items (for example, <i>item2</i>, <i>item3</i>).</p> <p>Specifying host and item patterns is mandatory for "Item patterns" data sets.</p> <p>See also: Data set configuration details.</p> <p>For Item list data set:</p> <p>Select items for the pie chart by clicking on the <i>Add item</i> button.</p> <p>The <i>Type</i> dropdown after the item name allows to select the display type for each item:</p> <p>Normal - item value is represented proportionally on the pie chart (default);</p> <p>Total - item value takes up the whole pie chart. Note that only one "Total" item can exist per pie chart, and it will be placed first on the pie chart legend. If an item is set to "Total", the <i>Data set aggregation</i> parameter (see below) will be disabled and set to "not used".</p> <p>You may also select compatible widgets as the data source for items by clicking on the <i>Add widget</i> button. The same options apply to widgets as to individual items.</p> <p>Specifying items or widgets is mandatory for "Item list" data sets.</p> <p>See also: Data set configuration details.</p> <p>Note that only numeric item types are allowed.</p> |
| Aggregation function | <p>When configuring the widget on a template dashboard, the parameter for specifying host patterns is not available, and the parameter for specifying an item list allows to select only the items configured on the template.</p> <p>Specify which aggregation function to use for each item in the data set:</p> <p>min - display the smallest value;</p> <p>max - display the largest value;</p> <p>avg - display the average value;</p> <p>sum - display the sum of values;</p> <p>count - display the count of values;</p> <p>first - display the first value;</p> <p>last - display the last value (default).</p> |
| Data set aggregation | <p>Aggregation allows to display an aggregated value for the interval (5 minutes, an hour, a day) selected in the <i>Time period</i> tab or used for the whole dashboard.</p> <p>Specify which aggregation function to use for the whole data set:</p> <p>not used - no aggregation, items are displayed separately (default);</p> <p>min - display the smallest value;</p> <p>max - display the largest value;</p> <p>avg - display the average value;</p> <p>sum - display the sum of values;</p> <p>count - display the count of values.</p> |
| Data set label | <p>Aggregation allows to display an aggregated value for the interval (5 minutes, an hour, a day) selected in the <i>Time period</i> tab or used for the whole dashboard.</p> <p>Specify a custom label for the data set.</p> <p>The label is displayed in the data set configuration and the pie chart legend (for aggregated data sets).</p> <p>All data sets are numbered including those with a specified <i>Data set label</i>. If no label is specified, the data set will be labeled automatically according to its number (e.g. "Data set #2", "Data set #3", etc.). Data set numbering is recalculated after reordering/dragging data sets.</p> <p>Data set labels that are too long will be shortened to fit where displayed (e.g. "Number of proc...").</p> |

Data set configuration details

Existing data sets are displayed in a list. You can rearrange, expand/collapse, change colors, and clone these data sets.

For more information, see data set configuration details in the *Graph* widget. These details also apply to the *Pie chart* widget.

Displaying options

The **Displaying options** tab allows to define history data selection and visualization options for the pie chart:

| | |
|-------------------------------|---|
| History data selection | Select the data source: Auto - data are sourced according to the classic algorithm (default); History - data from history; Trends - data from trends. |
| Draw | Select the visualization style of the pie chart: Pie - a full pie (sectors take up 100% of the radius); Doughnut - a pie with empty circle in the middle (sectors use up to 50% of radius). Select the space size (in units of 0-10) between sectors (default is "1"). |
| Space between sectors | |
| Merge sectors smaller than N% | Mark the checkbox to merge sectors smaller than the N%. If enabled, select the color for the merged sectors and the percentage threshold (N) for merging small sectors. |
| Width | Select the doughnut width: 20, 30, 40 or 50% (default) of the radius. |
| Stroke width | Select the width of the doughnut sector border (0-10). |
| Show total value | Mark the checkbox to show the total value in the middle of the doughnut chart. |
| Size | Select the size option for the total value: Auto - the text is sized automatically to fit the doughnut middle readably; Custom - specify the text size as height percentage from the total widget height. |
| Decimal places | Specify the number of decimal places for the total value (0-6). |
| Units | Specify the units for the total value. |
| Bold | Mark the checkbox to display the total value in bold. |
| Color | Select the color for the total value. |

Time period

The **Time period** tab allows to set a custom time period for the aggregation settings of the pie chart:

| | |
|--------------------|--|
| <i>Time period</i> | <p>Select the data source for the time period:</p> <p>Dashboard - set the <i>Time period</i> selector as the data source;</p> <p>Widget - set a compatible widget specified in the <i>Widget</i> parameter as the data source;</p> <p>Custom - set the time period specified in the <i>From</i> and <i>To</i> parameters as the data source; if set, a clock icon will be displayed in the top right corner of the widget, indicating the set time on mouseover.</p> |
| <i>Widget</i> | <p>Enter or select a compatible widget (<i>Graph</i>, <i>Graph (classic)</i>, <i>Graph prototype</i>) as the data source for the time period.</p> <p>This parameter is available if <i>Time period</i> is set to "Widget".</p> |
| <i>From</i> | <p>Enter or select the start of the time period.</p> <p>Relative time syntax (<i>now</i>, <i>now/d</i>, <i>now/w-1w</i>, etc.) is supported.</p> <p>This parameter is available if <i>Time period</i> is set to "Custom".</p> |
| <i>To</i> | <p>Enter or select the end of the time period.</p> <p>Relative time syntax (<i>now</i>, <i>now/d</i>, <i>now/w-1w</i>, etc.) is supported.</p> <p>This parameter is available if <i>Time period</i> is set to "Custom".</p> |

Legend

The **Legend** tab allows to customize the pie chart legend:

| | |
|---|---|
| <i>Show legend</i> | Unmark this checkbox to hide the legend on the pie chart (marked by default). |
| <i>Show value</i> | Mark this checkbox to show the value of the item in the legend. |
| <i>Show aggregation function</i> | Mark this checkbox to show the aggregation function in the legend. |
